As to the correct stranding of copper conductors, nearly all manufacturers regard the seven-strand cable as standard. Now the number of wires in each strand should be sufficient to give the cable enough flexibility for the service intended. As locomotives reel and unreel their cable three to four times as often as mining machines the cable used on mine locomotives must necessarily be much more flexible if it is to have long life. The standard practice now with reliable manufacturers is to put at least 19 wires to each strand for locomotive cables, giving a 7x19 cable or 133 wires all told, and on the mining machines a 7x7 or 49-wire cable is found to give good results. A 49-wire cable will not have as long a life on a locomotive as would a 133-wire cable, yet the difference in cost is only 5 per cent.

Life of Cable Depends on Careful Handling

Another important factor in the life of cable is the manner in which it is handled. This is a problem for each individual operator and in the main depends on the experience of the motorman or machine runner who handles the cable. Green men invariably abuse the equipment they handle, but with proper supervision they can be made to take care of their cables; some really remarkable records in fact have come to my notice.

For your information and also a mark to shoot at I will give you herewith a record of an all-rubber-covered cable in use at No. 2 mine of the Clinchfield Coal Corporation at Dante, Va. Mr. Booker, chief electrician of this company advises that he put a No. 3 all-rubber cable on a 5-ton locomotive Sept. 8, 1921. This locomotive gathered coal in the daytime and handled a mining machine at night. The current for this machine was fed through the same locomotive cable, giving a day-and-night service.

Up to Sept. 15, or in a little over one year, this locomotive has hauled 42,300 tons of coal and the machine has cut 47,000 tons of coal, giving a total hauled and cut of 89,300 tons of coal. The first cost of the cable was $70 and 7 splices in that time will add $3.50, or a total cable cost of $73.50.

Dividing this sum by 89,300 tons gives a cost per ton of $0.0008 or $\frac{8}{10}$ of one mill. This is about $\frac{1}{4}$ of 3 mills, which was the cost per ton of braided cables given by C. E. Rogers in the excellent paper[1] of his committee on gathering locomotives.

*Part of a discussion of a report of the Committee on "All-Rubber-Insulated as Compared with Ordinary Braid-Covered Cables for Portable Entrance Locomotive Cable and Mining-Machine Cable" presented at the West Virginia-Kentucky Association of Mine Mechanical and Electrical Engineers. This report may be found in this issue of Coal Age.

Rubber-Covered Vs. Braided Cable for Mine Work*

Beware of Short Cotton Fiber in Braid—Kink Test—Though Rubber Covered Cable Lasts 75 to 100 Per Cent Longer, Mines Getting Ten Months' Service Out of Braided Cable Should Not Abandon It

ONLY such cables will be considered in this article as are used for connecting conductor-cable-reel gathering locomotives, coal-cutting machines, loading machines, portable lamp cords and other mining equipment to trolley wires. Until recently rubber-covered cotton-braided cable was in general use. Approximately two years ago all-rubber-insulated cable made its appearance, and for mining service it quite largely has replaced cotton-braided cable.

For a long time the question as to the kind of cable to be employed usually was left to the discretion of the salesman. The order called merely for No. 3 or No. 4 locomotive or mining-machine cable, as the case might be, and the conductor thus loosely specified often gave unsatisfactory service. In some cases the cable lasted only two or three months and sometimes an even shorter period, whereas the average life should be from six to eight months.

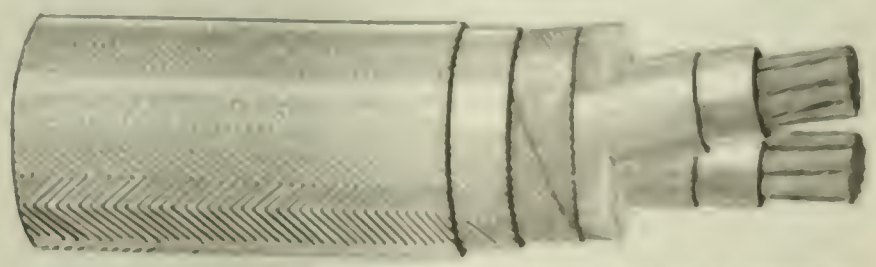
All cables of the braided type have a rubber insulation and a woven covering of cotton, either single, double or triple braided. This braiding is saturated with an insulating compound, the purpose of which is to keep water out of the cotton, thus preventing the fiber from loosening or rotting. It also gives to the cable a certain degree of slickness which helps it to resist abrasion. The chairman of this committee has made extensive tests on different forms of this type of cable and has found that some manufacturers use an inferior grade of cotton in their braid. The fibers are short and hard, and the life of cable of this kind is, of course, not as long as it should be.

Beware of Cable Compounds That Peel Off

The braid in some cable is not fully saturated with compound. Other cables show a beautiful glossy surface, giving the appearance of having plenty of impregnating materials, but the compound will chip off when the cable is bent. Consequently the braid becomes bare and presents a dull and ragged appearance. When this type of cable is used on gathering motors or mining machines the cotton braiding soon breaks and unravels and much tape is necessary to keep the conductor in service until at last so many splices have been used that renewal becomes necessary.

The chairman of this committee has had manufacturers submit samples of different makes of cables to which he has applied various tests in order to ascertain the strength of the cotton braid and rubber insulation. Among others he has used a "kink" test, in which the cable is bent into a short loop and then pulled out straight again.

None of the cables with ordinary woven braid would resist this test, as the insulation would tear under the stress. Most of the cables where the covering was of cord construction would come through the test in good condition. Some of the manufacturers are insulating their cables with heavier rubber than is found on ordinary braided cable, and when they do so the cable gives better service than any of the other cotton-covered cables.

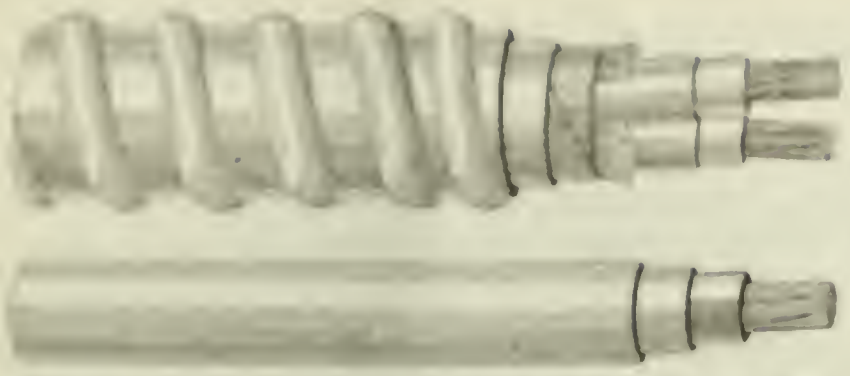


In making a choice between all-rubber-covered cable and braided cable, attention should be paid to the fact that all-rubber-covered cable costs from 75 to 150 per cent more than cotton-braided cables with the braiding of either weave or cord construction. Therefore, a cable with all-rubber insulation should have at least twice the life of ordinary braided cable.

For any mine which is getting from 8 to 10 months of service out of ordinary cotton-covered cables a change to all-rubber-covered cable is not advisable. The life of a cable as used on gathering reels on mine locomotives or loading machines, etc., usually ends when an excessive number of splices has been made, and it has been observed that a cable which with very careful handling would have only three splices after 8 months in service, would require, after that time with the same careful handling, to be spliced not less than once a week. After 10 months' service it would need splicing so frequently that to avoid loss of time it would be advisable to install new cable.

Number of Reelings Determines Life

It is apparent, therefore, that the life of the insulation and of the copper itself is limited by the number of times the cable has been reeled, especially if it is subjected to long hauls and is bent around sharp corners. Another factor which enters into the life of the cable is the voltage which is maintained at the entries on which the equipment is working. If the voltage is not kept within a reasonable range of the normal rating of the machine the cables are subjected to heavy currents and consequently to heating. This is likely to make the copper brittle. Furthermore, if the cable gets too hot so that the insulation warms up, the rubber separates from the copper strands, and on braided cable the insulating compound also melts out.



The life of cables subject to such treatment is very short, but under such conditions life proportional to value cannot be obtained from either type of cable. Another factor entering into the life of such conductors, especially on gathering locomotives, is the type of reel in use. At this point I would call the attention of manufacturers of gathering locomotives to the fact that

BRAIDED CABLE WITH TWO STRANDED CONDUCTORS

This cable has each conductor separately covered with rubber and braid, the two conductors with their covering being twisted. Jute fillers give the whole a circular cross-section. The cable thus rendered round is covered with tape and one or more interwoven braids.

*Report of Committee on "All-Rubber Insulated as Compared with Ordinary Braid-Covered Cables for Portable Extensions, Locomotive Cable and Mining-Machine Cable," presented at the Huntington meeting of the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, Sept. 21. Committee consists of F. M. Reigher (chairman), H. H. Pickrell and E. S. Stickel.

while they have made wonderful progress in the development of the reel type of gathering locomotives, the development of the reel itself has not kept step, and the cable reel is a subject which should have further consideration from the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers.

On some locomotives the spooling device will not accommodate No. 2 cables even when properly spooled, and in consequence toward the end of the spooling the cable is wedged and crossed on the reel. This injures the insulation and the stranding of the cables just as it injures the strands of a hoist rope when it is not wound properly or evenly.

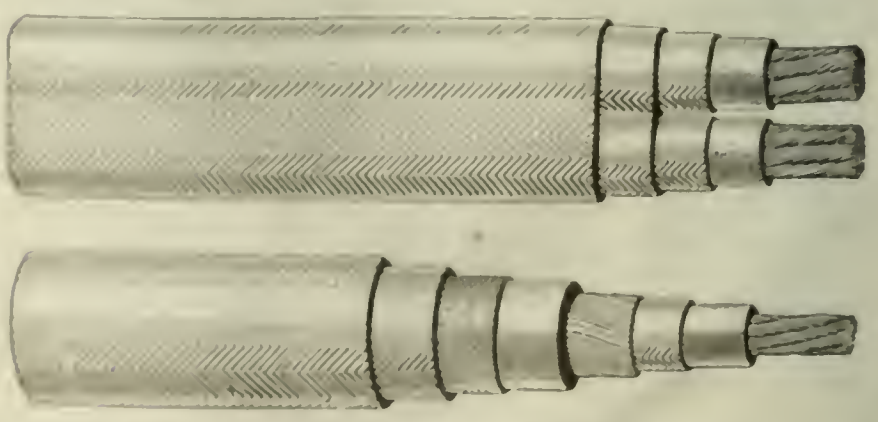
The manner in which the cable is handled by the motorman when gathering has much to do with the length of its life, as the men often get too much slack and then run over the cable and jerk or whip it. This is done when the men are either not familiar with the type of reel in use or are not cautioned as to the proper operation of the reels. It also occurs on some types of reels if the clutch has not been set at the proper tension.

The main fault in the types of all-rubber-covered cable now in general use is that the insulation stands up very well. After the cable has been run over or kinked severely the copper strands will part when subjected to strain, yet the rubber insulation will show almost no sign of injury. To find such a place in a 500-ft. cable will consume from one to three hours of a man's time. If he found it in less time he would be fortunate indeed!

When such gathering locomotive is required to haul a certain quota of cars every day, the motorman cannot reach this quota if he is delayed by an ineffectual search for breaks in his cable. The men at the Stonega plant for this reason look with a dislike to all-rubber-covered cable that at one time a braid over one was found all chopped to pieces. For this reason the claim that all-rubber-covered cable reduces frequent and expensive interruptions cannot be substantiated. It will seldom take a motorman more than 10 minutes to find and repair a break in braided cable. For this reason the Stonega Coal & Coke Co. has hesitated to accept all-rubber-covered cables as standard in its various operations. Another reason for not standardizing on this cable is that the Stonega Coal & Coke Co. is getting an average life of 6 to 10 months out of cord-braided cables.

At the last convention and industrial mining exposition the chairman of this committee told some of the representatives of the cable manufacturers that cable of No. 3 conductivity and cost was wanted with the tensile strength of No. 2 and cable of No. 4 conductivity and cost with the tensile strength of No. 3. To obtain this I recommended the use of a steel or similar reinforcement of high tensile strength.

Some of the manufacturers of all-rubber-covered cable are following this suggestion and have brought out during the last two months different types of reinforced locomotive cable. At the present time a cable of this type has been in service approximately two months and the results obtained are quite satisfactory. The Stonega Coal & Coke Co. will receive in the near future cables of various kinds all thus reinforced and will continue its experiments on this type of cable.



For extension cords around mines and mine shops all-rubber-covered cable should be used. The wire should be of not less than No. 14 gage, for the majority of electricians break or injure the fine strands when skinning the wires and thus reduce the carrying capacity of the cable and its ability to withstand the pulls and strains to which extension cords are subjected.

The committee would suggest to the manufacturers rubber-insulated cable from No. 4 to No. 1 gage should have 133 wires. For ordinary braided cable up to No. 3 size the limit should be set at 49 wires, as the danger of puncturing the rubber insulation with the finer sizes of stranding would be too great. For the larger sizes No. 2 and No. 1, 133-wire cable is necessary to insure flexibility. On the cables where the braiding is of cord, the strands for No. 3 can contain either 133 or 49 wires. Not more than 49 wires should be used, however, in No. 4 cable.

The committee would suggest to the manufacturers of all-rubber-covered cable that they reduce the cost of their cables so that they will come closer in line with the cotton-braided cables, as it believes that in many cases the additional service obtained from the all-rubber-covered cable over the braided cable does not warrant from the 75 to 150 per cent higher cost.

It believes that all-rubber-covered cable is a step forward to a better insulated and more serviceable cable and would like to see wires and cables of this and similar construction manufactured for installation work, as it believes that it will give excellent service in conduit, where the cable is subjected to much vibration, as in tipples and breakers. It also thinks that fire hazards will be greatly reduced by the use of this type of cable, as rubber is not as easily ignited as a cotton weave saturated with compound which is at present used to insulate wires and cables for installation work.

Though this paper does not mention the multiple-conductor mining-machine cables, attention is called to the fact that all that has been said in regard to the insulating and wearing properties of the cable as used

TWIN MINING-MACHINE AND CONCENTRIC DUPLEX CABLE

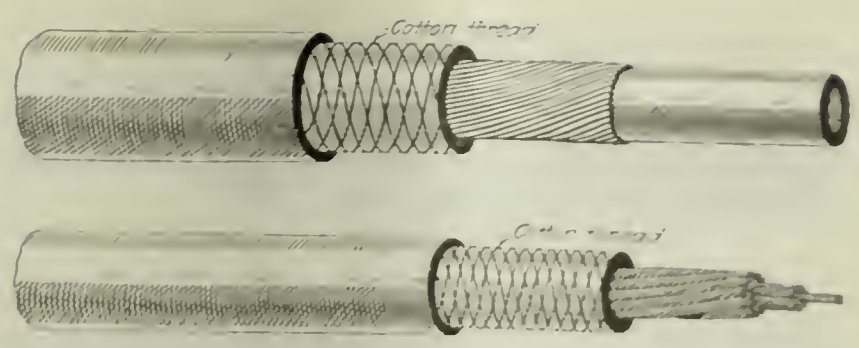
The twin cable is flat and made up of two stranded tinned conductors each insulated with rubber and one weatherproof braid. These are laid up parallel. Over them are wound two or three weatherproof braids.

by gathering locomotives applies also to this cable. There remains the question whether to use concentric or twin cables, but the opinion of all who use cable for this purpose is so greatly divided that no conclusive arguments can be brought forward to decide the question, because, after all has been said, each one uses the type of cable, concentric or twin, that meets his own peculiar conditions best.

Engineers Detail Experience with Machine Cable, Resistors and Insulating Oils*

AT THE third session of the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, on Thursday, Sept. 21, F. M. Reigher, of the American Coal Co. of Alleghany County, Bluefield, W. Va., made the report for the committee on cables. Mr. Reigher proved a firm advocate of braid-covered cables, not so much on the ground that they were better than rubber-covered cables, which he did not claim, but because the latter were more expensive and would have to be cheaper to receive his indorsement. He asserted that the wires inside a rubber-covered cable were likely to break, and when they did it was sometimes extremely difficult to ascertain just where the defect occurred.

Reuben Lee, of the Elkhorn Piney Coal Mining Co., Stanaford, W. Va., said that cars could be run over rubber-covered cable without any trouble of the kind described. He himself would use nothing else. His company had used that type of cable for seven or eight years. N. A. Johnson, of the Buffalo-Eagle Coal Co., Braeholm, W. Va., declared that he had no trouble with concealed broken wires. At his mine he had never been able to get, like Mr. Reigher, seven or eight months of service out of braid-covered cable. He preferred an all-rubber coating. He found difficulty in holding enough cable of adequate size on certain types of reels.



C. E. Rogers was afraid that the rubber of rubber-covered cable would deteriorate before he would get sufficient life out of it to justify its greater expense. He found that foremen and superintendents were quite willing to pay the greater cost if thereby they could get better service out of the cable, certainty in operation being in their belief more important than ultimate length of life. Mr. Johnson said that the saving in splicing reduced delay and justified the higher cost.

Deterioration Vs. Wear Factor in Cable Life

Mr. Reigher stated that in estimating the life of a cable consideration should be given not merely to days of life but to the number of reelings and unreelings during that period. Some men reeled out the cable twice as many times a day as other men, thus inevitably shortening the life by increasing the daily service. A. Fred Phelps, of the Post Glover Electric Co., said that rubber-covered cable would last two or three times as long as cable covered with braid, but nevertheless it might not last ten months where the conditions of service were peculiarly trying.

Mr. Reigher urged that 133-wire cable was made up of excessively small wires and said that such wires punctured the covering. He believed that rubber-covered cables with steel reinforcement in the rubber could be guaranteed for twelve months. He could not see that rubber-covered cable could be expected to last long

*Conclusion of report of meeting at Huntington of the West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers. See also issues of Sept. 28 and Oct. 5.

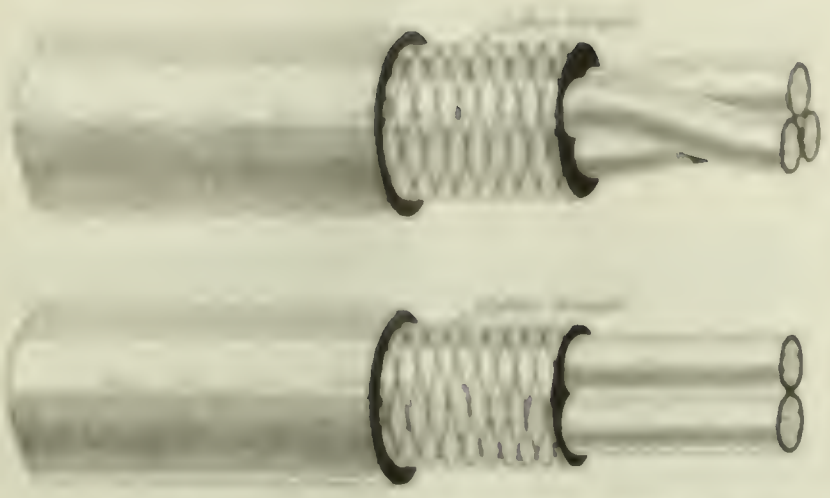
TWO TYPES OF ALL-RUBBER INSULATED CABLES

The top cable is a concentric duplex cable with rubber between the two conductors. Around the outer conductor is a covering of rubber, on which two cotton strands are wound in opposite directions. This is covered again with a coating of rubber. In the lower illustration is a single conductor with a covering similar to that of the outer conductor in the duplex cable above.

enough to make the investment profitable. Mr. Phelps said that no guarantee of the life of a cable should ever be given because a "short" might at any time overheat the wires and insulation. Furthermore at some places cables would last eighteen months and at others not more than thirty days.

H. M. McFarland, of the Simplex Wire & Cable Co., said that much depended on how the strands were disposed. He found seven and nineteen strands better than nineteen and seven. Mr. Reigher remarked that he was opposed to the use of such fine stranding for a No. 4 cable, whatever might be used in those that were larger. Mr. Phelps amplified his previous statement by saying that the compensation rules in Pennsylvania made favorable insurance provisions wherever fuses were provided in the cable. One objected, however, that fuses were useless, as machine men would take ample care that the fuse was provided with a conductor that would not fuse at any lower current than that which would melt the wire in the cable. For this reason fuses would be little or no protection.

Cable Larger Than No. 4 to Have 133 Wires



E. S. Simkins, of the Standard Underground Cable Co., declared that the whole matter had been discussed at a hearing held by the Bureau of Mines and it had been decided that 133-wire cable should be used for the larger cables but that No. 4 and smaller should have only 49 wires.

Mr. Lee said that the grades at Stanaford were so heavy that the cables heated and the rubber came off on the braid-covered cable. Someone remarked that the insulation in braided cable varied greatly and some specification should be made as to the amount of rubber used. Mr. Simkins said that every kind of insulation was used by unscrupulous manufacturers. Some of it, he jokingly asserted, was a mixture of Jersey mud and molasses.

He said that when reeled in three layers cables had only about one-half their unreeled capacity. The mine locomotive builders admitted that their reels were too small for an adequate size and length of cable, but with that admission they rested. They had done nothing to increase the size of their reels.

Roscoe Woltz, for the committee on the use on mine locomotives of resistance grids made of rolled steel plate as compared with cast grids, made a report on that subject, as published in the issue of *Coal Age* of Sept. 14. Mr. Reigher declared himself a believer in the steel grid. Nevertheless he said he had cast grids in use that had lasted six years.

Mr. Phelps said that the steel grids would occupy no more space than cast grids and that standard grids

could be so assembled as to fit whether the space was narrow or wide. The grids for the first point were assembled with spaces of ¼ in. On the last point the spacing was increased to from ½ to ¾ in. apart. It was always a surprise to him how little experimental knowledge there was about the design of grids. His company was experimenting, but there was still much more to be learned.

He said that the 4 per cent silicon-steel grids rusted on the surface, but the rust formed a protective coating, preventing any further deterioration. George Suiter, of the Wheeling Coal Co., a member of the committee, volunteered an indorsement of Mr. Phelps' statement that a steel grid was just as readily repaired as one of cast resistors. He had eighteen out of thirty mine locomotives and several mining machines fitted with steel grids and he had no difficulty in repairing them.

In the enforced absence of W. C. Shunk, general superintendent of the Sturgeon Coal & Coke Co., R. Dawson Hall read Mr. Shunk's paper on "How Mechanical and Electrical Men Can Increase Their Usefulness and Therefore Become More Important Figures in the Organization." In discussing the paper J. H. Edwards, the president, electrical engineer for the Elkhorn Piney Coal Mining Co. and other companies, declared that electrical engineers need more system so that they can the more readily tabulate experience and costs. He declared that a little clerical experience was an asset to any electrical engineer. A. B. Holcomb, of the Corbin Caffrey Co., remarked that it had been stated at a meeting of steel engineers that with maintenance cost sheets it was often possible to show that a machine that was giving excellent service might profitably be scrapped with a saving in upkeep expense sufficient to pay for the new machine in two or three years to the company which then dispensed with it.

On Friday, Sept. 22, a paper was read by M. W. Crenshaw, of the wireless department of the Banks Supply Co., of Huntington, W. Va., on "The Wireless Telephone." A. F. Brosky made some brief remarks about the experiments carried on by the United States Bureau of Mines and the Westinghouse Manufacturing Co. in a mine near Pittsburgh. It was found that the rock intercepts the waves at depths exceeding 50 ft. and that the receiving instruments that gave the best results on surface work were not as successful underground as others that were regarded under ordinary conditions as being less desirable.

R. R. Webster, chairman of the committee on the "Proper Handling and Care of Insulating Oils," read the report on that subject. This report appeared in *Coal Age* in the issue of Sept. 28. The chairman said that the subject was one of considerable importance, as many transformers had been in use now for quite a few years and the oil had not been changed or filtered. He also read the following statement:

"The following are tests on the oil of three General Electric 65-kva. 2,300 206-volt single-phase transformers, used inside a mine substation to supply a synchronous converter. The two tests are about two years apart, the oil not being filtered or renewed in the meantime. The day load on these transformers has been averaging approximately 60 per cent of full load. However, the short-time peak loads often exceed 175 per cent of full load. A temperature test taken during the summer, when these transformers were reported to be running warm, showed the oil to be 114 deg. F. Note that the decrease in the dielectric strength of the oil during the two years is considerable:

Transformer Serial Number	Test Sept. 25, 1920 Oil From Bottom	Oil From Top	Test Aug. 28, 1922 All Oil Samples From Top Sample 1 No. 1	Sample 2 No. 2	Dielectric Strength In Percentage Of First Test
1,573,264	14,250	18,000	13,000	13,500	73.5
1,573,280	19,000	23,000	16,000	12,000	61
1,573,263	....	10,500	10,500	....	100

NOTE: The laboratory which made the test of Aug. 28, 1922, reported no sludge in oil, described the color as "lemon" and recommended "filtering for moisture."

"The following is quoted from an article by J. L. R. Hayden and W. N. Eddy which appeared in the July, 1922, issue of the *Journal of the American Institute of Electrical Engineers*. It is a tabulation of the average per cent error that might be expected for (1) a single test, (2) three tests, or (3) six tests on oil if the mean of 500 successive breakdowns is taken as the correct dielectric strength and any variation from that as the error.

	Air	Long Sphere Gap In Oil Per Cent	Short Sphere Gap In Oil Per Cent	Needle Sphere Gap In Oil Per Cent
Single breakdown test				
Average error	1 1	7 8	7 8	8 4
Maximum error	6 7	48 5	34 1	44 8
Maximum error except 3 readings	4 0	33 0	31 8	35 0
Three breakdown tests				
Average error	0 8	5 2	4 9	4 9
Maximum error	4 0	22 4	19 7	19.1
Six breakdown tests				
Average error	0 6	2 7	3 5	4 1
Maximum error	2 9	17 5	15 0	14.3

Mr. Crenshaw wanted to know how the "sweating" properties of a steel transformer differed from those of one made of cast iron. He was told that a transformer case if properly prepared by drying for the reception of the oil would not permit of an accumulation of sweat, providing the oil itself was free from moisture.

It being learned that the Coal and Industrial Exposition would not be held in Huntington next year, the association concluded not to set any place for the next meeting until it was ascertained where the exposition would be held.

THE U. S. BUREAU OF MINES does not make life tests of batteries used on electric lamps, but the performance of the batteries is studied during a short period while the lamp bulbs are being tested for life and uniformity. Also, field inspections are make by the bureau's electrical engineer, and reports are obtained from both users and lamp manufacturers. As a result of this general information the bureau believes that lead cells will give 300 shifts of 12 hours each, and alkaline cells 600 such shifts, without plate renewals.

Ventilation of Mines with Flexible Conduits

Brattice Cloth, Sollars, Windboxes, Metal and Flexible Pipe as Means of Ventilating Blind Entries—Method of Suspending and Coupling Pipe and Erecting Ventilating Machinery

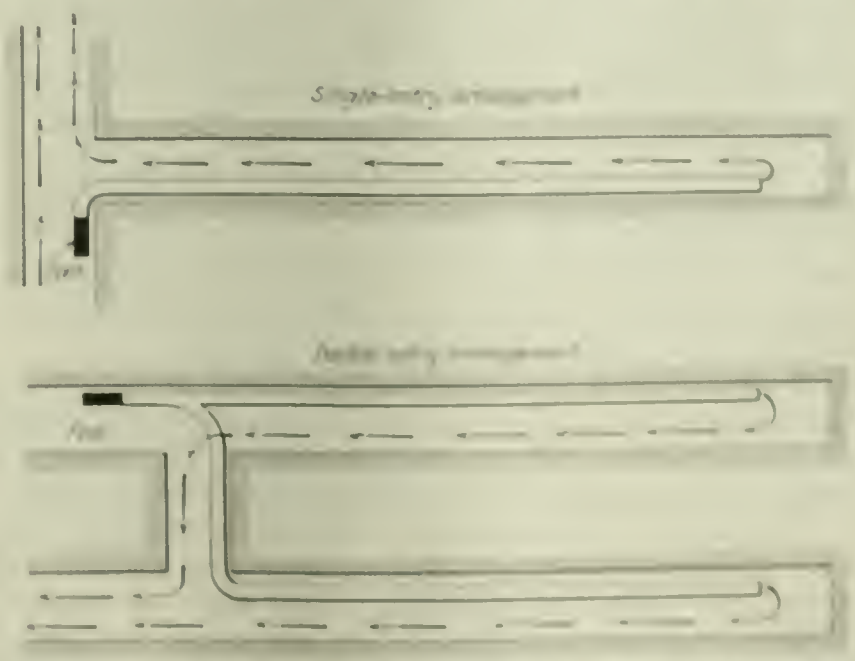
EVERY coal mine requires some sort of ventilation. As a rule the circulation of air through the various headings and rooms of ordinary workings is not difficult, as every mine is, or should be, laid out with this end in view. When it becomes necessary, however, to ventilate long stretches of single heading or various other dead-end operations a more serious problem is introduced.

Common means of carrying air to dead-end faces include the brattice, the sollar, the windbox, and various kinds of pipe, either rigid or flexible. The brattice is well known to all coal miners. It consists of a partition built up of boards or canvas, or both, extending throughout the length of the place to be ventilated, dividing it longitudinally into two sections or compartments. In one of these the air travels inward and in the other outward.

A large volume of air may be handled by the brattice. It is nevertheless subject to may shortcomings. In the first place it is always liable to more or less leakage. The brattice itself as well as the joints at floor and roof seldom can be made tight. If carried to a point near the face it is subject to injury from shooting. This is particularly true if the passage to be ventilated is in rock which must be blasted from the solid, this of course necessitating heavy loading. It also reduces the width of the roadway unless the place driven is specially widened for that purpose.

Dividing the Airway by Horizontal Brattice

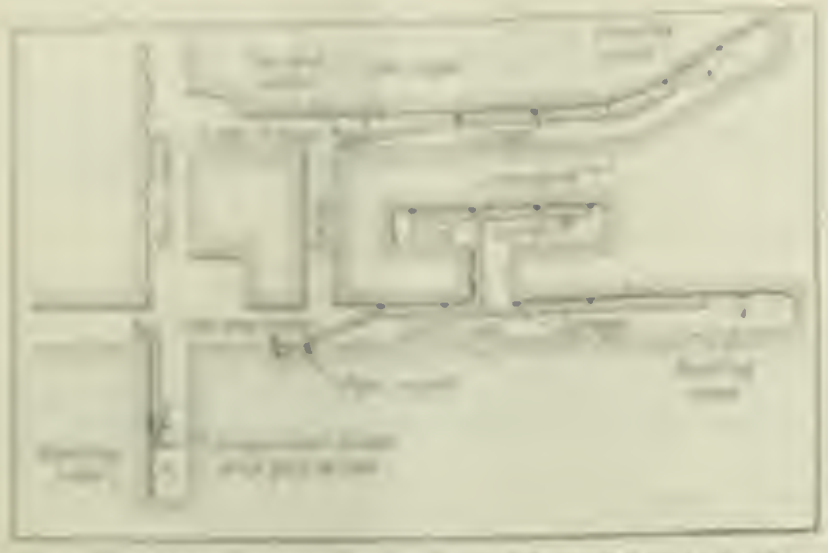
Sollaring air to the face as a rule is more expensive and less satisfactory than bratticing. Whereas the brattice divides the heading or driven passage vertically the sollar divides it horizontally. Thus a bratticed heading contains two compartments side by side, while the sollared heading has two passages one above the other. The sollar has all the shortcomings of the brattice so far as leakage is concerned with the added disadvantage that it is applicable ordinarily only where timber framing such as post sets are used.



The windbox is a modification of the sollar. Here air is carried into a working by means of a wooden box laid, usually, on the floor at the side of the driven passage. Such a box, even though effective, is difficult to make airtight and requires much lumber, as a rule being made of tongued-and-grooved flooring. It also adds appreciably to the fire hazard and is not an efficient means of carrying air, as the frictional resistance is considerable.

Sheet-iron pipe often is used to convey air to the remote faces of headings and rooms. This may be either black or galvanized and usually ranges from 8 to 24 in. in diameter. Though fairly tight and losing much less air from leakage than any of the devices previously mentioned, it is somewhat difficult to handle, as it cannot be collapsed in any way. The maximum length that can be transported conveniently is about 10 ft., so that many joints have to be made in its erection. In addition to all this the sheets from which such pipe is made are thin and subject to rapid corrosion. Galvanizing will protect them from water but not from acid, which many, if not most, mine waters carry in solution. Consequently such pipes, though affording excellent results for a time, are as a rule short-lived. Another disadvantage of such pipe is that it becomes dented, causing a loss in carrying capacity, and if this occurs near the joints the leakage is considerable.

During recent years another form of piping that possesses many advantages over the devices previously mentioned has come into more or less extensive use. This is a tube of canvas or fabric that is marketed under various trade names. Such tubing is manufactured by at least three makers—two in this country and one in England. Thus the Bemis Bro. Bag Co., of St Louis, Mo., manufactures a canvas tube known as Flexoid; E. I. du Pont de Nemours & Co., Inc., of Wilmington, Del., makes a fabric tube similar in many respects to the product just mentioned but known as Ventube, and the Telephos Co., Ltd., of Vaughan Road, West Harrow, Middlesex, England, manufactures a canvas pipe known as Ventwal.



All the tubes manufactured by the above firms are circular or elliptical in cross-section. An Australian device of similar nature is made with a rectangular section. Inasmuch, however, as this shape does not lend itself readily to manufacture at low cost and as a conduit of this section must be supported by a framework of light wood or metal this device has not met with extensive application. The circular forms also oppose less resistance to the air current.

In ventilation by means of flexible conduit the joint between sections has always presented difficulties. In the Flexoid and Ventube pipes this has been overcome by fastening a light spring-steel slightly collapsible ring at either end of each section of tubing. In joining two sections together one of the end rings is slightly

METHOD OF USING FLEXIBLE PIPE IN SINGLE AND DOUBLE ENTRY

With these arrangements liberal ventilation can be afforded the faces of entries, thus driving out gas and smoke. At the time workmen are waiting for the clearing away of the bad air from a single shot a line of flexible conduit could be hung from the crosscut to the face, making bad air unnecessary.

DIFFICULT PROBLEMS IN VENTILATION BY STEEL TUBE

rolled and pushed sidewise through the ring on the other section. It is then turned so that it is parallel with the mating ring and the two section ends pulled from each other until the joint is made tight.

In the Ventubal tube a slightly oval steel ring is sewed into the end of each section or length of pipe. When in proper position the end of one tube may be readily inserted within the end of the other. Then turning one tube or section through an angle of 90 deg. and pulling the joint tight locks the two ends securely and makes a junction that is practically airtight.

How to Hang Where Cars Cannot Injure It

To assemble any of the above joints the sequence of operations is merely reversed. In any case no tools are required, neither is any particular skill necessary. Any ordinary workman can soon learn to make or break joints with ease and precision.

One great advantage enjoyed by tubes of this kind is the ease with which they can be disposed within a mine passage whether this be driven in rock or coal. In most instances such tubing is suspended at the side of the heading or room and near the roof and in this position it does not interfere with haulage. Messenger wire is first strung and drawn taut. The method of suspending this wire will depend on conditions. If the passage is timbered this wire may be stapled to the roof beams every 12 to 15 ft. If such roof beams are not available, sprags may be wedged between the ribs near the roof or, if the roof is irregular and arched, between irregularities occurring in the roof.

If the room is wide and the roof level or flat, holes may be drilled in the rib into which short iron rods may be inserted. These should project out from the rib a distance equal to at least one-half the diameter of the canvas tube, and upon them the messenger wire may be hung. Wooden rods may be placed in such rib holes, to which the messenger wire may be stapled. Cross-pieces may be nailed between posts, to which the wire may be attached, or short pieces of boards may be nailed to the posts, extending out to one side a sufficient distance to permit the tube to hang free. In any case, suspension of the messenger wire is comparatively easy. Another method is to set plugs in the roof and hang the messenger wire from these. No. 8 B. & S. galvanized wire is recommended.

Attachment of the tubing to the messenger wire is made by means of hooks spaced at about 2½ ft. intervals. In shafts, winzes or raises suspension collars are placed on the tubing every 50 to 100 ft., depending upon its size and consequent weight. These are fastened by means of wires to the side walls or timbering so as to take all the weight of the tube section to which the suspension collar is attached. Excessive weight upon any joint or coupling is thus avoided.

The manufacturers of Ventube claim for their fabric a chemical stability that enables it to resist the acid and gaseous conditions encountered underground, as well as attack from fungous growths of various kinds. It is also waterproof and of great toughness and tensile strength, as proved by an eighteen months' test in mines where the conditions were unusually severe. The stitching of the tubes is made with specially treated thread.

Tube Can Be Patched Like a Rubber Tire

A special cement is used for patching, the part to be patched being deflated and the torn section to be covered being carefully cleaned with gasoline. Two coats of cement are placed on the pipe and on the patch and left to dry. When completely dry the cemented portions are hammered together on a flat surface, giving instant adhesion. For temporary repair underground a small patch can be sewed on, and this usually will give entire satisfaction.

"Fittings" for this kind of tubing are exactly analogous to those available for wrought-iron or steel pipe. They include elbows, tees, wyes, reducers and the like as well as a connection to join the tube to the rectangular discharge nozzle of a fan or blower. A blasting piece also is sometimes used next to the face if heavy charges are to be fired. This is drawn back before the shots are detonated, and pulled forward again after the blast, thus avoiding the injury to the fabric which frequent removal and dragging over the ground would inevitably cause should the end tube be unhooked every time before a shot was fired.

As a rule a fan or blower will be used to furnish the air current. Where compressed air is available, however, a small jet may be led within the outbye opening of the pipe and a ventilating current induced on the principle of the injector. Tests made in South Africa some years ago showed that 5 cu.ft. of free air per minute escaping under pressure from a ⅛-in. nozzle opening induced a current of 210 cu.ft. per minute; 80 cu.ft. of free air escaping under pressure from a ¼-in. opening actuated a current which delivered 1,080 cu.ft. of air. These experiments were conducted on a 538-ft. length of 9-in. pipe, and the figures on the resulting current just given were the discharges measured at the outlet opening and included, of course, the input of compressed air.

In most cases, however, as above stated, a fan or blower will be employed. This may be mounted either permanently or temporarily. For a permanent foundation no material, all things considered, appears to equal concrete. Brick or stone masonry may, however, be employed to advantage. In emergencies or in cases where the fan and tubing are to be used for only a short time a wooden foundation may be employed. This can be built up of mud sills and cross-pieces, bolted, drift-bolted or spiked together. Any timber that is

convenient, such as posts, ties, chock lumber and the like may be used, provided an even foundation surface is secured. Sawn lumber, of course, is preferable. If properly made a fan may be operated on a foundation of this kind for a long time.

In work of this nature the motor and fan, if possible, should be direct-connected. If this is done both elements may be bolted on a common base, which in turn is bolted to the foundation as a unit. For large volumes of air, however, belt or chain drives have their advantages, as the motor and fan may then be readily separated and moved into place with greater ease than if joined rigidly together. This arrangement, however, necessitates two foundations. Many companies manufacture fans suitable for this kind of work. Many motors also are available.

Although ventilation by this means will hardly be used in the ordinary operation of a well-regulated coal mine it may advantageously be resorted to for special work or in time of emergency. Thus it will find application in driving long passages, such as drifts or slopes from one bed to another, under streams and the like. The accompanying illustration shows some of the dead-end faces that can be ventilated by this means.

So far as coal mining is concerned it is in time of emergency that this type of ventilating equipment will be found most valuable. Its light weight—one man can carry 100 ft. of 16-in. tubing without serious inconvenience—and the rapidity and ease with which it may be erected are considerations of high value after a disaster, such, for instance, as an explosion. Furthermore, in fighting mine fires it may in many cases be used to good effect. This will be particularly true in those instances where the exact location of the fire is unknown and where it is desired to attack it from above. Under such circumstances sometimes thousands of feet of narrow passages must be driven. As every mining man knows, these are extremely difficult, if not impossible, to ventilate by ordinary means.

In such emergencies also time is, or may be, an all-important element. No man can do his best in an atmosphere depleted of its oxygen or vitiated by smoke or explosive fumes. Pure air in adequate volume delivered at or close to the working face will not only promptly clear away powder smoke and the like but will assure a maximum of effort from the workmen employed. With an outfit of this kind such an emergency can be met without delay.

Reports and Investigations State Geological Surveys and Mining Bureaus

Coal Reserves of Cambria County, Pa.

By John F. Reese

CAMBRIA County, Pennsylvania, has six coal beds that are now of economic interest. In order of their present importance as shipping coals these are the Lower Kittanning, Upper Kittanning, Lower Freeport, Upper Freeport, Clarion and Brookville.

The many mines working the Lower Kittanning bed and exposures of its outcrop have furnished many measurements of its thickness, thus making possible an accurate and reliable computation of the quantity of coal contained. The "B-Rider" coal of the Bens Creek area has been computed along with the Lower Kittanning coal in this report.

The Lower Kittanning is the most persistent bed, contains the greatest coal reserve and is the largest producer within the county, yielding more than 8,100,000 tons annually.

A fair amount of information as to the thickness and persistency of the Upper Kittanning bed is available. This measure is best suited for mining in the Patton, Portage, South Fork and Johnstown areas.

A fairly accurate estimate of the quantity of coal in the Lower Freeport bed is made possible by many measurements at mines and outcrop. This measure attains its best development for mining in the Barnesboro-Spangler area.

The extensive outcrop of the Upper Freeport bed throughout the county, and its mine development in various localities, furnish a fair number of measurements for an accurate estimate of its quantity. It is mined most extensively in the Barnesboro, Hastings, Gallitzin and Cresson areas, where it attains its best thickness.

The Clarion or A coal has been computed as of economic interest in Reade and Richland townships, where it has been mined. Little is known of its thickness and extent, and only areas surrounding mining developments or proven ground have been computed.

The Brookville or A coal bed has been considered as of interest in five townships, namely, Adams, Cresson, Dean, Gallitzin and Richland. Only areas surrounding operations or proven ground have been computed, as little is known of the extent and persistency of this coal.

Cambria County has a total area of 697.4 square miles. The result of computing the coal reserves in this county based on the latest maps, engineering data, and methods is shown in the accompanying table. The figures are here given as computed. It should, however, be distinctly understood that while the acreage of each of the beds has been accurately calculated, the reliability of the average thickness of the coals employed in the computation of tonnage decreases for the various beds in the order following: Lower Kittanning, Upper Freeport, Lower Freeport, Upper Kittanning, Brookville and Clarion. Thus, while the figures for the Lower Kittanning bed are conservative and probably reliable, those for the Clarion coal may be much too small or many times too large.

Detailed tables of the coal reserves in each township have been prepared and will appear in printed form in a report now being written on the bituminous-coal fields of the state. They can be consulted in the office of the Topographic and Geological Survey; or figures for a single township will be mailed from that office on request.

COAL RESERVES IN CAMBRIA COUNTY

(In Net Tons)

Bed	Original Deposit	Mined Out	Recoverable
Upper Freeport	1,016	14	715
Lower Freeport	1,337	85	1,252
Upper Kittanning	922	80	842
Lower Kittanning	2,616	271	1,344
Clarion	32	1	31
Brookville	64	(13)	61
Total	5,183	458	4,239

Valuation of Coal Land Leaseholds In Tax Returns

By W. R. Ross
[illegible]

IN EVERY coal field there are operations on leased land. Many companies mine both from leaseholds and from land owned in fee, but not all of those who work under leaseholds appreciate the value of the lease or realize that they are entitled to establish on their books and before the Income Tax Bureau a proper value for this form of property. In particular those operators who had substantial earnings prior to March 1, 1913, or who have preferential royalty rates or favorable conditions are in position to profit by taking advantage of this feature of the tax law and regulations.

Under the revenue acts of 1918 and subsequent years the value of a lease may be amortized. The procedure is comparatively simple. The Treasury Department has a Form R, rather formidable it is true, but one that most companies find it necessary to file. The facts necessary for a basis to establish the value of a leasehold are assembled when Form R has been filled out. But the Treasury Department does not make the deduction in tax that corresponds—the lessee must set up his claim.

Whatever value was vested in the ownership of any property on March 1, 1913,* must in the event of a subsequent sale of that property be recognized as capital, and is entitled to the return free from income tax, regardless of the fact that that value may have been in excess of its cost. Consequently revenue legislation has provided that profit in the sale of such assets shall be ascertained by taking the fair market value as of March 1, 1913, as the basis of value. Therefore, it has always been recognized that the taxable profit from the sale of a mining lease shall be its value in excess of the March 1, 1913, value. This being the case, the importance of establishing such values in the case of the sale of such property is obvious.

Supreme Court Ruling Awaited with Interest

It would have seemed natural for Congress to provide for deduction of depletion, or, more strictly speaking, for the amortization of such leasehold values as allowable deductions in ascertaining taxable income under the various revenue laws, but it was not until the passage of the act of 1918 that proper consideration was given to this situation and an allowance provided to the lessee. The Supreme Court has decided that under the 1916 law the lessee is not entitled to such a deduction. No doubt before long a specific ruling by the same body will also be had as to the status of such deductions under the law of 1917.

Full recognition of the rights of the lessee operator to recover his equity in such property by appropriate deductions for depletion based on cost or the value at March 1, 1913, was first given in the 1918 tax laws. Of course it was always in order that the actual cost of acquiring such a lease might be amortized, but the appreciation in value was not therefore recognized.

*The sixteenth amendment to the Constitution of the United States provides: "The Congress shall have power to lay and collect taxes on incomes, from whatever source derived, without apportionment among the several states and without regard to any census or enumeration." This amendment was ratified by a sufficient number of states by Feb. 25, 1913, to become its effective date for purposes of ascertaining leasehold values. March 1, 1913, is referred to in succeeding legislation as the date upon which the previous legislation of Congress in the matter became operative.

The Bureau of Internal Revenue has issued voluminous regulations as to how values may be established. They may be summarized as: cost; sales or transfers of similar properties; royalties and rentals; values for capital stock or local taxation; records of litigation; probate court inventories; disinterested appraisals, and present value of eventual earnings.

Because comparatively few representative transfers of operating coal-mining property took place around the basic date of valuation, March 1, 1913, and because the other methods offer little for comparative value most valuations in this field are determined by the present-value method. This method is one generally recommended by the engineering profession and is equitable in that it gives recognition to the value of management as a factor. Two properties may be of apparently similar nature, yet one be a failure and the other a success. As a former official of the Internal Revenue Bureau put it: "A dollar of capital which will earn a quarter is worth more than a dollar which will earn a nickel."

R. V. Norris Defines "Present Value"

A leasehold is a property right and to appraise its present value requires first a knowledge of the proper method and second certain basic facts. R. V. Norris' defines present value as follows: "The total value of a property at any date is the value of the future earnings of such property discounted to that date. The value of the mineral in the ground at any date is the total value of the property as above, less the value of the present and prospective expenditure for plant, development and equipment necessary to recover such mineral discounted to the same date."

The Treasury Department has held that taking into consideration the hazards of mining and marketing, a fair basis of valuation in the bituminous coal industry is obtained by using a discount factor of 8 per cent with a sinking fund provision of 4 per cent. Many engineers, however, will not agree with this basis.

Let us illustrate the theory of the valuation of a leasehold on the basis of earnings in the period prior to March 1, 1913. Assume that in the period prior to 1913 the average earnings† were 30c. per ton, that the life of the reserves after the date of valuation was twenty years and that the average annual production is 100,000 tons. This would give an annual profit of $30,000 and prospective profits in twenty years of $600,000. The present worth of the eventual earnings, $600,000, discounted on the basis of 8 per cent and invested in a sinking fund at 4 per cent is found, by using Hoskold's formula, to be $264,126. If from this is deducted the cost of plant, present and prospective, assumed here to be $125,000, we find the present value of the leasehold to be $139,136. On the basis of the 2,000,000 tons unmined at date of valuation, this gives 6.956c. per ton, which may be deducted as depletion. If the annual production is 100,000 tons we have $6,956 allowable deduction and therefore a decrease of that amount in the taxable income.

Using the 1918 income tax rate for corporations of 12 per cent, plus 65 per cent, the highest bracket of the

†"The Federal Income Tax," R. V. Norris, Columbia University Press, page 229.

‡The proper figure for average earnings here is obtained after deducting as "cost" the things defined by Article 206 of Income Tax Bureau Regulations 62, as those in connection with producing, preparing and marketing the mineral product sold, exclusive of federal income and profits taxes, allowable capital additions and provisions for depreciation and depletion, but including cost of repairs and replacements necessary to maintain the plant and equipment at its rated capacity and efficiency.

excess profits tax into which many of the coal companies rates ran, we have possible a 77 per cent tax. Taking 77 per cent of our $6,956 we have $5,556 as the maximum saving through proper valuation of leasehold. Of course if the earnings in the period before 1913 were higher than the assumed average of 30c. or if the life of the coal is less than twenty years the per ton value would be correspondingly higher and the saving greater; if lower, the reverse would be true.

If the lease have a preferential rate of royalty as compared with neighboring properties made under similar conditions and at approximately the same date, values may be assigned upon the basis of such preferential values, without the necessity of proving on the basis of earnings.

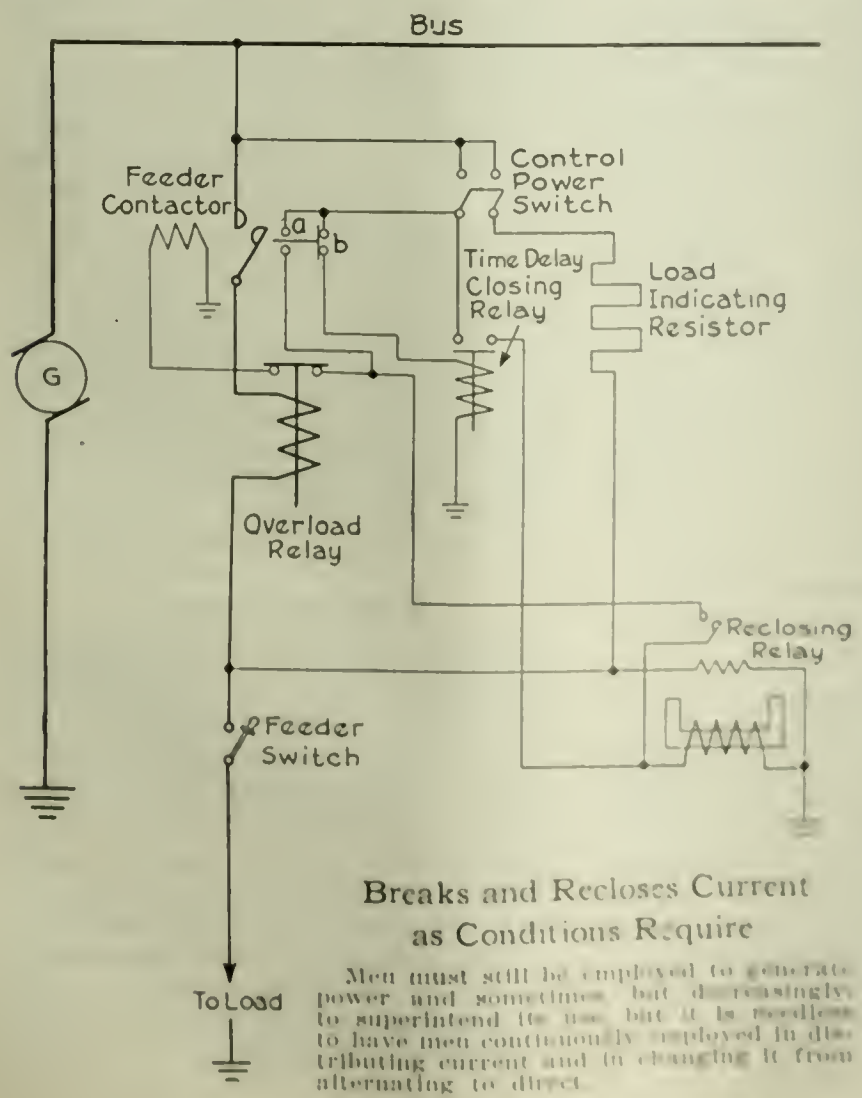
It is possible that at times a value may exist in a leasehold for the purpose of invested capital. These cases are the most difficult to establish, but if the lease was a proven tract and was turned over to a corporation in exchange for capital stock of the corporation, the value of the lease may be "paid in surplus" within the meaning of the law and be capitalized as such at its value at date of acquisition, subject to the limitations, for the year 1917, of the par value of the stock or shares specifically issued therefor.

Recloses Instantly Circuits Temporarily Short-Circuited or Overloaded

AUTOMATIC reclosing equipment for use on direct-current circuits of 300 and 500 volts has recently been designed and constructed. Its function is to protect apparatus in case feeders become short-circuited or overloaded, and at the same time to insure a continuity of service when the trouble is only temporary.

This equipment, which is constructed by the General Electric Co., is designed for use on circuits employing stub-end feed, a combination of stub-end and multiple feed, or in combination with a sectionalizing switch or sectionalized feeder.

The manner of its operation on a stub-end field—that is, one where the load is supplied by current from a single source—is so typical that once described the reader will have a clear idea of the manner in which the apparatus functions under other circumstances. The various devices that go to make up the equipment are a shunt contactor, an instantaneous overload relay, a reclosing relay, a control power switch and a load-indicating resistor. These devices are connected in accordance with the accompanying wiring diagram.



The sequence of operation of the equipment in case of a short-circuit or heavy overload on the feeder is as follows: The overload relay opens its contacts, thus de-energizing the coil of the contactor, which opens instantaneously, disconnecting the load from the power supply. When the contactor opens it closes the auxiliary switch (*b*; see diagram) which energizes the coil of the time-delay circuit-closing relay, which starts to close. The time delay is inserted at this point in the sequence in order to allow conditions on the feeder line to become stable. Closure of this relay completes the circuit through the lower coil of the reclosing relay.

Operates Somewhat Like a Voltmeter

The reclosing relay has two coils, both of which must be energized before the device will function. Its operation somewhat resembles that of a voltmeter, the lower coil being analogous to the permanent magnet of the meter while the upper one furnishes excitation to the movable element on which the contacts are mounted. The relay contacts will close only when the voltage drop across the load, with which the upper coil is in parallel, is enough to cause that coil to excite the movable elements sufficiently to close them. When the load resistance is zero, as in case of a short-circuit, there is no voltage across the upper coil, but when the load resistance is infinite or when open-circuit conditions exist, practically full voltage is impressed across the upper coil, because its resistance is much greater than that of the load-indicating resistor. Consequently it is possible to obtain an intermediate point and calibrate the reclosing relay so that, with a definite value of resistance in the load-indicating resistor, the equipment will not close on a load in excess of a predetermined value.

As long as the trouble on the feeder continues the reclosing relay will remain open, even after the time-delay relay has closed, because the voltage across the load is not enough to close the contacts. As soon as the trouble has cleared, however, and the load resistance has passed the predetermined point, the relay will close, energizing the coil of the feeder contactor which then closes, in turn closing the auxiliary switch (*a*) which seals it in. Closure of the contactor reconnects the load and de-energizes the time-delay relay which opens its contacts.

The equipment for circuits having a combination of stub-end and multiple feed makes use of a contact-making voltmeter to indicate when the potential difference between the feeder and the source of supply has fallen to a safe reclosing value. When the voltage has so decreased, the feeder contactor recloses in the same sequence as in the former instance. A relay connected in parallel with the contact-making voltmeter determines whether the equipment is to operate on multiple or a stub-end feed.

Breaks and Recloses Current as Conditions Require

Men must still be employed to generate power and sometimes, but decreasingly, to superintend its use, but it is needless to have men continuously employed in distributing current and in changing it from alternating to direct.

Problems of Operating Men

Edited by James T. Beard

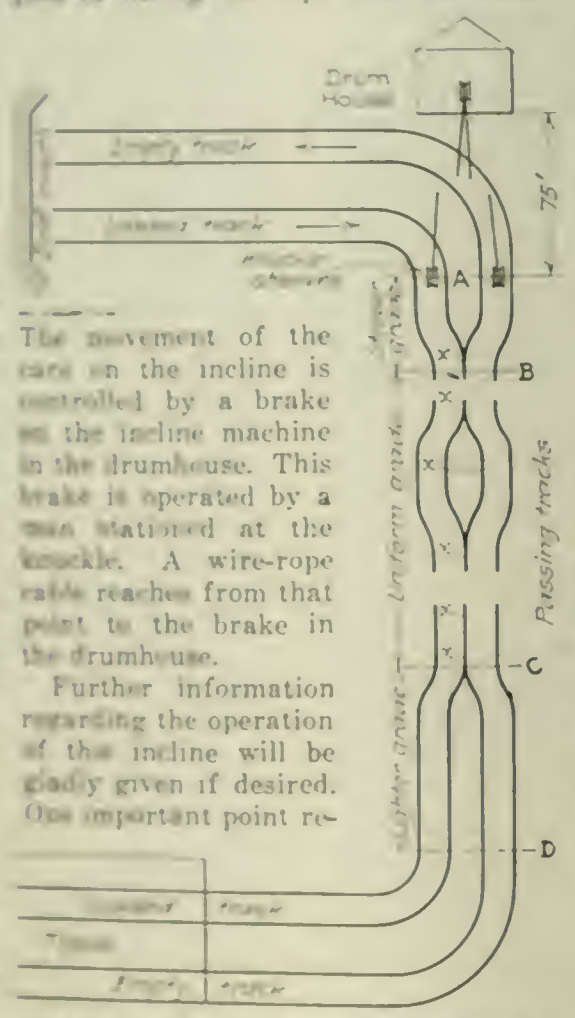
Examples of Successful Gravity Planes

Three-Rail System, Top to Bottom of Plane, with Four-Rail Passing Tracks — Arrangement Wholly Eliminates Switches—Tipple Set on One Side of Incline as a Safeguard Against Runaway Cars

REFERRING to the inquiry of C. M. Shaffner, regarding his proposed installation of a gravity plane, *Coal Age*, Aug. 18, p. 311, kindly permit me to give a brief description of an incline that has been in successful operation for some time, at one of our mines.

In using this, I will refer only to a few of the general features that have a particular bearing on the successful operation of the plane. Without knowing the exact conditions that surround the situation to which reference was made in the inquiry, it is clear that any plan proposed would have to be modified in detail to fit the case in hand.

Three-Rail System Affords Many Practical Advantages



With this premise, let me say I would heartily recommend a three-rail system, extending the full length of the incline, except for the passing tracks midway of the plane, where there must naturally be four rails provided.

The important advantage of a three-rail system is that such an arrangement wholly eliminates the need of switches at any point on the incline. It provides separate loading and empty tracks to be used exclusively by the loaded and empty cars, respectively. This is made possible by the installation of a vertical type of incline machine in the drumhouse, which is located from 50 to 75 ft. above the head of the incline, as indicated in the accompanying figure.

Equipment, Grades and Track Arrangements

There are different types of these machines, adapted to suit different conditions, and a machine should be selected of suitable size and kind to correspond to the weight of cars to be handled and the service intended. This is an important consideration among the forty or fifty different styles and sizes of these machines now on the market.

Referring to the figure, starting at the knuckle, at *A*, for a short distance to *B*, the grade is made steeper than the uniform grade of the incline reaching from *B* to *C*. Then, from *C* to *D* the grade is made much lighter. This is an important feature, as the loaded cars descending the steeper grade *AB* serve to overcome the inertia and accelerate the

The movement of the cars on the incline is controlled by a brake on the incline machine in the drumhouse. This brake is operated by a man stationed at the knuckle. A wire-rope cable reaches from that point to the brake in the drumhouse.

Further information regarding the operation of this incline will be gladly given if desired. One important point remains to be mentioned and that is the setting of the tipple to one side of the incline, in order to safeguard the lives of the men at the foot of the plane, in the event of a runaway car, which is liable to happen at any time. This arrangement also obviates the necessity of providing a safety switch or dropping at the foot of the incline.

RICHARD MACDOUGAL,
Supt., Crafton Branch, No. 8 Mine.
Pittsburg, Pa.

GRADE OF THREE-RAIL SYSTEM FOR A GRAVITY PLANE

ANOTHER LETTER

IN connection with the suggestion offered by D. S. Allison, *Coal Age*, Sept. 14, p. 415, regarding the use of three rails to replace the single track, above the passing point, on a self-acting incline, it may be of interest to state that such a system has been installed by the American Manganese Mfg. Co. of this place, at one of their mines.

At the head of the incline is located a set of tandem wheels, or gravity sheaves, of the type commonly known as "Figure 8." This machine is placed directly under the tracks leading into the mine. As has been stated the three-rail system is only used above the point where the cars pass each other halfway up the incline. Below this point a single track is used.

Plane Equipped with Permanent Cars and Automatic Switch

The automatic switch, at the lower end of the passing tracks, in this case, is operated by a weighted lever that keeps the switch set for the empty track, except as it is forced open by the loaded cars passing down the plane.

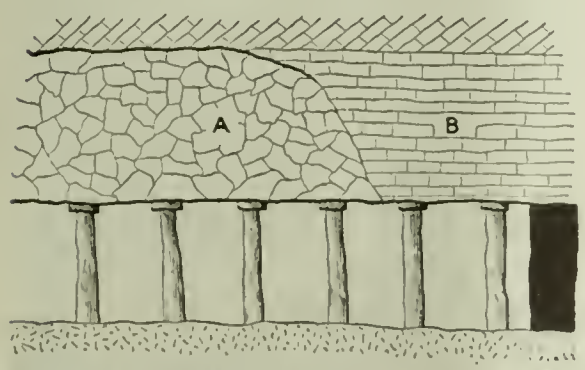
On this incline, there are but two permanent cars used, which are attached to the two ends of the rope, respectively. These cars are equipped with drop doors, at their lower ends. As a car reaches the foot of the incline the door is automatically raised by an attachment and the car dumps its load, after which the door again closes, locking with a spring catch.

At the upper end of the incline each car passes under a bin, located at the entrance of the mine, where it is loaded and is then ready for another trip. While only a small car is used at the present time, this arrangement is capable of handling an output of 500 tons in 8-hr. Its operation has given complete satisfaction.

Dunbar, Pa. JOHN STANNIS.

Room Timbering

Cantilever action of roof follows extraction of coal — Permanent posts should not be carried too close to the face — Temporary posting there will often avoid breaking of timbers— Systematic timbering advised.



REFERRING to the question asked by "Timberman," *Coal Age*, July 27, p. 136, asking the best method of timbering rooms in a 6-ft. seam under 250 or 300 ft. of cover, with a good roof and bottom, I would like to make the following suggestions:

It is important, of course, to use timbers of a suitable size. In this 6-ft. seam the small diameter of the posts should not be less than 6 in. Good cap pieces from 3 to 4 in. should be used over the posts, but it will not be necessary to use foot boards.

Assuming that these conditions have been complied with and that the rooms are driven systematically, the continued breaking of the posts under this cover would seem to indicate that there is a greater pressure operating than that due to the weight of the overburden alone.

Cantilever Action of Roof Follows Extraction of Coal

The extraction of the coal always develops a cantilever action in the roof. In my sketch I have tried to illustrate the effect of this action. The gradual settlement of the roof on the timbers causes the strata to break a short distance back from the face of the coal. In the figure the portion A represents

STRATA BREAKS A SHORT DISTANCE FROM FACE OF COAL

the area of complete settlement, while that marked B indicates where settlement is in progress.

As explained in the reply to this inquiry, the unbroken strata above overarches the opening, causing the weight of the overburden to rest on the ribs, and the weight of the loosened portion A above rests on the permanent timbers beneath it.

Posts at the Coal Face Must Not Be Set Too Tight

The point I wish to emphasize is that temporary posts should be set under the solid portion B close to the face. If these posts are set tight between the hard roof and floor they will be broken by the weight coming on them, being subjected to a much greater pressure than the permanent posts farther back from the face.

If the breaking of the posts is more pronounced and continuous within a limited distance of the face it would seem that the posts have been set too tight under that portion of the roof. On the other hand, if the breaking of the posts extends further back from the face we must look elsewhere for the cause.

It is a good plan to drive several rooms abreast of each other and at a uniform width and distance center to center and watch the effect in producing a more uniform distribution of pressure. It might be well to use a line of light cogs up the center of the room instead of the middle line of posts. This would be expensive, however, and can only be advised as a last resort.

Caps Being Crushed Show Posts Are Set Too Solid

From the statement that the caps do not appear to serve their purpose when the posts take the weight, I infer that the trouble occurs at the face rather than down the length of the room. I naturally conclude that the compression of the caps is not sufficient to allow for the settlement that must take place.

That being the case, it is not strange that the posts are broken since, as stated in the reply to the inquiry, the weight of the overburden is far in excess of the strength of the timber. Since this settlement is irresistible, the most practical course to pursue is to make the posting at the face temporary and not drive them tight.

The conditions described would also suggest the advisability of adopting a systematic method of posting by which the roof pressure will be more equally distributed.

I. C. Parfitt.

Washington, D. C.

Testing of Safety Lamps

Every lamp must be tested—Opinions differ in regard to character of test—Use of lamps approved by the Federal Bureau—Blowing test effective if properly made.

IN HIS letter regarding the testing of safety lamps, *Coal Age*, July 13, p. 60, Joseph Cain raises the question as to whether the method of testing a lamp by blowing against it, as he has described, should not be adopted at all mines where such lamps are in use. Mr. Cain also asks whether it is possible to tighten a lamp to such an extent as to endanger the breakage of the glass through expansion due to the heating of the lamp.

It requires no argument to prove that a safety lamp should be tested for any defects, either of construction or assembly, before being entrusted to a miner. However, the manner in which this testing should be done is a question on which all may not agree. Before the lamp is assembled, it must be carefully examined in every part to ascertain if they are in perfect condition and there are no defects that would render the lamp dangerous.

Purpose of Federal Bureau of Mines Testing of Safety Lamps

When a lamp has been assembled its further testing is for a twofold purpose: 1. To demonstrate that it will not pass the flame in a current of high velocity. 2. That it will not pass the flame by reason of an internal explosion, under any conditions that may reasonably be expected to arise in the daily operation of the mine.

As far as I have been able to observe, very few mines have facilities for making a test to demonstrate the first of the two conditions mentioned. In fact, such a demonstration is not necessary, inasmuch as all approved lamps have been subjected to such tests at the Federal Testing Station. The fact that they have been approved by the Bureau of Mines is evidence that they have stood those tests successfully.

My point is that no mine should be worked with any other than approved safety lamps, if safeties are required at all. Then, if these lamps are maintained properly, there will be no necessity of their being subjected to a further test to ascertain if they will pass flame in a current of high velocity.

Testing for Internal Explosion More Important

Personally, I consider the testing of a lamp, for the second purpose named, of far more importance in determining its safe condition. As a matter of fact, there are few mines in which the velocity of the air current is as great as that to which the lamp has been subjected in the Federal Bureau test. Such velocities, if they occur at all, would only be found on the main intake and return airways of a mine.

Now, regarding the blowing test mentioned by Mr. Cain, it might be said that custom has sanctioned this practice, which has been in use a long time, in most localities, chiefly owing to its thoroughness and reliability, which is apparent to everyone. My experience is that when a lamp has been properly examined and assembled there is little danger of its being unsafe, except that it may leak air around the asbestos washers and these gaskets should receive careful inspection.

Hardening of Gaskets

At times, the gaskets become hard from long use and continued compression, which gives them a glazed surface and makes them ineffective, particularly if they are dirty. To remedy such a condition, the washer should be scraped to remove the compressed dirt and produce a soft surface that will form a better contact with the glass; or new gaskets must be used in place of the old ones.

In regard to the flame of a safety lamp being extinguished by the carbon dioxide contained in the breath, as suggested by one writer, it should be remembered that the purpose of the blowing test is to ascertain if the flame is at all deflected by reason of the air blown against the lamp entering the combustion chamber. If the flame is at all disturbed or deflected, the lamp is unsafe. It seems to me that the extinctive effect of the breath is immaterial, in respect to ascertaining the security of the lamp.

Making the Blowing Test

In making this test, I have found that the lips should be placed in close contact with the lamp, at the suspected points. If the lamp is held even a short distance away from the lips, the air blown against it is deflected by the circular form of the lamp, and the effectiveness of the test is destroyed. This may not seem sanitary, but it makes

the last a safe one. For the purpose mentioned, I consider that the blowing test, if properly made, is one to be strongly advocated.

THROUGH THE LAMP

While I do not regard the tightening of the lamp, before it has become heated, as being particularly dangerous, I would not advocate the practice if there is any possibility of the lamp being strained for any length of time in a dust atmosphere charged with gas, such as a feeder will frequently encounter. Lamps burning a volatile oil are very susceptible to temperature changes. Such lamps should be light and only sufficiently to secure an air tight joint around the top and bottom of the glass cylinder, and this should not endanger the glass by reason of expansion through heating.

Washington, D. C. I. C. PAGETT.

ANOTHER LETTER

IN DISCUSSING the question of properly testing a safety lamp before entering the mine, some writers have claimed that when it is possible to blow out the light of a safety lamp, either the lamp has not been put together rightly or there is some defect in its construction.

It has always been my understanding that something is not right when a light can be extinguished by blowing into the lamp; but, today, many safety lamps can be put out in this manner. If anyone doubts that statement, let him blow through the orifices of his lamp, just below the glass.

CIRCULATION ABNORMAL

While it may not have a direct bearing on the subject matter of this discussion, I think it will be well to draw attention to two features that have not as yet been mentioned regarding the construction of safety lamps. The first has reference to the air entering the lamp at a point below the flame, so that the circulation within the combustion chamber and the chimney of the lamp will be economical.

It is well known that where the air enters a safety lamp through the lower part of the gauze chimney and above the glass, it must descend in order to reach the flame. This is the trouble with the old type of Clanny lamps. The descending and ascending currents thus formed within the combustion chamber always cause the lamp to smoke. Moreover, there is formed what I would call a wall of burnt air or "afterdamp" (CO_2) that settles around the flame. This wall of extinctive gases not only dims the lamp, but makes it impossible to test correctly for firedamp.

EFFECT IF CARBON DEPOSITS

It may be argued, and it is true to a considerable extent, that the presence of carbon dioxide in the combustion chamber will lessen the force of any explosion that might occur within the lamp, which is very liable to happen when the lamp is in the hands of a careless fireboss.

Owing to the relighting devices, in many safety lamps in use today, a fireboss is apt to be less careful in making tests for gas. He will often run the risk of an explosion within his lamp. However, most of the lamps equipped with relighting devices enter the air below the flame, thus creating an upward circulation within the lamp and clearing the combustion chamber of excessive gas. This construction, I believe, reduces the liability to danger from internal explosion.

PREFERENCE FOR SMALL LAMP

The second feature to which I want to refer relates to the size of the gauze chimney. To my notion, a small lamp is stronger and better able to stand hard usage. It occupies less space, is easier to handle and a thin layer of gas at the roof is more readily reached when the height of the lamp is reduced.

Present day practice, with a large number of our firebosses, is to carry an electric lamp in their cap, which gives a good light and helps to expedite their work. It is this custom that has given rise to a desire for small testing lamps.

Linton, Ind. W. H. LUXTON.

[The reference of this correspondent to the desire of some fireboss to use a small lamp recalls the attempt made some years ago to introduce a miniature Davy lamp, for the purpose of testing for gas in mines. When the knowledge of this came to the late James E. Roderick, then chief of the Department of Mines, in Pennsylvania, it brought from him a prompt protest against the use of such lamps, as being dangerous for many reasons.

STANDARD SIZE OF LAMP DETERMINED

First, the size of the lamp and the small space inclosed within the gauze chimney, it was claimed, made the little lamp a menace to safety when exposed to a body of gas in the mine. Again, its small size made it an object that would naturally be tucked away in the pocket of a fireboss or foreman, where it would accumulate dirt, be upset and leakage of oil would render it unsafe for testing.

As the result of protracted experiments, the eminent chemist Sir George Humphry Davy, found that the best results were obtained in the use of what has since become a standard gauze for safety lamps, containing 28 wires (No. 28 B.w.g.) to the inch, or 784 openings per square inch. Davy drew attention to the danger arising from the use of gauze chimneys of too large a size, as in the old Scotch Davy; or a chimney that was too high, as in the Pieler safety lamp. Similar danger also exists in the use of too small a gauze chimney, by restricting the volume within the lamp.—EDITOR.]

Inquiries Of General Interest

Use of Single and Double Cables for Electric Gathering Locomotives

Large Percentage of Single-Conductor Gathering Reels in Use — Track Requirements — Two Types of Double-Conductor Cables—Advantages of Single- Over Double-Conductor Cables

AFTER reading numerous valuable replies to inquiries that have appeared in *Coal Age*, I have decided to ask for a little information myself. We are developing a new mine in which we plan to operate gathering locomotives. Up to this time, however, we have been unable to decide whether it is better to use a single or a double cable to permit the locomotives to reach the faces of the rooms in the mine. My personal preference is for the single type of cable, for many good reasons that I will not take the time now to state. But our foreman says he has never used the single type of cable and is inclined, therefore, to favor using the double cable. One of these double cables has been and is still in use in our mine, and the foreman argues that it is well to let good enough alone and not experiment with a type of cable that we have not used before.

As I regard the situation, inasmuch as we expect to use several of these cables in the future, it is important to ascertain the views of *Coal Age* and others regarding the relative advantages of these two types of conductors, in gathering-locomotive haulage. My purpose in asking this information is to ascertain the most economical method of operating gathering locomotives equipped with reel and cable so they can reach the face.

Stillwater, Ohio. ELECTRICIAN.

In order to obtain first-hand information on this subject, we have asked Graham Bright, general engineer for the Westinghouse Electric & Mfg. Co., to give the readers of *Coal Age* the benefit of his knowledge and experience, regarding different types of gathering conductors. Mr. Bright writes, in substance, as follows:

"A large percentage of electric gathering reels are of the single-conductor type. In mines where the rails, on room entries and in the rooms turned off those entries, are laid with a fair amount of care and the fishplates bolted up so as to afford a good rail return for the electric current, there is no true reason why a single-conductor cable will not give satisfactory service.

The double-conductor cable has been used largely, in the past, where wooden rails were laid in the rooms; or where iron rails were used but improperly laid and the fishplates loose or missing. Under these conditions, it is quite evident that a single cable could not be used to advantage, if at all. Today, most of the mines realize the importance of keeping their tracks in fair condition, as derailments are not only expensive but affect the output to a very considerable extent.

There are two types of conductor cables; namely, the twin-conductor cable, consisting of two parallel wires bound together to form a single cable, and the concentric type of cable. I regard the latter as being much superior to the former. Most of the double-conductor cables manufactured have been of the twin-conductor type, which is very difficult to reel up evenly, and makes the operation even harder of accomplishment when it becomes necessary to use a cable that has been spliced.

During the last few years, I have been recommending the concentric type of double-conductor cables, wherever it is necessary to use a double cable owing to poor track conditions. The concentric type has the advantage that it reels much more evenly than the twin-conductor cable. In the concentric type, the ground side being outermost, no particular damage is done if the outside layer of insulation becomes worn off in operation. Though, in the use of this type of cable, repairs may be a little more difficult, this disadvantage is more than counterbalanced by the advantages gained.

Allow me to advise that wherever possible the single-conductor cable should be used, with a type of reel having a small inertia in the drum, which will insure easy winding and prevent the heavy stresses caused by a type of drum having a large inertia. It is my belief that money spent in providing a fair rail return, on side entries and in the rooms, will more than balance the extra cost of double-conductor cables and the consequent high cost of maintenance and additional delays.

Examination Questions Answered

Indiana Mine Bosses' Examination Indianapolis, 1922

(Selected Questions)

QUESTION—*Discuss the subject of mine ventilation, setting forth the purposes; mechanical devices and their uses; quality of air required and how determined; quantity of gas and how determined; humidity and temperature, how determined; mine gases, how detected; their danger and how prevented; and give the law respecting mine ventilation.*

ANSWER—Briefly stated, the purpose of ventilation is to furnish pure air throughout the mine, by conducting an air current in one or more splits so that it will sweep the working faces, in quantity and velocity to dilute and carry away the noxious gases that accumulate in the workings.

Many small, non-gaseous mines are ventilated by a furnace constructed near the foot of the air shaft. In all the larger and up-to-date mines, however, either a centrifugal or a disk fan is used to force the air into the mine or exhaust it from the mine. In either case, a free circulation of air is produced in the airways and throughout the workings.

The Indiana Mine Law requires the circulation of 100 cu.ft. of air per minute, for each person, and 300 cu.ft. per minute, for each mule, employed in the mine. The air is measured by means of an anemometer, which shows the velocity of the current, and that multiplied by the sectional area of the airway gives the volume of air in circulation.

The percentage of gas in the return air current is first estimated by observing the height of the flame cap in a safety lamp exposed to the current. Taking this percentage of the total volume of air in circulation gives the quantity of gas generated in the mine.

The humidity and temperature of the mine air are ascertained by observing the readings of the wet-and-dry-bulb thermometer. This instrument is often called a hydrometer or psychrometer. The reading of the dry-bulb thermometer determines the temperature of the air.

Mine gases are detected mostly by observing the effect of the gas on the flame of a safety lamp. Methane or marsh gas causes a flame cap, while carbon dioxide makes the lamp burn low or puts it out entirely. Carbon monoxide is generally detected by observing its effect on small birds or mice confined in a cage. Hydrogen sulphide is detected by its smell.

Carbon dioxide is dangerous when accumulated in low and badly ventilated places in mines, because the gas contains no available oxygen for the support of life, and its presence depletes the oxygen of the air, causing suffocation and death. The other three gases named are inflammable and form explosive mixtures with air.

These dangers are prevented, as far as possible, by providing an ample ventilating current to sweep them from their lurking places in the mine.

The Indiana Mine Law (Chap. 258, Sec. 11) requires that 100 cu.ft. of air, for each person, and 300 cu.ft., for each mule, be kept in circulation, in all main and cross-entries and working places in the mine, to an extent to keep it free from standing gas and in a fit state for work. The law further provides for the examination of the mine by a competent fireboss using a safety lamp, the examination to be made before each shift.

QUESTION—*Discuss haulage tracks in mines with respect to bed, gage, weight of rails, ties and nails, fishplates, curves, grades, switches, ballast, drainage; and give the law respecting wide entry and refuge holes.*

ANSWER—All tracks on haulage roads must be well bedded and drained by a suitable ditch at the side of the road. Main roads should be well ballasted with good material. The gage of the track, weight of rails, ties, nails and fishplates must be determined by the size and capacity of the mine cars used. This is largely modified by the height of the seam as determining the headroom on the roads. In general, in locomotive haulage, a 3 or 4½ ft. track gage is used, with rails varying from 40 to 60 lb. per yard, fastened by 4½-in. spikes to 6- or 8-in. ties and bolted together with fishplates to fit the rails.

The grades on the main roads, as far as possible, should favor the movement of the loaded cars, a 1 per cent grade being preferred where this is practicable. Sharp curves in the track should be avoided and all switches must be carefully laid by competent trackmen.

The Indiana Mine Law (Chap. 197, Sec. 1) provides for a clearance space, on one or both sides of a road continuously, of not less than 2 ft., measured from the rail to the rib. This space must be kept free of all obstructions such as props, loose slate and other material. This does not apply to mines in the block-coal fields, working Seams 3 and 4, commonly known as the lower and upper veins, in Indiana. Chap. 258, Sec. 12 provides for refuge holes, not less than 3 ft. deep, measured from the side of the car, and 4 ft. wide, at distances not more than 20 yd. apart, to be constructed on all single-track haulage roads using power, and on all gravity inclines on which persons employed in the mine must travel often, in going to and from their work.

State of Indiana Mined Coal at $8.70 Per Ton During the Strike

Financial results from James A. Cooper, federal receiver for the Sterling Fuel Collieries Co., of Staunton, Ind., show that the cost of digging during the coal strike was $8.70 a ton, for which the state paid the company $4 a ton, a loss of $4.70 a ton accruing to the company for which it is making no reparation or indemnity. Attorney General Smith of Indiana said the cost of maintaining the 1,500 militiamen in the field was approximately $50,000. Approximately 1,064 tons of coal was mined under state protection, making the cost per ton about $47.00.

In a letter from Mr. Cooper it is set forth that the stockholders, bondholders and creditors of the company joined in heavy support of the law. He pointed out that a great deal of the apparent loss would have accrued to the company at any time it resumed its mines as the damage of the mines had wrought havoc to the equipment. The expenditure of maintaining the soldiers, Governor McCray points out, was made in the same spirit in which a city council appropriates a certain sum annually for the maintenance of the police department for the protection of its citizens.

Utah Coal Mining Feels Awakening In Western Steel Industry

Utah coal probably soon will be used in greater volume as one of the bases for the expansion into Utah of big new steel enterprises on the Pacific coast. Already the Columbia Steel Co., a $15,000,000 corporation formed in July, is getting ready to build the Carbon County R.R. to its coal fields near Sunnyside which are owned by the Utah Coal & Coke Co. L. F. Kaiser, president of the Carbon Coal Co., will be at the head of the railroad company. The other big move into Utah is being made by the newly organized Pacific Steel Corporation, which is a consolidation of coal properties up and down the coast owned by the Pacific Coast Steel Co. and the Southern California Iron & Steel Co., and of iron ore and coal properties in Utah owned by the Milner estate.

The ore bodies in Iron County held by this new merger total about 4,000 acres and the coal properties, largely in Carbon County, about 8,000 acres. About 25 miles of railroad will be constructed by interests allied with the new Pacific Steel Corporation.

Distillation of Coal from Oil Makes Rapid Strides in Great Britain

There has been a remarkable increase in the use of oil fuel in England during the last fifteen years. During this time the complete substitution of coal by oil fuel in the navy has been effected. In the mercantile navy the development has been slower, but during the year 1920-1921 58 per cent of the new vessels classed under Lloyds register were fitted for burning oil fuel.

The natural source of fuel in England is, of course, coal, followed at a considerable distance by peat and oil shale. Regarding the latter it is improbable that under present conditions the output of Scottish shale oils can be increased by an amount which will have any appreciable bearing on the problem. Since the great part of the heat units present in coal as mined appears in metallurgical coke it forms an excellent and absolutely smokeless fuel, and it is necessary for the commercial success of that process that domestic users appreciate its superiority.

The results of an investigation of the oil produced at East Greenwich by the distillation of coal in shallow trays in horizontal retorts show that from 12 to 18 gallons of oil can be obtained from a ton of dry coal. In this connection the experiments of Dr. Bergius on the hydrogenation of heavy oils and tars, and on bituminous coal, has opened up considerable new possibilities in the production of liquid fuels from coal. In this way the yields of petrol, diesel oil and fuel oil from coal can be enormously increased. In fact Dr. Bergius has actually succeeded in liquefying coal and in introducing oil into the coal to combine with the coal and produce the oil.

Peace Prevailed to the End at Cleveland; Reorganization Committee Starts Work Nov. 14 at Chicago

What the Conference Did

Enabled operators to compose many violent differences and to discover much "common ground," leaving them more nearly unified than at any time in years.

Created a "reorganization committee" of two miners (one a district president) and two operators from each of the 15 districts whose operators attended the conference, with a vague understanding that other districts can come in.

Instructed this "two-by-two" committee to suggest a method for negotiating future wage contracts. It is understood that the committee is not to report until the new United States Coal Commission does and that nobody is bound to accept its recommendations, though all parties hope to.

Instructed this committee to organize in Chicago Nov. 14 and reconvene the joint conference again to hear its report on or before Jan. 3.

Did not set up a joint fact-finding board, thus studiously leaving the field clear for the United States Coal Commission, representing the people.

Operators declined to comply with Washington's request for twenty names suggested by the conference for the new federal commission. Miners suggested 10.

Miners' scale committee, after the conference, reaffirmed the platform of wage and conditions demands formulated at the miners' convention Feb. 14-17, 1922.

"Peace to the end" was adhered to with determination in the wind-up of the joint miner-operator conference in Cleveland, Ohio, last week, as forecast in these columns. The bitterness among operators on Monday, Oct. 2, the opening day of the meeting, was smothered into the background on Tuesday, a day of give and take, and on Wednesday the partly settled program of conference decisions was put through calmly and with doors open to the public. The fighting was all over.

So the conference proceeded to set up its joint committee to work out and suggest a method for future negotiations; it agreed not to comply with the Washington request for twenty names for President Harding to consider in appointing the United States Coal Commission, and it simply "omitted" to set up any joint fact-finding commission of its own because it was the desire of the conference to do no act that would appear in the light of interference with the people's investigation of the coal industry. Since the miners wished to supply President Harding with a panel of names, they were permitted to do so after the conference adjourned. But the operators, many of whom have already submitted lists in response to requests from the administration, declined.

When the conference adjourned, about the middle of the afternoon on Wednesday, both sides agreed that no such display of harmony between miners and operators, and among operators' groups had been seen in many a year. They all declared that a new era of good feeling might easily be starting from this conference. There was some difference in tone in some of the after-conference statements, however.

Watkins Commends Lewis' Conciliation Speech

T. H. Watkins, president of the Pennsylvania Coal & Coke Corporation, declared that the spirit displayed by both sides had been splendid and that he had never seen such harmony prevail in a joint meeting. He said the conciliation speech of John L. Lewis, president of the miners, on Tuesday morning, was a fine declaration and went a long way toward harmonizing the whole conference. Mr. Watkins felt very optimistic for the future of relations between miners and operators.

T. K. Maher, of Ohio, who with Mr. Watkins and W. H. Haskins, of Ohio, was largely responsible for the settlement of Aug. 16 with the miners, agreed that a fine spirit pervaded the meeting and that the conference was entirely satisfactory.

"There was carried out here," said he, "not only the letter but the spirit of the Cleveland agreement. The first factor that contributed to produce harmony was the speech to the operators by Mr. Haskins, in which he made it plain that the little group which first signed the Cleveland agreement intended to stand by it here, even if they had to do so alone. The second factor was Mr. Lewis' speech and the third was Mr. Watkins' able analysis of the problems that confront us and what this conference ought to do."

In the test of strength between the "small group" of operators who broke the strike in August and the majority there was much belligerence. Mr. Maher, of the "little group," finally was conceded the temporary chairmanship of the joint conference, but Phil Penna, of Indiana, was made chairman of the operators' separate sessions, with W. D. McKinney as secretary, and also was chosen permanent chairman of the conference.

There was difference of opinion as to whether the letter and spirit of the Cleveland agreement had been carried out. Many operators and groups who went to the conference uncommitted to take part, finally did so when it became apparent that no minority was to dictate policies as it did in the making of the Cleveland agreement and that therefore the spirit of this conference differed widely from that of the Cleveland meeting in August. They felt that the harmony of this conference was no result of bludgeoning by anybody but resulted from a realization by operators and miners alike that the only hope of doing business in the future lay in unity groups. Therefore the operators effected what chairman Penna called "a cohesion."

Common Sense, Not Threats, Did It

"Common sense, not threats, and Lewis' speech were responsible for our final harmony," said H. N. Taylor, president of the Central Coal & Coke Co., of Kansas City, a man who was an outstanding figure throughout the conference, "and the outcome of it all was most satisfactory." When he was asked how permanent he felt the new harmony was, he replied: "I think it is as permanent as the harmony effected in 1898. Operators went into that meeting with such hatreds that they didn't know each other. They made peace. It lasted for twenty years or even longer."

Said Phil Penna: "The operators never can be as united as the miners for they are competitors among themselves and have far more conflicting interests than any union groups have. However a real unity was accomplished among them here."

"Both sides saw the necessity for harmonious action," commented John L. Lewis, miners' president, "and I am heartily glad that it was taken. The manner in which the business of the conference was dispatched augurs well for the future of the coal industry."

Peace at the conference was so infectious that it pervaded even the relationships between President Lewis and Frank Farrington, recalcitrant president of the Illinois miners, whose bitterness against Lewis has been obvious for a long time. Farrington received committee appointments at the hands of Lewis and the two appeared to make it a point to meet several times and converse pleasantly in public.

The joint conference was called by President Lewis and by T. K. Maher, chairman of the August Cleveland meeting, thus following out the terms of that meeting. Under the agreement which ended the strike, the two main purposes of the joint conference were to choose a joint committee to set up machinery for future wage agreements and to name a joint fact-finding commission within the industry. If the conference failed by Oct. 10 to agree upon this fact-finding commission, then President Harding was to be asked to

operators on the committee are: District 6, Ohio, Michael Gallagher and James H. Pritchard; Iowa, E. C. Smith and George Heaps, Jr.; Kansas, W. L. A. Johnson and Ira Clemens; West Virginia, Joseph Purseglove and C. H. Jenkins; Arkansas, Oklahoma and Texas, M. McWilliams and one to be chosen; Wyoming, H. C. Marchant and one to be chosen; western Kentucky, C. W. Taylor and F. D. Rash; Michigan, R. M. Randall and Warren Pippen; Missouri, F. W. Lukens and H. N. Taylor; Indiana, Hugh Shirkie and M. L. Gould; Washington, J. H. Wallace and one to be chosen. Illinois, central Pennsylvania, Pittsburgh and Montana are yet to name their members.

On motion of President Lewis this "two-by-two" committee will have its first meeting at the Great Northern Hotel in Chicago at 11 a.m., Nov. 14.

Thus the main scheduled business of the joint conference was finished and the conference adjourned to be reconvened at the call of the "two-by-two" committee whenever that board is ready to report. It was the general understanding throughout the conference that that committee is to wait until the new United States Coal Commission produces some results before it completes its plan, for the whole feeling of the conference was that the federal investigation is to be given a clear field and that its recommendations are to be adopted as far as possible.

As Phil Penna put it: "Everybody in the coal industry has tried to put our own house in order in the past and failed. Now the people should be given a chance to do it for us."

It was also understood that whatever recommendations the "two-by-two" committee may make are not necessarily binding upon either miners or operators though everybody concerned gives evidence of hoping that the recommendations will stand. President Lewis of the miners said as a final word from his side that he "hoped" the committee would be successful in working out an acceptable plan.

Miners Stick to 1922 Demands; Lewis Almost Sure to Be Re-elected

Immediately after the "peace conference" of miners and operators in Cleveland, which ended Wednesday afternoon, Oct. 4, the policy committee of the miners' union assembled, conversed briefly and announced that the platform of demands for wages and conditions which was adopted at the Indianapolis convention in February, 1922, had been reaffirmed. Thus whenever the time comes for the presentation of demands for the next wage agreement the miners will demand a continuance of their present wages, as well as a six-hour day, five-day week, time and a half for overtime, double time for Sundays and a correcting of machine differentials and certain other elements of the existing working agreement. While this program was adopted early this year the miners have never presented it. The reaffirming of this set of demands eliminates the necessity of another miners' convention to formulate new demands.

It became known at the end of the Cleveland conference that President Lewis' re-election as chief officer of the International United Mine Workers was assured. Nominations for the next election, which are now in, made Lewis the choice of between 1,600 and 1,700 union locals, while George Mercer, statistician in District 12, generally referred to as a "Farrington candidate" of the rebellious element in the union, won the nominating votes of only about 128 locals. The names of Lewis and Mercer are the only ones to go on the ballot for the election. While a number of locals attempted to nominate Alexander Howat, of Kansas, to run against Philip Murray, of Pittsburgh, for vice-president, it was officially stated that Howat's name would not be permitted on the ballot because he is not recognized as a member of the union, never having been reinstated after his ejection with his entire group of Kansas officers nearly two years ago. William Green is guaranteed the nomination and election to continue as secretary-treasurer.

F. R. WADLEIGH, who now is devoting most of his time to matters connected with the office of the Federal Fuel Distributor, has been looking into the anthracite situation during a visit to Pennsylvania fields.

Fact-Finding Commission Should Seek Improvement of Coal Industry, Not Act as Tribunal

By Paul Wooton
Washington Correspondent of *Coal Age*

Washington, D. C., Oct. 9.—Developments of the last week have caused officials concerned with coal to take a much less encouraging view of the situation than at any time since the strike was settled. There is a general belief that the peak of production has been reached and that a decline in output may be expected. The public believes the shopmen's strike is over. As a matter of fact it is continuing on a number of roads and some of those roads are vital in effecting the maximum coal production. Even on those railroads where the strike is settled, unusual difficulty is being experienced apparently in effecting an equitable distribution of available cars. Car supply is spotty and uncertain. The non-union districts are suffering particularly. Their cars were sent broadcast over the country during the strike and great delays in their return are occurring. Incidentally as a result of that situation, Western mines have a proportionately better car supply. The fact that the surplus of empties has been exhausted and the increasing pressure of other freight along with the difficulties in obtaining compliance with service orders and car rules and regulations make for increasing difficulties in supplying mines with coal cars.

It is clear that the more critical part of the situation is to obtain the distribution of household fuel. Every effort is being made at the office of the Federal Fuel Distributor to meet that situation. It is known that there has been no extensive substitution of anthracite. It is recognized that that situation is one in which the operator can do little. It is entirely a problem of inducing the retailer to exert his influence with the consumer to induce him to lay in a supply of bituminous coal or coke.

While the coal strikes still in progress have only a small influence on coal production, they are having serious consequences in creating a shortage of gas coal and in their influence on beehive coke production. The strike in the Greensburg-Westmoreland district is chiefly responsible for the bad situation with regard to gas coal, while the strike in the Connellsville district is so limiting the output of beehive coke that there is no surplus, which was being counted on to substitute for anthracite.

There is general disappointment that production at its apparent peak fell short of the 10,000,000-ton mark. If no better showing was made in September under certain advantages that will not exist in October or again this year there is little hope of producing enough coal to meet the full requirements of the winter. The entire September production was necessary to meet current requirements. It is believed that very little of it went into storage. If surpluses are not made available in October the dangers of the situation are increased, particularly if severe weather conditions should occur during the late autumn and early winter.

Officials generally are pleased by the developments at Cleveland. To have had another commission studying the coal situation would have been embarrassing in many ways and would have been a distinct burden on the industry. At the same time the decision to study the wage-agreement problem meets general approval, as it is regarded as certain that the government's fact-finding commission will favor bargaining within the industry rather than the setting up of a coal labor board.

As is evidenced by several provisions in the act creating the fact-finding commission, the framers of the law—for the most part lawyers—could not get away from the idea of a court. Those officials closest in touch with the coal situation hope that the commission is not going to devote too much of its time to the calling of witnesses and the taking of testimony under oath. They prefer seeing the problem approached in a student-like manner with emphasis on the desire to give sympathetic attention to any proposal which has as its object benefit of the coal industry.

The hope also is expressed that the commission will not divide itself into two parts, one to consider anthracite and the other the bituminous situation. It is believed that the two industries should be studied together since the problems of one have their counterpart in the other. Anthracite, for instance, would be a most instructive exhibit in considering the overdevelopment of bituminous mines. There would be much gained by viewing the industries side by side, so that full advantage could be taken of their contrasts. It is also hoped that the commission will possess a sufficient aggregate of courage to recommend whatever drastic policy may seem best to meet the situation. It is being called upon to provide a constructive program for two generations to come. The thought is that few problems on the horizon are as important as that of coal. Heat is essential to life. Power is essential to industrial civilization. Each must be had in quantities sufficient to meet all requirements and must be cheap if the nation's prowess is to be maintained. There is much more before the commission than an effort to work out a plan whereby capital and labor may live in the same house without demolishing it as an incident to internecine strife.

Spens Simplifies Order on Daily Reports

Under date of Oct. 4, 1922, Fuel Distributor Spens modified his order No. 1 calling for daily reports of coal shipments. The modifications permit the omission of names and addresses of consignees and car numbers and initials by all who will keep such a record in their offices. Instead shippers are required to note the number of carloads of coal shipped to designated classes of consignees, as "steam railroad," "public utility," etc. Shipments to tidewater and the Lakes may be so designated.

Shipments to other than consumer, as to tide, to wholesaler, or to scales, must be reported as such and the producer is to be held responsible for the ultimate reports from the middleman as to the destination of the cars.

The order follows:

ORDER OF FEDERAL FUEL DISTRIBUTOR OCT. 4, 1922

Paragraph 11

(a) To facilitate reporting and assure the earliest possible receipt by the Federal Fuel Distributor of the most essential information immediately required, compliance with that provision of clause (b) of Regulation II requiring the daily report of names and addresses of all consignees, with car numbers and initials is hereby waived as to all producers who shall thereafter keep and preserve full and detailed records showing such data in such form as to enable them promptly to furnish such information as to any shipment if and when required in any particular case.

All such producers, when reporting upon the form prescribed by Regulation III may at their option—

Omit any entry in the columns headed respectively "Consignee" and "Office Address" and in the column "Car Nos. and Initials" state merely the number of carloads in each shipment.

The "Nature of Consignee's Business" should be designated, where applicable, as "Steam Railroad," "Public Utility," "Wholesaler," "Dealer, for Domestic Use," Industrial (such as "Iron and Steel," "Textile," etc.), and like designations.

In giving the "Destination of Shipment" state place of destination or "Tidewater" or "Lake," as the case may be.

(b) In all cases where the coal is shipped from the mine to scale, to tidewater or lake ports for transshipment, or to selling agents or other representatives of the producer for sale and reconsignment, the producer shall make daily report of all such shipments upon the form required by Regulation III, giving as to such coal all of the information required by such form so as to

Distribution of Lake Cargo Coal Loaded at Lake Erie Ports to Oct. 1*

Morrow and Callahan Resign as Officials of National Coal Association; to Form Selling Company

J. D. A. Morrow, vice-president of the National Coal Association, and John Callahan, its traffic manager, have resigned from these offices and will establish the Morrow-Callahan Coal Co., which will act as a selling agent for a few well-known coal producers who will be associated with the firm.

While it is believed that these officials of the National Association would have taken this step sooner or later, regardless of the situation within the National Coal Association, there is reason to think that they were influenced to embark in business for themselves at this time by the lack of support being given that organization.

At the present time the National Coal Association represents less than 50 per cent of the country's bituminous production. Mr. Morrow frequently has urged upon bituminous operators the necessity of having within the organization the maximum possible amount of the country's production. It always has been recognized as impossible to have 100 per cent of the production represented in any organization of operators. This is due to the fact that many mines are owned and worked by manufacturing concerns or other consumers as a mere incident of their business. Such operators of coal mines as public utilities or steel makers, for instance, are not immediately concerned with the welfare of other producers of coal. In many instances they are particularly anxious not to align themselves with the operators whose principal business is the production of coal. Nevertheless there is at least 75 per cent of the country's production which reasonably might be expected to join in a national association.

One of the outstanding results of the study of trade associations which has been made since the Supreme Court's ruling in the Hardwood case is that industry must have a practical point of contact with the federal government. Coal is too essential to the public welfare for the government to have to turn to several thousand individuals in an effort to secure information. It is admitted almost unanimously that there must be someone in Washington authorized to represent the bituminous industry. Such a representative must be supported by a staff.

Unwilling to Occupy False Position

Mr. Morrow is believed to have felt that the association is such an obvious necessity that it should have the unanimous support of no less than 75 per cent of the country's bituminous production. When it became apparent that this measure of support could not be obtained, Mr. Morrow is thought to have been unwilling to pose as the representative of the industry when as a matter of fact he was representing only the minority portion of production.

While it is admitted that Mr. Morrow's resignation has precipitated something of a crisis in the affairs of the National Coal Association there is every indication that the organization will continue. It is known that certain coal operators are so convinced of the need of the association that they would be willing to finance it themselves in order to keep it in existence. It is certain that there never has been a time in the history of the coal industry at which so great a need for the organization exists as at present. What the government has done in the way of regulating distribution and in the creation of a commission, which within a year will recommend legislation and other action of great moment to the industry, well may be the entering wedge for drastic federal regulation unless there is evidence that the coal industry is competent to work out its own salvation. With the industry confronting such a situation it is apparent that a point of contact with the federal government will continue to be maintained. It is fully expected that the resignation of Messrs. Morrow and Callahan will emphasize the need for a wider measure of support for the association.

Mr. Morrow first came to the attention of the coal industry in a national way when he wrote the report on coal for the Bureau of the Census, based on the returns of the 1909 census. He was on the point of leaving Washington after the completion of that job when E. N. Hurley was made chairman of the Federal Trade Commission. Mr. Morrow had formerly worked with Mr. Hurley and at his earnest request Mr. Morrow consented to remain to serve as personal assistant to conduct the initial research, which resulted later in the Webb-Pomerene Act, making legal combinations for purposes of export trade. By the time the export investigation was out of the way the coal situation had come in for serious attention, with the result that Mr. Morrow stayed with the commission to make a study of the bituminous-coal industry.

Organized Pittsburgh Producers' Association

Mr. Morrow left the Federal Trade Commission to organize the Pittsburgh Coal Producers' Association. In 1917 he was called to Washington to organize the National Coal Association. In January, 1918, he accepted an invitation from Fuel Administrator Garfield to reorganize the distribution division of that organization. He continued as head of that division until it was dissolved, when he resumed his position with the National Coal Association.

Mr. Callahan began his career in the train service of the Pennsylvania R.R. Promotions carried him into the traffic end of the work, where he specialized in the problems of coal transportation. His activities as traffic manager for the National Coal Association have brought him into the front rank of the country's traffic specialists.

Governer Davis Signs Order Fixing Coal Prices in Ohio at $3.56-$4.86 at Mine

A schedule of fair prices for coal mined in Ohio and sold to Ohio consumers has been formally approved by Governor Harry L. Davis following a week's investigation of the question by State Fuel Administrator Clarence J. Neal. The prices as announced by the administrator are based on those established by the Federal Fuel Administration in 1918. The new price list is to become effective Oct. 10.

The prices as fixed are for mine-run and provisions are made for a charge of 25c. per ton more for lump and 25c. per ton less for screenings and slack. Administrator Neal reports that the price list is to be considered only temporary and will be maintained until a study of the cost of producing and distributing coal now under way is completed, when it is purposed to issue a revised price list. Dealers' and jobbers' prices are likewise to be announced as soon as the necessary information has been compiled. The price list as announced follows:

District No. 1—Meigs County and Cheshire and Addison townships, Gallia County, $4.06.

District No. 2—Vinton Jackson, Lawrence, Scioto, Pike and all of Gallia County, except Cheshire and Addison townships, $4.56.

District No. 3—Hocking and Athens counties, Coal and Monroe townships, in Perry County, and Homer township, Morgan County, $3.75. Bailey Run or No. 7 seam coal, $4.24.

District No. 4—Washington and Noble counties, Morgan County except Homer township and Perry County except Coal and Monroe townships, $4.24.

District No. 5—Muskingum County $3.85.

District No. 6—Holmes, Tuscarawas, Carroll and Coshocton counties; Monroe, Franklin, Washington and Prospect townships in Harrison County; Washington and Yellow Creek townships, Columbiana County, and Brush Creek, Salem, Springfield, Rush and Knox townships, Jefferson County and operations in the 5A vein in Flushing and Union townships, Belmont County, $4.24.

District No. 7—Trumbull, Portage, Summit, Mahoning and Yellow Creek townships, $4.86.

District No. 8—Monroe County, Belmont County except Warren township and operations in the 8A vein in Flushing and Union townships; Washington and Prospect townships, and Jefferson county except Brush Creek, Salem, Rush Knox and Springfield townships, $3.56.

District No. 9—Guernsey County and Warren township in Belmont County, $3.75.

Special prices for coal mined by the Wayne Mining Co., $4.31.

Maryland Householders Balk at Price of Bituminous Coal for Domestic Use

In a communication from the Maryland Fuel Distribution Committee, offering the fullest cooperation to Federal Fuel Distributor Spens, the statement is made that no really acute emergency, as far as soft coal is concerned, exists in that state. The largest users of bituminous coal are said to be able to obtain practically sufficient supplies for their present needs. Dealers are said to be complaining, however, regarding high prices charged at mines for low-volatile bituminous suitable for domestic purposes. The claim is made that these prices are such that, even if slight margins are charged for handling and profit, the price to the consumer makes bituminous coal unattractive for household use. Because of this situation, the committee is experiencing difficulty in persuading Maryland householders to purchase early winter supplies of soft coal to make up for an expected shortage of anthracite during the next few months.

Governor John M. Parker, of Louisiana, states that no acute coal shortage exists in that state, due largely to the extensive use of fuel oil by industrial interests. Conservation measures are, however, being put into effect.

State Fuel Administrator Deprecates Move To Enact Coal Legislation in Michigan

Charles F. Dunn, Fuel Administrator for Wayne County, Michigan, thinks there is no necessity for calling a special session of the Michigan Legislature to regulate prices and distribution of coal in Michigan.

Governor A. J. Groesbeck issued the call Oct. 2, saying that his action was influenced by information from the Federal Fuel Administration that it would be unable to control coal distribution after shipments leave the mines. Governor Groesbeck believes present conditions indicate a serious coal shortage during the winter and he wants to prevent exorbitant prices.

The Detroit Coal Exchange supports the position of Mr. Dunn. One of the officers says Detroit dealers have done no profiteering thus far and would not seek to impose unfair prices on the public. Mr. Dunn, himself a dealer, expresses the hope that he and other dealers will be afforded a hearing before the Legislature or the committee that may be designated to draft the proposed legislation.

Willard Makes Suggestions to Railroads To Speed Up Distribution of Coal

At a conference held with Mr. Spens in Washington on Oct. 3 numerous recommendations for accelerating the distribution of coal throughout the country were unanimously decided upon by the advisory committee on transportation recently appointed by Federal Fuel Distributor C. E. Spens. In a letter to the executive heads of all the railroads, Chairman Willard gives a series of concrete suggestions which cover prompt unloading, discontinuance as far as possible of all maintenance and construction work requiring use of power and cars, use of all available forces to check yards and stations for delayed cars with a view to effecting not only prompt unloading but prompt movement; a vigorous campaign to reduce to the minimum bad-order locomotives and cars; prompt return of foreign coal cars to owners, and advice to coal operators that available coal equipment can be increased to the avoidance of sales that require abnormally long distance movement.

Lake Strike Does Not Halt Flow of Coal

The second week of the strike of sailors employed on the Great Lakes by the Lakes Carriers' Association opened with practically all vessels still on the docks, though the flow of coal over Lake Erie docks was not as heavy as in the previous week. Officials of the sailors' union protested to Secretary Hoover that vessels were leaving port undermanned and that deputy customs collectors refused their request for a muster of the crews of all outbound boats. The customs officers based their refusal on the law which requires the filing of affidavits bearing specific charges against a ship at least six hours before sailing time. They threatened to invoke against the union that clause of the seamen's act which provides a fine of $500 as penalty for the filing of a false affidavit. Ships were cleared in all cases where captains believed their boats to be sufficiently manned.

Locals of District 26 Protest Against New Wage Agreement

Phalen local of the United Mine Workers has formally protested at the wage agreement between the U.M.W. for District 26 (New Brunswick, Nova Scotia and Prince Edward Island) and the soft coal operators, principally the Dominion Coal Co. (British Empire Steel Corporation). This local was instrumental in starting the recent strike which ended in the agreement following the defeat for re-election of the old board of officers including Robert Baxter, president of the district, and Silby Barrett, for twelve years the international board member for the district. The Springhill local also is in the field against the agreement.

The United Mine Workers for District 26 are leading in an attempt to found a labor college. If the college is opened it probably will be built in either Glace Bay or Sydney. The officials of the district assert that such a college is a necessity. The labor college, say the union chiefs, would preserve democracy and instruct in coal mining and other occupations.

DUE TO THE LARGE VOLUME of shipments by river, output of coal and coke in the Connellsville coke region is increasing in spite of the car shortage. All operating mines are increasing in man power and output. A couple of union mines on the river nearby in Washington County struck Oct. 4 — the Diamond mine of the Diamond Coal & Coke Co., because the men were ordered to load cars of the Mather Collieries Co., an open-shop operation, and the Lily mine of the Lily Coal & Coke Co., because they were asked to load barges for the Pittsburgh Steel Co., which operates open-shop mines. The miners tried also to get the Pike mine of the Diamond Coal & Coke Co. out, but failed, and the Diamond mine returned to work Oct. 5.

LOUIS D. TRACY, OF EDGEWOOD, PA., has been appointed superintendent of the central experiment station of the Bureau of Mines at Urbana, Ill. Mr. Tracy was educated at the Sheffield Scientific School and at Yale University. He holds degrees as both mining and civil engineer. He joined the staff of the Bureau of Mines on July 15, 1918. Since that date he has served the bureau continuously as a coal-mining engineer. Mr. Tracy takes the position made vacant by the recent resignation of J. J. Rutledge, who now is chief mining engineer of the Maryland Geological Survey. J. L. Lamson has been transferred from the Geological Survey's New England district to the New York district, with headquarters at Albany. Harry I. Granger was at the same time transferred from Albany to Boston.

REPORTS REACHING WASHINGTON are to the effect that difficulties are being encountered in the burning of the British coal now being imported. The importers contend that this is due to lack of familiarity with the coal, but those who have purchased some of the British coal maintain that poor quality coal has been shipped to America. One of the British cargoes, 7,000 tons, was shipped to Norfolk, which is cited as the latest instance of carrying coals to Newcastle. As this is written, no determination has been reached as to what to do with the shipment.

VERY FEW PERMITS are being issued under Service Order 25. Outside of the Lake movement, only seven permits have been allowed. These cover less than 400 cars. Even these permits are limited to a comparatively small movement.

Mining Congress in Cleveland Is Laying Down National Program for Entire Mining Industry

The American Mining Congress, in session this week at Cleveland, is discussing problems vital to all branches of mining and its affiliated industries with the purpose of laying down a national or even international program for the coming year. The first general aim of the congress is to arouse a protest against "any further encroachment of governmental fraternalism in supervising and restricting individual enterprise in the development of mining." The second is to inaugurate a national policy of industrial co-operation which will help to solve the problem of relations between capital and labor and further eliminate needless waste caused by industrial strife. The third is to advance the cause of standardization in methods, processes and equipment.

The congress opened Monday evening in Cleveland's magnificent Public Auditorium with much formality, including an address by Newton D. Baker, Secretary of War in the Wilson administration and now president of the Cleveland Chamber of Commerce. Tuesday's program provided for a discussion of mining conditions throughout the country. Wednesday morning was devoted to coal. Thursday was to be national standardization day with parallel sessions on industrial co-operation. On Friday, the 13th, metal mining problems are to be foremost. The "silver anniversary banquet" of the congress Friday night is to be the final event of the convention.

All through the convention the program was shaped to eliminate "spread eagleism" and hold every session down to essential facts and matters of real importance to mining. As the convention opened it was predicted that more than 3,000 men who face mining's daily problems would attend and not an hour was to be wasted.

In all its 25 years the congress never met in more beautiful surroundings than in the new auditorium. The main arena or ground floor of the great building provides a floor 247 feet long and 120 feet wide without a post or obstruction of any kind and is illuminated largely through an 80-foot ceiling made mostly of glass. The permanent decorations are in a soft shade of gray with blue in the balcony trim and highlighted in gold. The same colors prevail in Machinery Hall, which is directly below and reached by a winding staircase and several ramps of easy grade.

The exhibits of machinery and equipment are shown artistically in this building. There are about 200 displays of one sort or another, including a demonstration by the Bureau of Mines of new breathing apparatus and other approved appliances, a working model of a Hudson Coal Co. anthracite mine and coal-preparation plant, a state exhibit by Colorado, a small display by the Mexican government and row after row of booths showing the most modern types of mine equipment.

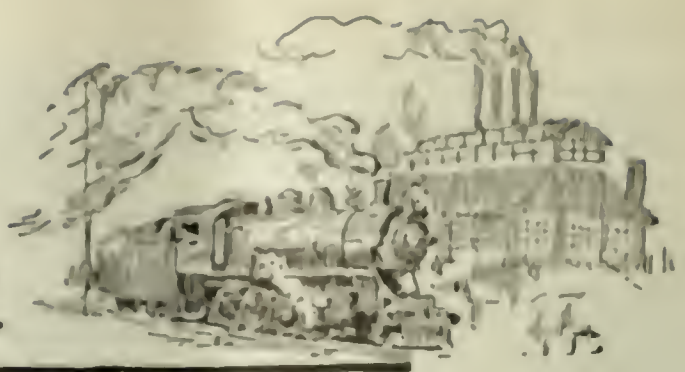
Highlights in the entertainment of the week were the smoker and carnival of Wednesday night, daily organ recitals throughout the convention and much singing by the famous "anthracite sextet" which so often has entertained visitors underground in the Pennsylvania hard-coal region.

Union May Abandon District 29 Because of Partiality of Miners to Open Shop

Abandonment by the United Mine Workers of District 29, which covers the New River field and a small part of the Winding Gulf field, understood to be contemplated by the union organization, is regarded as the logical sequence to developments within the district during the last two years. The proposed relinquishment is due to the fact that there are now so few union miners in the district that a district organization can no longer be supported financially. If District 29 loses its identity as such, it will either be combined with District 17, of which C. F. Keeney is president, or the territory will be looked after by the International organization. The territory in District 29 is now an open-shop territory. By a contract between the operators and miners which became effective Sept. 1, 1920, it became closed-shop territory.

That it has not remained such is due to two factors. In the first place the check-off has never been popular among the miners. That was demonstrated by the opposition to that feature of the Sept. 1, 1919, contract when it was submitted to the miners in a referendum. It was freely stated at the time that a majority of the miners had voted against ratification but that the votes were counted for ratification. The other factor which has led New River operators to adopt the open-shop plan is the frequent strikes and lawlessness displayed by an element among the miners.

When the 1919 contract was agreed to by most of the operators President William McKell and other operators representing about one-tenth of the tonnage of the field refused to become a party thereto and continued to operate on the open-shop plan. Some of the more radical union miners in the district sought to prevent such operation by attacks on McKell plants and did succeed in closing down the Willis Branch Coal Co.'s mine after almost two years of violence. A number of union miners were tried and convicted for such violence and are serving terms in the penitentiary.



No sooner had the operators of the New River field signed the new contract than the men went out on strike on Nov. 1, two months after the new contract became effective. The miners themselves started the move for open-shop operations, early in 1921 asking the operators to resume on a wage scale lower than that of the union. Many of the miners at that time returned to work without any union agreement. Although some of them responded to the strike call of April 1, 1922, mines in the New River field continued at work throughout the strike under the protection of a federal injunction. When an agreement was reached elsewhere by the union no move was made to force the New River field operators to sign an agreement, simply because no sentiment existed among the miners and because they were receiving wages as high as those paid union men without having any agreement or without having to pay money to the union through the check-off.

SEVERAL IGNITIONS OF MINE GAS which might have led to explosions and at least one mine fire attributed to heated leg wires of electric detonators have occurred at mines in which outside shotfiring is practiced. Photographs taken at one mine indicated that the wires became red hot during firing. These results having been called to the attention of the electrical section of the U. S. Bureau of Mines, a series of tests were made at the Pittsburgh (Pa.) experiment station to determine, if possible, the cause of the ignitions and to aid in preventing future trouble of this kind. The investigation, which is considered preliminary, included tests to determine the conditions that cause gas ignitions from heated leg wires of electric detonators, possible remedies for such heating, and the relative behavior of iron and of copper leg wires. Details of these tests are given in Serial 2383, "Ignition of Gas by Electric Detonators," which may be obtained from the Bureau of Mines, Washington.

H. F. BELL, FOREIGN FREIGHT TRAFFIC MANAGER for the Erie Railroad Co., has been given a leave of absence at the request of Fuel Distributor Spens to assist his organization during the existing emergency. Mr. Bell was associated with Mr. Spens in his work for the Railroad Administration and also was one of the traffic staff of the War Industries Board during the war.

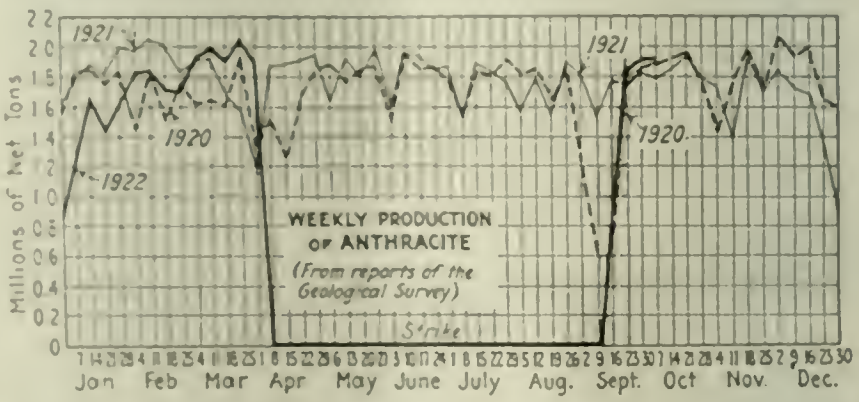
Production and the Market

Weekly Review

Buyers are on a concerted movement to stay out of the market until prices come down. Industrial coal is being sold on a hand-to-mouth basis, for immediate requirements only. Industries throughout the country have responded to the suggestion that business buy coal according to its current needs during the present emergency and the practice is now general.

The effect of the curtailed demand is read in the last two weeks' decline in spot prices of bituminous coal, as shown by Coal Age Index, which stands at 350 on Oct. 5, representing an average spot price at the mine of $4.60. This is a drop of 20c. as compared with the previous week and 66c. below the average price of $5.00 on Sept. 25.

Poor transportation conditions and the growing car shortage tend to modify the price break. Were it not for these factors the present market would range lower all around until the so-called buyers' strike had produced the price level which would tempt the consumer to enter heavier orders.

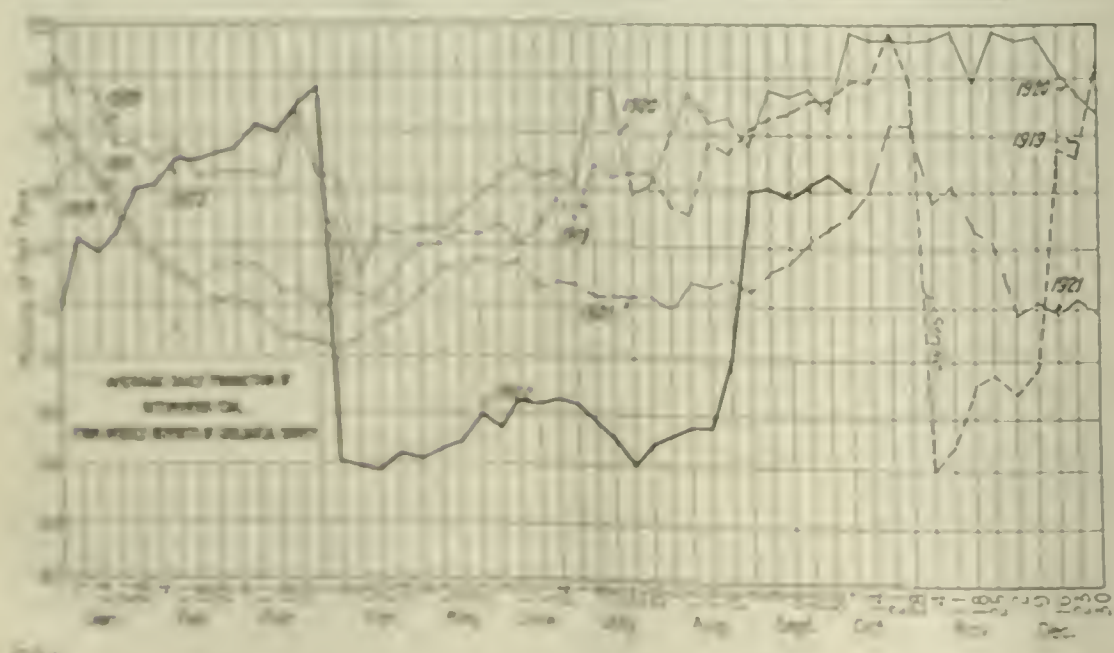


Importance to End Industrial Buyers' Strike

The coal industry has a very definite deficit to overcome before reserve stocks can be brought up to anything like normal. Right now current requirements are absorbing current production, but the approach of coal-burning weather with its attendant transportation difficulties always spells increased demand. If industries call off their buyers' strike and if the railroads give the preference to coal movement that the occasion demands this situation can be met without a reversion to the boom market of two years ago.

Warm weather has reduced the call for domestic coal. Dealers are now having trouble in moving supplies and are inclined to reduce their orders to the mines. Too many people are waiting for household coal to follow steam sizes down in price. The result is producers are feeling the pressure for a reduction on domestic mine prices.

New England is in the heaviest supply of any section of the country and the Northwest, of course, is the shortest. In the former market both all-rail and water-borne fuel is selling off and receipts are dropping. Lake business is very heavy, but the tremendous dock receipts of the past few weeks have so completely dispelled fears of a fuel famine that it has reduced consumer demand and threatens to affect the placing of additional orders at the mines.



The second week of the strike of sailors employed on the Great Lakes shows practically all vessels still

on the move, although dumpings at the lower ports declined in the last week. The sailor's union has protested to Secretary Hoover that vessels were leaving port undermanned.

Breaks in the price of steam sizes of anthracite are reported from several of the larger markets. This is due to oversupply and large producers are running this coal to mine storage. Warm October weather together with the great quantity of soft coal flooding the market has been responsible for a remarkable shrinkage in orders for the smaller coals.

Demand for the larger sizes of hard coal is, of course,

(a) Subject to revision. (b) Revised from last report.

rushing. This market, however, has been affected by the unseasonably warm weather and the inevitable rush to cover has been delayed at a time when dealers welcome every day's respite to enable them to get in more adequate supplies. Mines are handicapped by car shortage and rail delivery is very slow.

BITUMINOUS

"A slight decrease marked production of soft coal during the first week of October," says the Geological Survey. "For three weeks in succession the output had been slowly increasing, reaching 9,776,000 net tons in the week of Sept. 30. During last week (Oct. 2-7) the returns so far received indicate a total of about 9,600,000 tons.

"Although the aggregate shipments of soft coal have increased gradually during September, the shipments from individual producing districts have fluctuated irregularly. In Pennsylvania there was a slight decrease each week since Sept. 9, and last week was begun with shipments at a lower rate than the previous week. In Maryland and part of northern West Virginia there has been a steady increase, but in southern West Virginia there has been a steady decline. In Kentucky there had been little or no change up to last week, for which, however, a decline is indicated. In Alabama daily shipments have been falling off since the close of the first week of September. In Ohio, Indiana and Illinois there have been gradual gains, which now appear to be checked. West of the Mississippi shipments have in the main steadily increased."

New England is the target for heavy tonnage. Western congestion is diverting much coal eastward, forcing it on an unwilling market, with softening quotations. All-rail shippers are pushing sales in an attempt to keep up their production. During the week ended Sept. 30 there were 3,541 cars of soft coal forwarded through the Hudson gateways, as compared with 3,255 in the preceding week.

b Subject to revision.

Westbound coal movement through the "Soo" during September was 2,364,550 net tons. Of this amount only 10,805 tons was hard coal.

Hampton Roads is in oversupply for the same reason and pier tonnage is increasing. Dumpings during the week ended Oct. 5 were 262,945 net tons as compared with 285,635

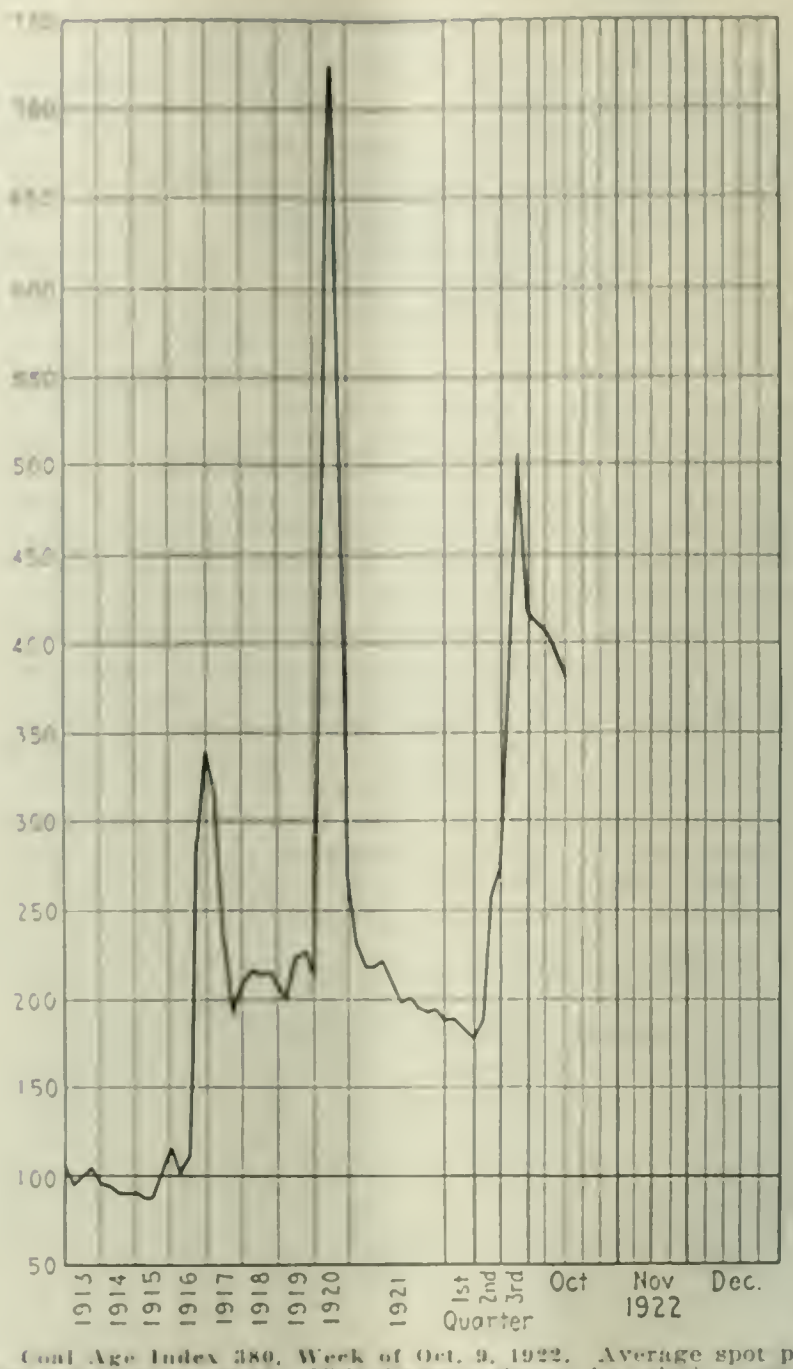
How the Coal Fields Are Working

Car Loadings, Surplusages and Shortages

tons in the previous week. Prices have softened, tempting a slight resumption of exports, but the coastwise market still absorbs most of the coal.

Lake dumpings, which were in unprecedented volume for the last two weeks dropped back to 1,057,266 net tons during the week ended Oct. 9, a falling off of 158,168 tons as

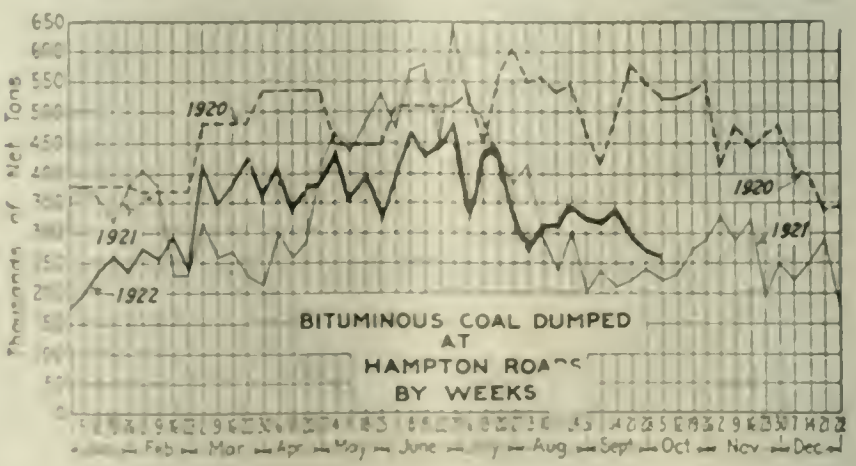
compared with the preceding week. The total Lake movement began to date is 11,276,369 tons; during the corresponding period of last year 15,[illegible] tons had been dumped.



COKE

Pocahontas coke production took a gratifying leap to 162,000 net tons during the week ended Sept. 30, an increase of 29,000 tons as compared with the preceding week. With the exception of West Virginia all districts showed increases. The Connellsville output is the largest since the recovery first started.

Blast furnace coke is as scarce as ever, however, and in general there is not enough tonnage offering to tempt furnaces to operate even if they were willing to pay the going price. There is just enough blister of foundry coke to support the market.



ANTHRACITE

Production of anthracite continues at around 1,300,000 net tons a week. During the week ended Sept. 30 the output was 1,317,000 net tons. Early reports of last week indicated that production will again be around this figure.

Coal Age Index 380, Week of Oct. 9, 1922. Average spot price for same period, $1.60. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions each of slack, prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

Independent prices show a wide range. The family sizes are going as high as $14@$15 in the outlying districts and in Canada, while Eastern centers are paying around $9.50. This is especially true in Philadelphia where high-priced

coal is being little quoted and rarely, if ever, taken. New York market prices have dropped from the high range quoted last week. The steam market has been extremely hard hit by the heavy tonnage and the strong competition of bituminous coal.

Unless coal reaches the bins shortly, the only place many Americans will be warm this winter will be under the collar. —*Indianapolis Star.*

Foreign Market And Export News

British Obtain Orders from Continental Markets; Prices Held Firm

Best British coals continue to strengthen. There is a good demand from Germany, Canada and Italy. The lower grades are more freely offered, however, and with less price firmness. A cable to *Coal Age* places the output during the week ended Sept. 23 at 5,144,000 gross tons as compared with 4,995,000 tons in the preceding week.

Much anxiety is felt over the threat of Welsh miners to give notice to terminate all contracts on Nov. 5, unless the non-union miners join the Miners' Federation.

The outlook in Durham and Northumberland is considerably brighter. The past few days has been marked by a revival of Continental inquiries and orders, which are more welcome than the American orders. The special feature of the European awakening is the interest taken by the Continental gasworks. The European railways are taking more British steam coals, and 150,000 tons have been sold on German account.

The same feature is found in the Yorkshire fields, where the export trade has picked up appreciably. Forward ordering has attained a level which leads the operators to believe that the Continental market is regaining the pre-war standard. Another feature of the Yorkshire area is better business in the home markets.

Coal Freight Rates Reduced in France

French coals from the Nord and Pas-de-Calais area have still a favorable market. There is now quite a rush for domestic. Industrial coals also are in a favorable situation. Gas coals are very scarce.

On the other hand, the situation of the minor fields of the center of France, which are feeling the pinch of the competition of Lorraine and Sarre coals, is far from being as satisfactory and more small mines are closing.

The various reductions on rail rates for coal from the Nord and Pas-de-Calais have been approved by the French Minister of Public Works for a provisional period of three months from Sept. 20. These are deemed insufficient by French collieries, all the more so as they are offset by a similar reduction granted on the transportation of Sarre and Lorraine coals.

No progress is to be reported in the conflict between operators and men, but a general strike of miners about the middle of October is not at all impossible. Mines of the Nord and Pas-de-Calais are said to be already preparing for it by slackening down their shipments.

Representatives of the Swiss Federal Railways are now negotiating with French reconstructed collieries for a briquet contract.

Other countries	719	5,464
Total	870,332	$4,517,479

Hampton Roads Market is Weaker

The market was dull last week, a slight movement in export business proving the only redeeming feature. For the first time in many months the piers reported only about 10,000 tons of vessels waiting for cargo. Prospects for increased movement in the immediate future were very slight.

Prices continue downward, and shippers express the hope they might drop far enough to permit a stronger movement of export coal. Large stocks are on hand at the piers.

Coal Paragraphs from Foreign Lands

ITALY—The price of Cardiff steam first is quoted at 39s. 6d., according to a cable to *Coal Age*.

AUSTRIA.—The output of coal and lignite during the first half of 1922 was 1,674,000 tons; a falling off in the second quarter (810,000 against 864,000 tons in the first) due to serious labor troubles.

INDIA—The tendency of the coal market is weaker. Supplies are adequate. Mills and railways are not in the market and quotations are unchanged.

BELGIUM—The market is very firm, both in the domestic and industrial sections. Briquets are in great demand for home consumption and for export.

GERMANY—Production in the Ruhr region during the week ended Sept. 24 was 1,892,000 metric tons, according to a cable to *Coal Age*, as compared with 1,847,000 tons in the preceding week.

Heavier Offerings in East With Western Railway Jam

Embargoes and Shipping Conditions Complicate Situation—Average Consumer Still Banks on Price Decline, Deaf to Warning of Shortage—Railroads Buying Heavily

Coal congestion in the West has thrown heavier offerings eastward. The movement is very slow, as there are many embargoes and shipping conditions are becoming more complicated each day. British coal continues to arrive, but in smaller volume.

Prices are dropping slowly and each decline reassures the average consumer of the wisdom of his buying policy. He is deaf to warnings of a shortage to come and maintains his attitude of aloofness, covering only at current requirements. Railroads, however, are taking heavy tonnages, assigning so many cars for this business that the supply for loading commercial coal is very meager.

There is almost no inquiry at Tidewater. Line shipments are slow in getting through from the mines and sellers are devoting much of their attention to tracing cars to destination.

PHILADELPHIA

There is a lack of market activity, efforts of the shipping people being confined mostly to endeavoring to get coal on the road forwarded to destination. The consumer for the most part continues in his aloofness, and when he does make purchases is very much inclined to shop around.

The producer is not doing a great deal of urging of tonnage on customers, as he has very little free coal anyway, and the consumer is somewhat resentful when spread prices are not at his level.

There are so many freight embargoes of various kinds in effect that shippers are unable to keep track of them, and in the meantime are unable to get sufficient cars to keep their mines to capacity. One shipper interviewed stated that on a single day last week on an allotment of 50 cars he received 3 and declared this is typical of his operations on both the Pennsylvania and B. & O. Prices have rounded, and with each slight drop the consumer points out that his level will be reached before long.

This week there was probably an average recession of 25c. a ton all around, and yet at these prices more than one producer claims to be digging coal at a loss, due to his curtailed output.

Railroads are endeavoring to accommodate, yet as assigned car orders may have been unable to deliver sufficient cars to all roads to meet their requirements. The prices they are willing to pay for low-volatile coal is around $4, and for high-volatile, $3.25.

BALTIMORE

A curious trend has arisen in the local situation for, whereas car supply is stretched and demand as compared with the light deliveries seems fairly good, there is a softening of the price list. Some of the producing interests report that they are maintaining the price list that has been set for a couple of weeks past, but there are undoubtedly cuts of considerable nature from the hands of other large producers and this has lowered the general average of sales.

The fact that there is not much Pool 9 on the market has held that a little better than is the case with Pools 10 and 11, wherein the principal drop has come. Car supply is the most serious feature of present conditions. On some days the B. & O. run of empties to mines falls below 20 per cent. The movement of British coals to Baltimore continues heavy and there is ready absorption so far for what has come in.

NEW YORK

There is practically no inquiry at Tidewater, but line demand is more active. Buyers are not anxious to step up although inducements in the way of lower prices might be offered. Arguments, such as a shortage of cars, are being employed but to no avail. Some consumers look for much lower prices than the present.

With production running at its present level consumers believe there will be further breaks and notwithstanding the lack of cars they will be able to get all the coal needed. Another reason for the lack of demand was the removal of restrictions.

There were close to 1,300 cars at the local piers on Oct. 6. In addition there was considerable British coal to be had at from $6.75@$7 alongside.

Receipts of British coal are growing smaller. With the "fixing" of three Shipping Board vessels this week it is believed they will be among the last. During the week nine vessels, carrying a trifle more than 58,000 tons, arrived here.

Efforts are being made to have the restrictions against bunkering removed, it being contended that within the next 30 days conditions will be normal.

Quotations on some grades, especially Pool No. 9, show a wide range. Punxsutawney and P. R.R. high-volatiles were held around $4; gas, run of mine, around $4.75, gas lump 75c. higher. Bituminous coals were quoted close to $3.50.

CENTRAL PENNSYLVANIA

Operators have gotten their stride and during the month of September produced 76,509 cars. September, 1919, had a production of 90,527 cars, while September, 1920, produced 91,015 carloads. In August this year, the production was 50,364, while in July the total was 14,076 carloads.

The car shortage, particularly in the western part of the district, continues quite aggravating. Prices remain stable, Pool 11 being quoted at $4 and Pool 1 at $5@$5.50.

UPPER POTOMAC

For the first time in several months there was a car shortage in evidence on the line of the Western Maryland in the Potomac field. The curtailed supply of reduced production at a time when the rate of output was about 60,000 tons a week or not far from normal. The curtailed supply of empties, however, found mines with less of a demand to meet owing to the large tonnage in Eastern markets, the effect of which has been to reduce prices.

FAIRMONT

Industrial demand was at rather a low ebb during the closing week of September. This was attributed to the large volume of coal pouring into Eastern markets as Western shipments were embargoed, even to the Lakes, at times. The car supply is becoming more and more restricted. The only mines having cars to amount to anything were those having railroad fuel orders. Operators complain that the Baltimore and Ohio is assigning cars once again and that it is next to impossible to secure equipment for commercial loading.

South

BIRMINGHAM

The problem of the trade continues to be one of car supply. The quota furnished the past week ranged from 30 to 40 per cent of the number needed, and the prospects of any material improvement in the near future are not bright. Much of the equipment of local carriers found its way into foreign territory during the period of shortage caused by the strike and has never been returned to the owners.

There is a strong and urgent domestic demand from every direction. Dealers with contracts are not receiving their quota by any means, due to car shortage. The easing off in the demand for steam coal is also affecting the supply.

Quotations are remaining fairly stable on steam grades though some seams have been selling 25c.@$35c. under the maximum schedule the past week.

The output is holding up well considering the acute car shortage, a total of 345,000 net tons being reported for the week ended Sept. 23, the last figures available. The week of Sept. 30 will probably show a decrease, as transportation conditions were not so favorable.

VIRGINIA

So far mines have not been able to overcome the handicap of a car shortage which is curtailing production to the extent of 50 per cent. It is not so much the strike of shopmen as it is the fact that few of the roads are able to put their hands on enough equipment to keep the mines supplied. The demand for coal is weaker with the result that prices have softened somewhat.

Anthracite

Rush in Domestic Business, Steam Sizes Drug on Market

New York Harbor Terminals Clogged with Commercial Coal, Which May Affect Fuel Situation—Warm Weather Prevents Scramble in Portioning Out of Household Coal.

New York harbor terminals are heavily congested with steam loads of anthracite. Railroad officials fear that the tying up of these cars will seriously affect the fuel situation at New York. Steam sizes quickly became a drug on the market following the resumption of mining, and those producers who have such facilities are now storing these grades.

Domestic business is, of course, rushing. Coal is being portioned out to consumers in small lots and the unseasonably warm weather has fortunately delayed the inevitable rush of householders. Independent quotation show a wide range but the extremely high-priced coal is going to small towns or Canadian points, as Eastern distributing factors are loath to pass on these premiums to their customers.

NEW YORK

Lack of demand has resulted in an accumulation of steam coals here. At the end of the week there were about 3,500 cars containing upward of 175,000 tons at the various railroad terminals adjacent to the New York harbor.

Because of the failure of consumers to take this coal the larger mining companies have reduced the output of these sizes by closing down various washeries and are again storing the present production. That there should be an oversupply at this time is attributed to the supply of bituminous.

Dealers predict that unless the weather becomes unusually colder during the next four weeks and with production continuing at or about the same basis as at present, the situation will be comparatively easy. In the West, however, users of anthracite will be forced to take soft coal.

Quotations for independent domestic coals cover a wide range starting at $9.25, most of the big operators going as high as $9.50.

PHILADELPHIA

Moderate shipments to retailers are coming in and as a result deliveries to consumers are going along quietly. The remarkable run of warm weather has tempered the demand considerably.

There is much speculation as to the relative scarcity of pea, as most dealers had an idea it would be plentiful. Numerous dealers have put in requests urging prompt delivery of this size, probably not with the idea of moving it at once, but to get some stock ahead.

Retail prices are unchanged. Wholesale quotations show no appreciable change in the last week. Independent prices higher than $9.50 are heard repeatedly, but sales are rare.

The State Fuel Commission is hearing the arguments of independent shippers to establish their right to get more than $8.50. It is likely the present prices will be approved in all cases, and in a few instances even higher figures will be allowed later.

Steam sizes are moving along nicely, although there is just the slightest tendency for a slowing down on rice, but all shippers are easily able to get full prices. Some retailers are taking a small tonnage of buckwheat, generally at the urging of the shippers.

BUFFALO

Demand is rushing. It would be impossible for a while to satisfy the consumers with five times the ordinary supply.

The independent mines are trying to ask from $12 up, but jobbers are afraid to buy, because they have to report their sales to the fuel administrator and the prices they have to ask look bad. It will be a long time before the trade is easy.

The effort of the Lake seamen to tie up the fleet by a strike appears to have failed. The steamers move as usual. The west-bound coal movement is light. Shipments to date since the beginning on Sept. 23 have been only 91,600 tons, of which 46,600 tons cleared for Milwaukee, 31,300 tons for Duluth and Superior, 13,700 tons for Chicago and 7,700 tons for Sheboygan. Rates are 40c. to Duluth, 50c. to Milwaukee, Sheboygan and 50c.@55c. to Chicago.

BOSTON

Shipments are coming forward steadily. There are large retail distributors who have not yet had cargoes of prepared sizes, but there seems less anxiety than a fortnight ago. The unseasonably warm weather has delayed the on-coming rush, but in another fortnight there will be heavy pressure on all the anthracite channels to provide increasing supplies.

No change has yet been made in retail prices. What coal is being passed out is at figures that prevailed during the spring, except in pea sizes which is either sold mixed with other sizes or commands a price on an equality with them.

BALTIMORE

Receipts are light and dealers are sticking to their resolve to deliver not more than one or two tons to a customer. Additional receipts are expected as a result of the announcement of the B. & O. of a new freight rate of $3.28 on coal from the Schuylkill field of Pennsylvania. This rate was arranged by agreement with the P. & R. and the L. & N. E. railroads. The B. & O. will carry coal from the Schuylkill field at the same rate charged by the Pennsylvania for coal from the field which they tap.

The Maryland Distribution Committee has taken up with Pennsylvania producers the question of supplying peck and bushel men in this city who claim that they are unable to get any coal whatsoever. It is planned to work out some measure by which the poor of the city who buy in bushel and peck lots will be able to get supplies.

Coke

CONNELLSVILLE

Connellsville coke remains as scarce as ever and prices on an average are a shade above those of a week ago, with furnace at $12@$12.50 and foundry at $13.50@$14. An additional furnace has resumed on coke bought in the open market, a second Shenango stack, while Struthers furnace blew in Oct. 7 on coke obtained through an old contract. In general there is not enough coke in the open market to enable any furnaces to resume by simply buying coke, while most furnaces would probably hesitate to pay present prices even if they were sure of getting a steady supply.

Consumers have shown such an indisposition to pay present pig iron prices that furnaces are not as disposed to get into blast as might be supposed from a mere comparison of coke and pig iron prices.

There is a good bit of inquiry for foundry coke, but the majority of foundries seem unwilling to pay present prices. Enough are willing to buy to support the market at its present level, with offerings relatively limited.

The *Courier* reports production during the week ended Sept. 30, at 90,250 tons by the furnace ovens, and 28,430 tons by the merchant ovens, a total of 118,680 tons, an increase of 13,340 tons.

UNIONTOWN

Despite an acute car shortage coal prices have slipped off several notches, with $3.25@$3.50 prevailing and probably sales made at lower figures. Brokers and operators report difficulty in finding destination for large shipments but encounter very little trouble in placing small lots. That would infer that buyers have placed their coal requirements upon a hand-to-mouth basis.

That the union intends continuing its fight in the Connellsville region seems indicated by the erection of barracks at the Leisenring plants to house evicted miners who are now living in tents. At both Uniontown and Connellsville there are evicted families living with other families. At Uniontown health authorities ordered a dozen families out of an old warehouse because of health conditions as well as the menace of fire. Many of the families are reported to be in dire straits and the drift back to the mines has increased.

BUFFALO

Demand is light, but the supply is so small that high prices are generally maintained. But for the fact that we have a good line of by-product ovens the prices of beehive coke would soar still more.

Chicago and Midwest

Bottom Softens Under Midwest Coal Trade

Even Domestic Demand, Which Has Been Strong, Is Weakening—Steam Prices Sag Lower—Rail Service Continues Bad—Cold Snap Desired.

The entire Midwest is getting deeper and deeper in the "grumps." Warm weather, reports of increasingly heavy car loadings in the Eastern fields and news of mine-operative peace have combined to rob the trade of its one bolstering feature, strong domestic demand. Dealers are now having trouble in moving household coal. The result is that producers are having difficulty in keeping out of the red and the pressure for a reduction in domestic mine prices is becoming insistent. The steam buyers' strike of big consumers is still determinedly pulling screenings prices lower and lower.

Rail service is generally worse. Cops are hogging most of the motive power. It cannot be said that the mines are so urgently requesting cars in most fields. Those properties holding heavy contracts are the only ones that could use a 50 per cent car supply if they could get it and even contract business is none too dependable under present conditions.

All Illinois fields are shut down five days each week, averaging for the state around 30 per cent. Indiana is similarly situated. Western Kentucky is finding a slightly better market, especially in the South. What is really needed is some good cold weather that will bolster the domestic trade as well as aid the steam situation.

CHICAGO

With continued unseasonably warm weather and an exceedingly short car supply, the coal market is undergoing a severe strain. From every branch of the business come reports that very little buying is being done. The strong demand which has kept the domestic business alive has at last shown signs of softening. Mines all state that running time is getting worse.

In several instances domestic orders have been cancelled, which would be considered unusual at this time of the year.

There is practically no spot market for screenings, as steam buyers continue to stay out of the market.

Local brokers are announcing that they are handling no spot Pocahontas at all. Their time is largely taken up with trying to get coal enough to take care of their contract business. They report some improvement in rail conditions with the past few days; however, they are doubtful if any appreciable spot market will develop for some time.

WESTERN KENTUCKY

Steam coal prices slumped off during the week considerably, and some screenings are now quoted as low as $3, although the market ranges as high as $3.75, along with mine run which is quoted $2.50@$2.75. Lump is strong at $5@$5.50, and if any sales have been made at under the $5 figure the past few days, the operators are keeping it to themselves.

Although reports have been heard from Illinois and other points of screenings being in such small demand that operators have been dumping them at any price in order to load out lump, there is no dumping of screenings in western Kentucky, where car supply is probably as bad as anywhere in the country. With lump at $5 and up and screenings at $3 and up, the mine run price is something over $4.

Demand is principally from Southern cities, as Chicago and long-haul points are being offered plenty of coal from other districts, and with the present small car supply operators do not need more business and are not forced to cut prices. Demand for lump is better.

LOUISVILLE

According to some well-posted coal men a demand for domestic fuel is going to hit soon when the weather turns cold, which will make the price waiters mighty sick. Some operators claim there is a "buyers strike" of domestic and industrial consumers. This does not check with reports of operators who say they are loading out all the coal they can get cars for. As a matter of fact buyers are not bidding up prices, therefore operators are talking of the "strike."

Retailers are willing to buy lump and even stock it at a reasonable price, but not at $5 and up. As a result production is principally on mine run, and this is moving out as fast as roads can supply cars.

Lake movement, along with steel plant, gas, byproduct and utility demand on eastern Kentucky, is not hampering production any considering a car supply reported at about 20 per cent. Gas coal is carrying a premium over steam, it being quoted $5@$5.75 for best mine run, whereas non-gas is $4.25 @$5, with some low grade at $4.

SOUTHERN ILLINOIS

The movement of cars in the Carterville field has shown up some better the past week but the shortage seems to increase. A record check at one mine on the Missouri Pacific the past week showed 7 per cent equipment furnished, on the Burlington 13 per cent and on the Illinois Central 15 per cent. These figures are taken from mines having all three roads. It would check about 25 per cent car supply. Steam sizes are heavy and several mines have screenings and small sizes unbilled. This situation is depressing and is accounted for by warm weather. A somewhat similar condition exists in the Duquoin and Jackson County field.

In the Mt. Olive district there is considerable trouble moving steam coal. Domestic sizes are not moving freely on account of hopper bottom equipment which the dealers cannot unload. In this particular field the return movement of empty cars is not good, although about a 2- or 3-day car supply is furnished.

In the Standard district steam sizes are holding up everything on account of their inability to move and this will likely continue for some time unless severe weather sets in. The market seems to be weakening and some mines have so many "no bill" steam sizes that many roads are refusing to furnish any more equipment until the loads are moved.

ST. LOUIS

Warm weather and an indifferent public have brought the local market to the point of demoralization. Orders are coming in for small quantities but earlier orders are cancelled in the hope of warm weather and a slump of domestic coal along with steam sizes. The local steam trade is lagging, figuring on buying cheaper coal. This attitude is forcing the market rapidly. Many St. Louis steam plants are still using oil. Oil competition has been felt all over the Midwest. Again, there is another April 1 not far off that the steam trade fears. In St. Louis recently the Scullin Steel Co., United Railways and City Waterworks quit oil for coal. In East St. Louis and Granite City coal to the tonnage daily of about 20 to 30 cars has recently supplanted oil. But the Frisco will have all of its divisions using oil except the River and Cape between St. Louis and Memphis and the Alabama division between Memphis and Birmingham by April 1, 1924. This will throw out between 3,000 and 4,000 tons of coal daily.

Both country domestic and steam trades have been good up to the present but have followed the action of the St. Louis dealers quickly in curtailing shipments. A little snappy weather will brighten things up. There is no anthracite to speak of coming in and no smokeless. Coke production is light and the condition generally is far from satisfactory.

INDIANAPOLIS

Although the coal situation has not changed within the last few days and prices have held steady, some coal men believe a break in prices will come soon. The demand is not strong and retail dealers say they are having no difficulty in getting sufficient tonnage to supply the domestic market. Dealers are not getting enough to stock, however. It is doubtful if they would at present prices anyway.

The weekly statement of the Indiana Retail Coal Merchants' Association said: "While it is believed the general trend of mine prices will be downward, there is nothing at present to indicate that there will be any change in the price of domestic coal soon. Steam is off, due to an alleged buying strike on the part of large industrial consumers.

Eastern Inland

More Pressing Need of Coal Gives Market Better Tone

While Buyers Seem to Seek Only Current Needs There Are More of Them —Ohio Price Schedule Causes Shippers to Force Lake Markets—Lake Dumpings Still Heavy—Pittsburgh Market Dull.

There is a slightly better market tone. Under pressure of growing coal needs and more firmly held prices industries are showing signs of interest. There is no snap to the market but it has lost some of its apathetic tone of the last few weeks. The general policy has been to buy for current needs only, but more of such takers are in the market.

Governor Davis' announcement of the temporary Ohio fair price list has caused some operators to say that if it is enforced they must send their product out of the state, where higher figures can be obtained. The establishment of these prices is causing shippers to force the Lake market, which is paying $4.25 for good No. 8, as compared with Ohio's list of $3.56.

Lake dumpings are still heavy, although rail congestion is reducing the movement somewhat. Vessels are clearing quickly and but little effect of the Lake seamens' strike has been felt as yet. Dumpings at the lower ports during the week ended Oct. 9 were 1,087,265 net tons, as compared with 1,245,373 tons in the preceding week.

The Pittsburgh market is still distinctly dull. Consumer requirements seem to have been over-estimated. However, the sluggish market is not a factor in controlling the output as yet, as cars are far too scarce to permit prompt loading of the orders in hand.

PITTSBURGH

Demand has fallen off in marked fashion and the market is commonly described as being distinctly dull. Prices have declined 25c.@50c., but are now practically stationary.

All told, consumptive requirements do not seem to be as heavy as was predicted. The average buyer is quite content to cover his immediate requirements, showing no disposition to buy even for a short time ahead. Demand from retail dealers is fair, but seems to be for current distribution only, the dealers being unwilling to put in any stocks. Truck mines are still doing considerable business in domestic fuel and in some cases are making prices well below what can be done on rail coal.

Production is not affected by the dull market as prices still show a wide margin. The limiting factor in production is car supply, which is hardly as good as 30 days ago and is of course far below mine capacity.

The market is quotable at $3.50@$3.75 for good grades of steam coal, $4.50 for byproduct, $4.50@$4.75 for good gas, all mine run, and $5.25@$5.50 for best grades of domestic 1¼-in. lump.

BUFFALO

Shippers are urging consumers to buy, pointing to the fast-growing shortage of cars, but the advice is not much heeded. The talk is called mere effort to work off coal. So the prices weaken and the more they go down the more the consumers refuse to buy. The movement is declared to be less than consumption, but the consumer does not mind that, so long as he believes that he is pounding down the price. The decline is not likely to last. In fact, the shipper is unable to see how the opposite is not the case. One thing is doubtless overlooked. The natural production is large and somebody is managing to get his coal to destination.

As to prices there is naturally a wide range. Some shippers manage to get as high as $6.50 at the mines for gas or Pittsburgh lump and some mines are offering good coal below $4. A fair average is $4.50 for Allegheny Valley mine run and $5@$5.25 for Pittsburgh lump, with a little more for gas lump. The freight to be added for Buffalo delivery is $2.09 for Allegheny Valley and $2.24 for Pittsburgh.

CLEVELAND

A slightly better tone in the market is reported. There is nothing resembling activity, but operators and dealers are somewhat encouraged by what they believe is a growing disposition of buyers to come into the market at prevailing prices. For some weeks consumers have been holding out for lower levels.

Under the pressure of growing coal needs, and with the price showing no further evidence of important declines, industries are giving indications of buying. The state fuel commission has announced the official scale of "fixed" prices. The level of $3.56 for No. 8 mine run is regarded by most operators as unreasonably low. Since there is a fairly good market for this in the Lake trade at $4.25, as much coal as possible will be sent out of the state. The shortage of cars is becoming more and more pronounced in this district. Current quotations are shown in the Weekly Review.

The Lake movement continues at high speed, apparently undisturbed by the walk-out of the union seamen. It is now believed that it will be possible to ship the Northwest more than 15,000,000 tons, which was regarded as the limit a month or so ago. Fears of shortage in the Northwest are greatly diminished and there is no panic of buyers apparent.

NORTHERN PANHANDLE

Accumulation at the Lakes constitutes the most serious interference with the movement and is having a tendency to check production. Although there is not quite so strong a demand for steam coals, nevertheless more coal could be moved if the transportation situation permitted but termnials are clogged with cars. There is more of a demand for lump than any other grade.

COLUMBUS

While the "buyers strike" is not over, still there is evidence of a disposition to buy. Lake shipments are going forward, many embargoes having been removed.

Householders are coming into the market more and more, but the continued warm weather is still delaying them. Retail prices are rather steady at former levels, with Hocking lump, $8.75@$9.50 and smokeless grades up to $11.

The Pennsylvania has removed its Lake embargo and the same is true of other Lake-carrying roads. The New York Central is still badly involved and little coal is going through on either the K. & M. or the T. & O. C. H. V. Ry., shipments are not interfered with.

DETROIT

Not very much interest is being manifested in the market. Summerlike temperatures during the week have soothed the household consumers into lethargic indifference. Detroit's receipts are still far below the amount which dealers estimate as the city's average daily consumption.

A theory advanced by some that the strike of the sailors' union of the Great Lakes against the Lake Carriers' Association effective since Oct. 1, would so handicap the shipping interests as to reduce coal loading and increase the quantity available for shipment to Detroit, has not developed into actuality, as the boats of the Lake Carriers' Association are being maintained in operation, apparently unobstructed by the strike and the volume of coal loaded last week approximates 1,000,000 tons.

The larger part of the present supply is coming from mines in Ohio. Hocking lump and egg is quoted at $8, mine run, $3.75@$4, mine, run and slack, $3.25@$3.50. Pittsburgh No. 8 3-in. lump is $5, mine run, $4@$4.25, slack, $3@$3.75. Fairmont 3-in. lump is $5, mine run, $4.50@$4.75, slack, $4.50. Smokeless lump and egg holds around $8.50, with mine run $6.50@$6.75. West Virginia and Kentucky lump and egg is $6.25@$6.50, mine run, $4.75, slack, $4.50@$4.75.

Anthracite is arriving in small amount. Jobbers are receiving independent quotations of $12@$14 at the mines. The freight charge is $4.06, making the retail price very high.

Northwest

No Fear of Famine in Upper Lake States

Shipments Receipts So Heavy During Recent Weeks and Demand So Light That Docks May Stop Shipments—Hard-Coal Cargoes Also Arrive.

The Northwest is experiencing another "spell" in its spotted pre-winter season. Its fear of a fuel famine has been so completely dispelled by tremendously heavy cargo receipts recently that it has forgotten the scarcity it saw in August. This has reduced consumer demand and coal is now piling up on the docks. Dock men are about to curtail orders lest they be caught this winter with too much surplus, secured at high prices just at the time that all-rail competition is to be expected. It appears that only a cold snap will remedy this peculiar situation.

Even anthracite is beginning to come in small lots. At Milwaukee the old prices prevail but at the Head-of-the-Lakes, where less tonnage has penetrated, it is expected the price will be higher.

MINNEAPOLIS

The Northwest's fear of a coal famine is about gone. It now appears evident that enough fuel will have arrived in the zone of navigation to prevent any suffering. The coal trade reported that it could handle the situation if it could be assured of transportation. And the tonnage moved during September and the early part of October seems to justify this claim.

It will be only a short time, with the heavy tonnage moving until the dock companies will begin to reduce receipts that they may not be overstocked. For it is possible—even likely—that there will be keen competition from the all-rail fields. Another factor which will enter into the coal final tonnage of the Northwest is the ignite of North Dakota. Production there will be sharply increased for the winter.

There have been some instances of Dakotans dealers selling inferior coal at high prices, which resulted in complaint but the rank and file of regular dealers have kept their prices in line with their costs.

MILWAUKEE

October brought a little comfort to hard-coal consumers in the shape of several cargoes. This coal is being sold at the old figures, namely $15.75 for egg, $16 for nut, $14 for pea, and $11.50 for buckwheat.

An advance was made in screened Pocahontas, however. The retail price of this is now $14.75 and the wholesale price $13.25. Mine run is still sold at $9.75 wholesale, and $11.25 retail. Pittsburgh, Hocking and Youghiogheny were reduced 50c. or to $9.75 wholesale, and $11.25 retail. Pile run and screenings were cut 75c., the wholesale price of both sizes now being $9. Other grades of soft coal remain unchanged. Hocking coal is down to $7.50, the lowest it has been for some time.

The danger of a fuel shortage is now rapidly dissipated by heavy receipts. It is evident, however, that many hard-coal consumers will have to turn to soft coal. There is some talk of rationing the anthracite as it arrives. Thus far in October, 20 cargoes have been docked, aggregating 72,400 tons of anthracite, and 150,353 tons of soft coal.

September cargo receipts aggregated 43,343 tons of soft coal, making the receipts of cargo coal for the season 709 tons of anthracite, and 1,290,955 tons of soft coal. During the same period car-ferries brought 20,794 tons of anthracite, and 77,633 tons of soft coal. Rail receipts aggregated 50 tons of anthracite, and 162,746 tons of soft coal, making the grand total of hard and soft coal from all sources since the season of navigation opened up to Oct. 1, 1,746,878 tons.

DULUTH

Unofficial reports place receipts of bituminous at the Head-of-the-Lakes at 1,500,000 tons during September. This indicates there will be opportunity to bring up enough coal if shipments continue. But dock men here may order a halt. Coal has commenced to accumulate on the docks because large consumers are not laying in supplies or making contracts. Dock men claim that last year they lost nearly $500,000 through depreciation of large stocks carried over the winter.

Consumers are frankly waiting for a drop in prices. Youghiogheny and Splint are quoted at $9.50 for lump, $9 for run of pile and $7.50 for screenings. Hocking is 25c. off for lump and run of pile and 50c. off for screenings. The market on Hocking screenings is long. Dock men say that there will be no further reductions.

The seamen's strike has had no visible effect on the movement of ships. At this port few leave the ships, but those who do are replaced easily. The same situation exists at lower ports, according to press reports.

The volume of receipts holds up. Last week 48 cargoes were received of which one was anthracite—the first since the strike started. Twenty-four are reported on the way, of which two are hard coal. Hard coal shipments may increase materially soon. No prices have been made as yet on anthracite, but they are expected to be above last year's level.

New England

Heavy Reserves Postpone Big Buying Till January

Large Volume of British and Southern Coals Depresses Market—Receipts Ahead of Same Period Last Year—Consumption Lower—Prices Drop.

There is very little buying power left in the current market. The avalanche of British coal, together with heavier receipts of Southern coals, has increased reserves to so great an extent that there is hardly a chance of any comprehensive purchasing before January. Throughout this territory receipts have been much larger thus far this year than during the same period in 1921, while consumption has been notably less. It is very difficult to see, therefore, how there can be any improvement in trade conditions the next 30 to 60 days.

Prices are materially lower. Hampton Roads accumulations have reached 150,000 tons and receipts of Pennsylvania coals are declining with the market.

This week prices have slumped all along the line. From a $9.15 asking price on cars Boston for Inland delivery the spot market has eased off already to $8.50 and less. At Hampton Roads $7.35 has been quoted, with intimations that $7 per gross ton f.o.b. vessel would be acceptable. In other words, the so-called Hoover fair price is now bettered by a full dollar a ton.

At Newport News and Norfolk the accumulation of coal over and above bottoms is increasing perceptibly day by day. While there are a few consumers here and there who have faith in a very short car-supply later on, the majority of buyers show no present interest in the spot market.

All the Pennsylvania grades are in most plentiful supply. All-rail receipts, however, are beginning to decline with the weakening market. From $5.25 per net ton for fair grades the average figure has now dropped to $4. Even the choicest quality coals on the Navy Acceptable list can now be had at $4.50@$4.75. More than a few operators are faced with the necessity either of closing their mines or accepting much lower prices even than those now ruling.

Among wholesalers opinion seems still to be divided between those who feel that short car-supply will induce buying and those who say that even with equipment reduced, say to 50@60 per cent normal, the great bulk of central Pennsylvania output will be seeking buyers at less than currrent spot quotations. Meanwhile, the buyers themselves are in an attitude of "watchful waiting."

Cincinnati Gateway

Trade Watches Prices in Other Producing Fields

As Quotations Recede and Rejections Increase, Byproduct, Gas and Domestic Coals Are Market Bulwarks—Some Still Base Hopes on Car Shortage.

With quotations slipping a bit more rapidly, rejections increasing in volume and reports piling up of Northern terminals being clogged with coal—the first time that such a situation has obtained since last April—it can well be said that byproduct, gas and domestic coals are the mainstays of the market at this writing.

Lake buying has temporarily ceased and with this highly competitive feature playing little part in the bidding for coal and on top of this many buyers discriminating against shipments that will not come up to grade, the trade has been looking about and there has been a disposition to keep a weather eye on what other producing fields are doing in the way of naming prices. Those jobbers and wholesalers who believe that the cream can be skimmed forever are still holding tight to their estimates based upon a scant supply of empty cars, but this feature can no longer be taken as a barometer.

LOW-VOLATILE FIELDS

New River and the Gulf

Buyers are trying to maintain control of the market by declining to buy until prices reach a lower level but are unable to dominate the situation as much in the West as in the East, according to conditions reflected in the New River field. The continued shortage of cars is preventing more of a break in prices. Most of the coal has been moving to the coast, since it is difficult to get smokeless through to Western markets where there is a strong demand for prepared sizes. The car supply is not averaging over 30 per cent.

Winding Gulf mines were greatly hampered during the final week of September by the extremely poor car supply. It was not possible to produce more than 100,000 tons representing less than 40 per cent of capacity. Even under normal conditions little coal from this region moves westward and now that these lines are congested less tonnage than ever is going west. Tide water is soft owing to the large volume of receipts.

Pocahontas and Tug River

Pocahontas coal is being diverted to Tidewater and the East, the Pennsylvania and the Hocking having imposed an embargo on coal originating in the Pocahontas region owing to conditions at Lake piers. The car supply is holding back production to a material extent. The greatest difficulty is in getting empties back from Western lines, much equipment being under load at the Lakes.

Tug River mines are not producing more than 75,000 tons a week owing chiefly to a poor car supply. Buyers are showing a disposition to remain aloof from the market and to "bear" prices but a poor car supply is modifying the downward pressure.

CINCINNATI

So many mines are pouring out mine run with little or no attention to preparation that domestic business is still the keenest feature of the Cincinnati gateway. Lump coal is scarce, but on the other hand the retail buyers are shying at taking any great amount. They hold fast to the idea of small deliveries until the price comes down to a lower range.

The smokeless situation is hardest to fathom. The demand is good even though $6@$6.50 is the price on mine run and this in the face of the fact that Tidewater prices are $1.50 and more below that. The nub of the situation seems to be that the Western embargoes are holding this back while the seaboard is getting more of this coal than it will absorb. Producers are still selling at the Hoover price, if you wait your turn in filling the order. Jobbers and wholesalers force the price to the limit when they have car numbers to offer.

There has been no change in the retail situation. A large tonnage is on its way down the Ohio in barges, but low water is holding the fleet at Ironton. It will take a couple of hundred thousand tons by water to make any visible effect on the present retail prices being charged here.

HIGH-VOLATILE FIELDS

Kanawha

Although buyers in general were showing an inclination during the closing days of September to stay out of the market in the hope of securing fuel at lower prices, yet the scarcity of coal due to a poor car supply and congestion at terminals was tending to keep up prices. For domestic coal there was a strong demand. Although striking shopmen of the C. & O. are all back at work, the improvement in the transportation situation is not marked owing to the heavier movement of general freight.

Logan and Thacker

Logan mines are still confronted with such poor transportation facilities that the output is not at best more than 40 per cent of potential capacity. Even though buyers were holding aloof there was more than enough demand to absorb the output. Although mines are supposed to ship a large tonnage to the Lakes, little headway was made in getting coal through owing to congestion at piers. Prices were softer on fuel for Eastern delivery and comparatively little tonnage was being consigned there, and especially to Tidewater.

More than half the full time output of the Kenova-Thacker district is being lost through a shortage of cars. The best demand is in the West but difficulty is experienced in getting fuel through owing to embargoes. Lump is not to be had although prospective buyers are willing to pay almost any price for it.

Northeastern Kentucky

In the face of a demand somewhat restricted owing to the effort of buyers to force prices downward, prices are only fairly well established, with gas coal bringing a little more than steam. Inasmuch as operators are experiencing no difficulty in marketing mine run, no effort is being made to produce lump and egg. There has been little change for the better in the transportation situation.

West

SALT LAKE CITY

The coal price probe continues. Many operators and retailers have been examined. Sessions are behind closed doors and there is no indication as to whether prosecutions will be ordered.

Retail business is quiet as a result of the grand jury examinations and warm weather, but mines are still behind on orders. Cars are in crop service. Stocks in the local yards are low. A retailer declared that instead of coal coming down he looked for another raise if the weather sets in cold. This would be necessary to keep the coal from going out of the state.

KANSAS CITY

The coal situation here is anomalous. Dealers expected a strong demand for domestic grades and they are not having it. This is because oil has displaced coal in many plants and because people expect a price drop. Steam coal is in good demand, however, and prices hold firm, but they are on a lower plane than costs of production would justify. One contract for Arkansas slack was closed recently at $1.50 f.o.b. mines and as Arkansas mines make at least 50 per cent slack it will be readily seen that the operators must get a price for their lump to break even, as the cost of production is around $3.75.

Some operators are selling at cost or below. This is hard to understand. Outside competition is not serious as railroads have embargoed most coal from Illinois, and besides, the market here is not strong enough to draw that coal.

DENVER

The report of operators for the week ended Sept. 23 shows a loss of 30.2 per cent production or 63,771 tons, on account of the car shortage on railroads in Colorado and northern New Mexico. Time lost due to mine disability was 2.2 per cent and "no market" 3.7 per cent. During August, 1922, a total of 950,618 tons of coal was produced in Colorado compared with 777,329 tons in August, 1921.

News Items From Field and Trade

ALABAMA

The Parrish Mining & Development Co., of Chicago, is about to open a mine near [illegible].

COLORADO

The Starkville Mine at Louisville, [illegible] operated by the Independent Fuel Co., has been leased for two years to the Standard Coal Co., with offices in Denver, of which [illegible] president, Geo. Engle vice-president and gen. manager and Chas. Dougherty secretary and treasurer. All the officers of the company, Engle, Taylor and Lee Bonnell are experienced in charge of the coal properties, Engle having been in charge of the Independent mine at the time. The Rocket Fuel Co. of Denver is the successful purchaser for the Rocket property.

The Leyden Coal Co. has purchased its mine machine outfitting to be used for more prompt shipments, temporarily using the gathering R. G. for the present if necessary.

The Big Horn Coal & Coke Co. has purchased the electric machines at Crockett [illegible] and two shortwall cutting [illegible] with 36 inches penetration, powered by electric locomotive to the numbers 2 mine [illegible].

Excavations at the Evans mine of the International Fuel Co. will be completed. The mine is being timed preparatory to the construction of a [illegible] railroad spur, the latter for which has been passed.

ILLINOIS

F. H. Mauk, president and general manager of the O'Gara Coal Co. has completed a Chicago office at [illegible] in New York.

C. L. Doring, [illegible] of Chicago, is in the office after a summer in the West.

The Sherman Coal Co. has organized and rebuilt coal & mine [illegible] Sherman County. The contract is [illegible] of R. G. Cooper, president, F. J. Cooper, vice-president, John K. Fisher, secretary-treasurer and C. E. Sherman, mine foreman, all of Sherman, who will be the proprietors of the new company.

The O'Gara Coal Co. of Chicago, is actively completing its local office building at Sherman.

The Vandalia Coal Co., of Vandalia, has been incorporated with capital of $14,000 by Adolph Bondermark, H. Mendelsohn, William Bockman and Edward Pratt.

The coal mine owned by Shane Bros., of Maquon, has been opened and coal has been shipped to the market. The shaft and surface have been completed. There is a 50-ton bunker permitting the company to load.

The Railroad County Coal Co., which has been operating a strip mine at Carrier Mills, has two steam shovels and plans [illegible]. The company, which is owned by F. E. Cooper and Cooper & Mosley, of Marion, E. E. Reynolds of Harrisburg, O. L. Middlebrook of Carbondale and Carter Brown of Benton, Mo., who [illegible] a new corporation under the name of the Cedar Coal Co. at Carrier Mills. The new company has purchased 80 acres of coal near Cedar. They now [illegible] to have it ready for operation by the middle of December.

Williams & Buchanan, of Mt. Carmel, [illegible] the sinking of a new shaft near Denver. Power, hoisting and other machinery will be installed as soon as the pit and [illegible] work will be finished, so many say it is [illegible].

The Lansing Coal Co., Waukegan, has [illegible] & Co., of same city, [illegible] to work [illegible] mine. The machinery is being [illegible] and other improvements being made.

The Coal Valley Mining Co. has leased between 2,000 and 3,000 acres of land along Hickory Creek, just north of Sheridan, and will [illegible] the coal. It is said to be a good thing, as it is [illegible] and other coal companies in the district have been [illegible] with the result that [illegible] will be run [illegible] and up.

The Peabody Coal Co. has purchased the property of the Springfield Marion Coal Co., which has been operating the Centralia mine, and will [illegible] whether or not the city is to proceed further with its plan for the sinking of a municipal coal shaft. The mine now produces about 30,000 tons per annum, most of which is screenings. To pay the [illegible] for coal will add $60,000 [illegible] per year. This would go [illegible] paying the expense of sinking a shaft on the plot, where the city owns [illegible] coal-bearing land.

[illegible] of the Centralia mine, Springfield [illegible] when its three new owners, Edgar H. Buckley, Carl Elsholf and George W. Schwaner took charge. The mine was formerly the property of the Springfield Marion Coal Co., Springfield.

INDIANA

The City Coal Co. at Jasonville, near [illegible], is completing the sinking of a shaft that will begin producing about Nov. 15 through a steel tipple containing a [illegible] shaker screen and an inclined [illegible] screen. Three tracks run under the [illegible] which was designed and constructed by the Krebbiel Co., of Chicago. The mine engineering company is finishing a four-track steel tipple at Winkle, for the Columbia Collieries Co. It will have a capacity of about 350 tons an hour.

The Linton-Mason Coal Co., of Linton, has filed a notice of dissolution with the secretary of state.

The Freeman Fourth Vein Coal Co. has been incorporated at Jasonville with a capital stock of $10,000. The organizers of the company are J. F. Freeman, S. R. Thon and Thos. Lynch.

For the purpose of mining coal the H. D. & F. Coal Producing Co. has been organized at Linton with a capital stock of $10,000. The organizers are Ebert M. Hammach, S. Hicks and Herbert L. Forbes.

The Cressmont Coal Co. recently was organized at Valparaiso with a capital stock of $[illegible] for the purpose of mining coal. The organizers of the company are Alfred R. Putnam, Lucy D. Putnam and Carl F. Mann.

The Insular Coal Co. has been organized at Linton with a capital stock of $150,000 for the purpose of entering the mining business. The organizers of the company are K. L. Ogle, Edward McQuade, T. S. Martin and Samuel Royse, all well known in the coal producing industry.

The [illegible] of one of the Indianapolis superior courts denied recently a petition of the National City Bank, of Indianapolis, asking that a sale of the Rose Hill Coal Co. be set aside. The company was sold in June by Wilhelmi Schrolucke, receiver, and the sale was approved by Solon J. Carter, [illegible] of the same court.

IOWA

J. C. Ward of Kirksville, Mo., is sinking a new coal shaft at Indianola for a syndicate of local business men. The syndicate has leased about 160 acres of land in the vicinity.

Approximately [illegible] tons of coal for state institutions in Iowa has been contracted for by the state board of control. Prices on all of the contracts range from $4.41 per mixed coal to $6.65 for lump.

The Diamond Block Coal Co. of Des Moines, has been incorporated with capital of $[illegible]. J. D. Mc[illegible]land is the president and D. M. [illegible]son is the secretary and treasurer.

KENTUCKY

The Kentucky Gas Coal Co. has incorporated with a capital stock of $25,000, 250 shares of which L. F. Young, T. L. Young and J. F. Caldwell hold three each.

Mine operators and [illegible] officers as well as [illegible] in charge of controlling some of the [illegible] districts of western Kentucky, [illegible], have asked for [illegible] cause as there is [illegible] much territory [illegible] for the number of men employed. It is claimed that union [illegible] from other sections of the country have been coming [illegible] especially in [illegible] efforts to [illegible] strip mines or [illegible] to organize. Men have just been sent to the Hawley-Isaacs Coal Co., plant at Carbondale, likely is also well guarded.

MINNESOTA

Hibbing, Virginia and Eveleth, three iron range towns near Duluth have filled their municipal coal yards for the winter, according to reports. They purchased an aggregate of [illegible] tons of Pocahontas screenings at a cost of about $7.50 f. o. b. Duluth.

F. W. R. Coleman, formerly of the City Fuel Co., Minneapolis, is reported as likely to be named minister to the Balkan states. Mr. Coleman was a captain in the quartermaster's department during the war, and spent two summers in the coal lands of Spitzbergen prior to the war.

A report to the fuel committee named by the mayor of Minneapolis stated that there would be no chance of lower prices on hard coal, that no soft coal reductions were barely possible, that there is no possibility of a normal supply of anthracite coming to this section, and that a bureau of information on coal supply and price should be organized at once. Quick release of coal cars and increased efficiency of transportation are the two hopes expressed by the committee for averting a fuel famine.

Major C. J. Bailey, of the bureau of service of the I. C. C., has been working on the fuel situation in the Twin Cities. He will seek to push the movement of coal from the docks to the interior and will work for obtaining cars and for prompt handling of them when loaded.

MISSOURI

"Gopher hole" mines are opening up all over Missouri, from St. Louis, in the eastern part of the state, to the Kansas and Iowa lines. These various new operations employ from one to as many as fifteen men and get out from 5 to 100 tons per day. Some of these little mines have long been abandoned and others operated at intervals since as far back as 1860. They could not be operated at a profit during the war time fuel administration prices, but are coming back now with no price restriction. This was one of the causes recently for the Missouri Fuel Commission removing mine maximum prices. It caused the opening of new pits, with an increased production that brought coal prices $2 under the fixed maximum. At present they are helping to serve a big population in central Missouri which formerly depended on Illinois coals together with some from Kansas. This much needed Kansas and Illinois coal is now moving north where it is a present necessity. A few of the activities are these: The Central Missouri Coal & Mining Co., of Jefferson City, G. H. Meeker and Herbert L. Hawkins have opened up what is known as the old Hubbard coal mine, located on the Mills farm about seven miles east of Princeton; the Hawk Point Coal & Mining Co. is planning to sink a shaft near Hawk Point; Dr. C. C. Van Hall, of St. Joseph, has leased 130 acres of coal at Harrisonville from Taylor Bros. and will sink a shaft.

The Jones Coal Co., of Rich Hill, has announced that it will begin at once to clean up the shaft at the mine, south of town, and be ready to ship coal soon. About fifty men are employed.

The Lincoln Coal Co. of St. Louis, has been incorporated for $10,000 by M. E. Sullivan, an old-timer in the wholesale trade.

E. Bryson Tucker, connected with the power and mechanical department of the Consolidation Coal Co., of Fairmont, W. Va., has resigned and is now connected with the A. S. Aloe Co., of St. Louis, importers and manufacturers of engineering instruments and supplies.

NEW YORK

Two new coal concerns have recently set up business in Buffalo. Edward J. Delaney, formerly with F. J. McGuinness, in the Builders' Exchange, under the name of the Manufacturers' Fuel Co.; and Henry C. Stone, a former member of the city jobbing coal trade, in the new Lafayette Bldg., under the name of the Continental Oil & Supply Co.

OHIO

Columbus becomes an important center in coal distribution under the ruling of Federal Administrator Spens, who designated Columbus as the headquarters for the Ohio district. Lieutenant Commander H. H. Benson of Columbus has been appointed in charge of the Ohio district. Cincinnati becomes the headquarters for a district comprising all of Kentucky east of the eighty-fifth meridian.

The Speaks-Drais Coal Co., Columbus, has been chartered with a capital of $10,000. Incorporators are Edna L. Speaks, James Loren, Jr., Helene C. Drais, Charles W. Drais and S. S. Speaks.

Because of a revival of rail and river business at Cincinnati there promises to be more tipples for the transfer of barge coal along the Kanawha. A. Ingersoll of the **Cleveland & Philadelphia Coal Co.** has established an office in Cincinnati to direct the transfer of coal brought down the river from the Kanawha mines. On an artificial wave over the canalized river route the company brought down 7,500 tons which was placed aboard railway cars at Cincinnati and moved to points where the rail congestion was not so stringent.

Operators who visited the Cincinnati market recently were: **Quin Morton**, of Charleston, **C. A. Johnson**, of Pineville, Ky., **W. C. Dudley**, of Lexington, Ky., with interests in the Hazard field, **Henry Harmon**, of the Ft. Dearborn Coal Co., of Tazewell, W. Va., and **Abner Lunsford**, of the Banner Fork Coal Co.

The E. J. Lewis Coal Co., Wellsville, has been chartered under Ohio laws with an authorized capital of $150,000 to mine and sell coal as well as mine clay and manufacture clay products. Incorporators are G. L. Brokaw, D. B. Mackintosh, E. J. Lewis, John P. Wilson and S. D. Foster.

The Keystone Coal & Supply Co. has been incorporated at Warren with a capital of $25,000 to deal in coal by L. C. Viets, Edmund E. Gettig, R. H. MacFarland, Myrtle Jeffries and Tom Walsh.

C. E. Bullard, general manager of the Hazard-Blue Grass Coal Corporation, has been a patient at Christ's Hospital, Cincinnati, where he submitted to an operation upon his tonsils.

OKLAHOMA

The Welch Coal Co. is removing dirt on the Eaton farm, five miles west of Welch so it can put on a steam shovel which will arrive soon. A tractor and several scrapers are on the job. The company will employ a big force of men.

W. H. Fogle has opened a new strip pit on the J. A. Mills farm on Big Cabin Creek near Welch. Most of the coal from this mine will go to the Miami lead and zinc mining district.

PENNSYLVANIA

"Not Guilty" was the verdict rendered in the Somerset County court last week by the jury that heard the murder charge against **Robert C. Wallace**, formerly a coal and iron policeman for the **Hillman Coal & Coke Co.**, at Jerome, accused of the killing on Aug. 22 of a striking miner.

Henry E. Waters, president of the Wilmore Basin Coal Co. and the Efficiency Coal Co., is in the Altoona Hospital in a critical condition with a fracture of the skull, as the result of an automobile accident.

Announcement has been made that **C. B. Sturgis**, president of the Pine Hill Coal Co., of 17 Battery Place, N. Y. City, has purchased the Oakhill colliery, of **Whitney & Kemmerer**. Both collieries adjoin each other at Minersville, Pa.

One hundred men recruited in New York were brought in recently by the **Lehigh & Wilkes-Barre Coal Co.** for employment as anthracite mine workers. They are needed, according to a statement issued by the company, to supply a shortage of laborers resulting from the prolonged mine suspension. The newcomers will work as laborers in the mines. Since the end of the five months' suspension, production has suffered from a shortage of labor. The only method remaining to get back to normal production, the company official declared was to hire men from cities outside of the anthracite region.

A charter has been issued to the **Pine Coal Corporation**, Philadelphia, with a capital of $6,000. William McMullin, Bryn Mawr, is treasurer and the incorporators include Mr. McMullen, J. Warner Rhine, Philadelphia, and Edwin S. Dixon, Jr., Ardmore.

The Eureka Coal Co. has filed notice of an increase in capital stock from $10,000 to $30,000. Raymond F. Gelnzer, Allegheny County, is treasurer.

Land owners of Pennsylvania, including many mining companies, will be given 7,000,000 evergreens and hardwood trees for planting by the State Forestry Department this fall and next spring. The mining companies are among the most extensive planters of trees in the state today.

TENNESSEE

The Douglas Coal Mining Co., Nashville, A. Lackel, president, is planning development of the mines at Island, Ky., which will include new hoisting equipment, mine cars and locomotives, electrical machinery and other equipment.

TEXAS

The Empire Fuel Co., recently organized with a capital stock of $5,000,000, and incorporated under the laws of Delaware, will begin operations immediately in the vicinity of Rockdale. The company owns 5,000 acres of lignite lands in Milam, Limestone and Freestone counties, which will be developed. Adam H. Davidson, of Dallas, is general manager of the company, while A. E. Neisanger, formerly efficiency expert of the Dallas Power & Light Co., at Dallas, is vice-president and general superintendent of the plant. M. R. Summers is local manager at Rockdale. The company has taken over the Sparks interests in the Rockdale lignite field, consisting of 1,000 acres of land with five operating shafts and the Santa Fe Lignite Co., of Rockdale, which owns 1,000 acres of land on the Gulf, Colorado & Santa Fe Ry., eight miles east of Rockdale. The company also owns 3,000 acres of undeveloped lignite lands in Limestone County.

WEST VIRGINIA

The Eagle Alma Coal Co. has been organized by Huntington coal men with a view to operating in territory adjacent to Huntington, this company having a capital stock of $750,000. Offices for the time being will be at Huntington. Active in organizing this concern were: E. W. Bowers, W. E. Tomkins, R. C. Taylor, O. Bowers and N. P. Tompkins, all of Huntington.

Organization of the **Stanley Coal Co.** presages the development of additional coal land in Monongalia County. This company, with a capital stock of $100,000, will have its headquarters at Morgantown. Leading figures in this company are: Charles W. Ream, Stanley Ashby, of Crellin, Md.; Samuel A. Kendall, Jr., John W. Kendall, of Meyersdale, Pa.; J. L. Kendall, Sr., Pittsburgh.

Officials of the union in sub-district 4 of district 17, claim that all but six of the companies in that sub-district have entered into an agreement with the union. Five companies not parties to the contract are in Monongalia County and one in Harrison, the one in Harrison being the Hudson Coal Company which declined to sign when there was no assurance given by the union that men who had worked during the strike would be protected. In sub-district 3 there are many companies who have not become parties to the union contract and who are operating their mines on the open-shop plan. The West Virginia Coal & Coke Co. and numerous other companies on the Charleston Division of the B. & O. come within that category and all of such companies are operating on a satisfactory basis.

There were a good many fatal accidents connected with the mining industry of West Virginia during August, twelve meeting death in or around the mines, with thirteen deaths due to falling coal, timber and slate. Mine car accidents were responsible for the death of four and one miner was killed by electrical shock. Three were killed in motor accidents and one in an explosion. Outside the mines one miner was killed in a mine car accident, two from electrical shock and three from miscellaneous causes.

Governor Morgan named the following well-known mining men to represent West Virginia at the annual meeting of the American Mining Congress: **R. M. Lamble**, chief of the West Virginia Department of mines, **Charles E. Krebs**, mining engineer, Charleston, **Everett Brennen**, president West Virginia Coal & Coke Co., Elkins, **J. G. Bradley**, former president of the National Coal Association and president of the Elk River Coal & Lumber Co., Dundon, **S. A. Scott**, general manager New River Company, Macdonald, **A. R. Heisel**, general manager Island Creek Coal Co., Logan; **Walter Thurmond**, president Logan Operators' Association, Logan; **W. N. Cummings**, Red Jacket Consolidated Coal Co., Red Jacket; **J. J. Huddleston**, Excelsior; **W. P. P. Keeper**, secretary Pocahontas Operators' Association, Bluefield; **W. M. Wiley**, general manager Boone County Coal Corporation, Sharples; **George T. Watson**, Consolidation Coal Co., Fairmont; **T. E. Hutchinson**, Hutchinson Coal Co., Fairmont; **Josiah Keeley**, general manager, Cabin Creek Consolidated Coal Co., Kayford.

Some of the operators of northern West Virginia who signed an agreement with the union are beginning to experience again the annoyance of having unlawful strikes to deal with. One of the first was that during the latter part of September at the Morgan mine of the **Virginia & Pittsburgh Coal Co.**, in Marion County, in which 100 miners participated after two cutters had been discharged. These cutters had failed to live up to their agreement. When a ruling was made that their discharge was warranted the miners struck as a protest.

At the Becco mine of the **Buffalo-Eagle Coal Co.** in the Logan field, a demonstration was recently made of the coal loader manufactured by the American Coal Loading Machine Corporation, of Huntington. With operation on a sidewall of coal lightly shot, it had no difficulty in loading continuously at a rate somewhat better than a ton a minute with one man operating the machine and two men trimming the cars, a locomotive spotting and removing the wagons.

BRITISH COLUMBIA

COAL OUTPUT FOR AUGUST, 1922

Vancouver Island District.

Mine.	Net Tons.
Western Fuel Corp., Ltd., Nanaimo.	85,235
Canadian Collieries (D) Ltd.	
Comox	48,518
Extension	21,044
South Wellington	7,417
Granby Cons. M. S. & P. Co.	22,627
Nanoose Wellington Collieries	10,815
Old Wellington	1,182
Total	195,847

Nicola-Princeton District.

Middlesboro Collieries	9,210
Fleming Coal Co.	4,676
Coalmont Collieries	18,759
Princeton Coal & Land Co.	2,205
Total	34,870
Grand total	230,717

That there will be another producing coal mine on Vancouver Island soon would seem assured, as **J. J. Grant**, former manager of the Nanoose-Wellington Collieries, has secured a considerable acreage adjacent to the old "Jingle Pot" holdings, near Nanaimo, and is reported to have started development close to the shipping point already.

ONTARIO

J. A. Ellis, fuel controller for Ontario, has fixed the Toronto price for anthracite at $15.50 per ton, and issued orders that dealers shall not deliver more than one month's supply at a time to a customer and shall not make deliveries to cellars already containing a two weeks' supply of coal. The order does not appear to substitute fuel, nor to the municipalities outside Toronto. The controller states that other municipalities may apply to him to regulate fuel distribution and that he will then see that similar provisions are made available to such localities.

WASHINGTON, D. C.

The United States Civil Service Commission announces an open competitive examination for structural and marine draftsman. Two vacancies at the Naval Operating Base, Pearl Harbor, Hawaii, one at $7.20 per diem and the other at $7.00 per diem, each with an additional allowance of 96c. per diem while employed at the station; a vacancy in the Public Works Department Naval Station, St. Thomas, Virgin Islands, at $6.40 per diem; and vacancies in positions requiring similar qualifications throughout the United States Civil Service. Washington. At these positions the lower salaries will be fixed upon the examination papers to be found to be to the interest of the service to fill any vacancy by reinstatement, transfer or promotion. In the absence of further notice, applications for this examination will be received until the hour of closing business on Dec. 15, 1922. If sufficient eligibles are obtained the receipt of applications may be closed before that time of which due notice will be given.

O. P. Hood, chief mechanical engineer of the United States Bureau of Mines, will return to his office Oct. 16, after having spent three months in Europe on official business. Mr. Hood visited England, Ireland, France, Italy and Germany to study the petroleum, carbonization, coal-dust explosion problems in general, smoke abatement and utilization of lignite and coal.

Support for Mining Machines. Thomas E. Fray, Chicago, Ill., assignor to Goodman Mfg. Co., Chicago, Ill., 1,421,557. July 4, 1922. Filed May 6, 1920; serial No. 379,210.

Trade Literature

Electrically Operated Pumps. General Electric Co., Schenectady, N. Y. Bulletin 44,28. Pp. 19; 8 x 10 in.; illustrated. Shows the feasibility of applying electric motors for driving pumps of all kinds and points out the considerations involved in selecting the best type and construction of motor and control for different installations.—Advertiser.

Hand Book of the Electric Power Club of Cleveland, Ohio. Pp. 284; 4 x 6 in.; illustrated. Contains definitions, symbols, general engineering recommendations and other information needed by users and purchasers of electric power apparatus and control equipment. Single copies will be given free to consulting engineers, electric light and power companies, rated electrical contractors and educators; otherwise the charge is 50c. per copy.

Jeffrey Portable Belt Conveyor. The Jeffrey Mfg. Co., Columbus, Ohio. Bull. 181. Pp. 7, 7 x 10 in., illus. Describes how the conveyor may be made to serve as an extension to storage pile in connection with a Jeffrey portable car unloader.—Advertiser.

The Terry Turbine. The Terry Steam Turbine Co., Hartford, Conn. Pp. 40; 8 x 11 in., illus. Describing the non-condensing and condensing Terry turbines. A short history of the steam turbine precedes the description.—Advertiser.

American Cast Iron Storage Tank. Conveyors Corporation of America, Chicago, Ill. Pp. 8, 4 x 9 in.; illus. Gives the uses to which this tank is particularly adapted are ash storage, containing the discharge from conveyors of various types, and for coal storage around power plants and coal yards.

Synchronous Motors. Allis-Chalmers Mfg. Co., Milwaukee, Wis. Bull. 1124. Pp. 20; 8 x 10 in., illus. Describes the use of these motors for driving mine fans and motor generator sets.—Advertiser.

Eliminating Waste in Blasting, by N. S. Greenwalder. Hercules Powder Co., Wilmington, Del. Pp. 48; 6 x 9 in.; illus. Among the subjects touched on in this book are: Planning the work, drilling, choice of explosives, use of larger sizes, distribution of explosives, advantages of No. 8 blasting caps, use of stemming.—Advertiser.

Protection up to Date. The Cutter Co., Philadelphia, Pa. Pp. 15; 4 x 7 in.; illus. Describes the uses to which the I-T-E circuit breaker or U-Ra-Lite may be put, with tables for voltages and prices.

Engineering Bulletin on Pneumatic Collecting and Conveying. B. F. Sturtevant & Co., Hyde Park, Boston, Mass. Pp. 72; illustrated, charts and tables.

Willson Safety Goggles and Dustite Respirators. Willson Goggles, Inc., Reading, Pa. Pp. 12, 5 x 8 in., illustrated. Describes goggles for different kinds of work, and the dry and wet filter types of dustite respirator, with and without relief valve.

Association Activities

Fayette-Greene Coal Producers' Association

Permanent organization of the association was effected recently and plans for the work of the organization were discussed in detail. R. W. Gardiner, commissioner of the Pittsburgh Coal Producers' Association, addressed the new association at its Uniontown meeting on the various phases of association work and the benefits to be derived therefrom. He spoke briefly of the valuable work being accomplished by the Pittsburgh association and touched upon new legislation which has just been enacted affecting the coal industry.

There was a large attendance at the meeting who indorsed the tentative association which was formed the latter part of July and which was made permanent. Headquarters will be opened in Uniontown shortly and the organization will begin effective work. George Whyel is president, W. W. Parshall vice-president, and E. D. Brown secretary and treasurer. The detail work of the association will be in charge of an executive secretary.

National Coal Association

The Cost Accounting Committee of the Association, appointed as of June 1, 1922, is composed of the following: Brewster, T. T. (chairman), president, Mt. Olive & Staunton Coal Co., St. Louis, Mo. Barker, G. H., vice-president, Maynard Coal Co., Hayden-Clinton Bldg., Columbus. Barnum, Walter, treasurer, Pacific Coast Co., 50 Church St., New York City. Honnold, F. C., secretary, Coal Operators' Associations, 2017 Elsher Bldg., Chicago. Huff, W. H., president, Victor-American Fuel Co., Denver, Col. Randall, Robert, general manager, Consolidated Coal Co. of Saginaw, Saginaw, Mich. Sampson, W. J., president, Witch Hazel Coal Co., Youngstown, Ohio. Allport, J. H., Barnesboro, Pa. Bowles, A. K., general auditor, Consolidation Coal Co., 67 Wall St., New York City. Drennen, E., president, W. Va. Coal & Coke Co., Elkins, W. Va. Francis, J. D., vice-president, Island Creek Coal Co., Huntington, W. Va. Hornberger, J. B. L., vice-president and comptroller, Pittsburgh Coal Co., Pittsburgh. Johnson, W. L. A., secretary, Southwestern Interstate Coal Operators' Association, Kansas City, Mo. Lewis, T. L., secretary, New River Coal Operators' Association, Charleston, W. Va. McKinney, W. D., secretary, Southern Ohio Coal Exchange, Columbus. Norris, R. V., 524 Second Natl. Bank Bldg., Wilkes-Barre, Pa. Ramsay, Erskine, first vice-president, Pratt Consolidated Coal Co., Birmingham, Ala. Reed, W. B., secretary, National Coal Association, Washington, D. C. Watkins, C. Law, president, Watkins Coal Co., Cresson, Pa.

Coming Meetings

Kentucky Mining Institute will hold its annual meeting Nov. 3 and 4 at Seeback Hotel, Louisville, Ky. Secretary, Elizabeth C. Rogers, Lexington, Ky.

The National Industrial Traffic League will hold its annual meeting Nov. 15 and 16 at the Hotel Commodore, New York City. Secretary, J. H. Beek, Chicago, Ill.

Coal Mining Institute of America will meet Dec. 13, 14 and 15 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., 911 Chamber of Commerce Bldg., Pittsburgh, Pa.

National Exposition of Power and Mechanical Engineering will be held at the Grand Central Palace, New York City, Dec. 7-13. Manager, Charles F. Roth, Grand Central Palace, New York City.

American Gas Association will hold its annual meeting Oct. 23-28 at Atlantic City, N. J. Secretary-Manager Oscar H. Fogg, 130 East 15th Street, New York City.

Canadian Institute of Mining and Metallurgy, annual Western meeting Nov. 15-17, at Vancouver, B. C. Secretary-Treasurer, G. C. Mackenzie, Montreal, Quebec, Can.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, Editor

Volume 22 NEW YORK, THURSDAY, OCTOBER 19, 1922 Number 16

More—or Less—Unionism

INTERESTINGLY written is James W. Cain's recital of facts in "The Battleground of Coal," in the current issue *The Atlantic Monthly*. But it is not with his facts but with his theories and his cures that the public is justified in taking issue. He shows that before the strike the union mines were idle for lack of orders and the non-union mines were working, their activity being due to lower wages. Then he adds:

> From the foregoing it would seem that the solution of the problem lies in putting the whole country on a non-union basis. This is just what the operators are trying to prove. Not only the non-union operators but the union operators as well distribute this propaganda; newspapers are flooded with it. Yet it is clear that the argument of the operators is valid only in a superficial sense, even though present conditions lend it considerable plausibility. For obviously the prosperity of the non-union fields prevails not through any superiority of non-unionism *per se* but from the artificial advantage they have on account of their lower wage expense.

Mr. Cain is right; the enslavement of part of the industry to the United Mine Workers of America and the freedom of the other part from it is the cause of the wage differential and of the inequality of operation in the two districts which existed before the strike. But he has taken on himself to oppose the cure that many operators suggest, and the one which he himself admits is the more obvious outcome of the facts he has presented. Eliminating the cure of national non-unionism he says:

> There is one plan left—short of a big government corporation to run all coal mines—which promises some sort of solution. This is to put the whole country on a union basis and give all operators an equal chance at the market and all mines an equal chance at regular work.

Miners are now reported as making, where they get sufficient railroad and mine cars and are willing to work, as much as $500 and $600 a month. Surely they would not be willing to pay as much as $20 or $25 a day to those who would work for them.

Are they not demanding by the power of their union that other men work in mills and factories, on the high roads and on the railroads and at the desk for less money than they are willing to accept for themselves? We do not put any figure as being a fair wage for any man. We do not condemn labor profiteering. Nor does the law condemn it. Doug Fairbanks, Feodor Chaliapin and Babe Ruth may make their millions or hundreds of thousands or tens of thousands yearly so long as they do it without a combination in restraint of trade. We do condemn them, however, if they obtain high wages by deliberate conspiracy, by murder and other violence, by arson and violation of pledges, by the enactment of laws which while purporting to be for the public good are framed solely to sustain their monopoly and to give them an unfair advantage.

But mark this. The complete unionization of the mine worker would mean the complete unionization of his employer, legal or illegal. The union in fact demands a co-operative bargain between all the employees and all the employers. With all operators paying a scale fixed by a single conference, the employer could laugh at high wages. He would have no incentive to fight to keep wages down, for strikes would be extremely expensive to him as a capitalist. The higher the wages, the more men would flock to his mines. He would have no difficulty in filling the working places no matter how irregularly he worked.

Consequently complete unionization of the mine worker would do great injury to the public unless the government stepped in to prevent it. Mr. Cain does not want that, nor do the operators, but it would be the inevitable result of 100 per cent unionism.

Mr. Cain goes on to say that "it would be a step back to the Dark Ages to put the whole country on a non-union basis. The miner would be reduced almost to peonage." In this he is absolutely wrong. Just before the strike came to an end the non-union United States Steel Corporation, anxious to get men, had to raise wages. The Anaconda Copper Mining Co., at Butte, Mont., now a corporation employing non-union men, is paying $4.75 a day to miners and would, if it could afford it, raise the wage still higher to get men to operate its plants. The Cœur d'Alenes are paying $5 a day.

The wage of non-union men is usually lower than the pay of union men, but that is because the profits of any trust are higher than those of a competitive industry. The profits of a trust, whether a commodity or a labor trust, are sure to be excessive unless the prices of the commodities or the wages of the laborer are set so high as to discourage industry.

It is an ill time to talk of giving Mr. Lewis and his men a firmer hold on the throat of the public when they are demanding a six-hour day and a five-day week in order to furnish men with excessive opportunity in the coal industry when they are needed more elsewhere.

A Maligned Industry's Opportunity

THE announcement of the personnel of the U. S. Coal Commission has been met with mingled cheers and jeers by the coal men. Few appear to evidence hope or anticipation that the commission will or can do much for the soft-coal industry. The public has been led to hope that this agency will lower the price of coal and stop strikes. It, of course, can do neither. The coal men are today in about as pessimistic a mood as they ever have been. Battered between the forces at Indianapolis and Washington they entertain little hope of finding their way out of trouble.

Many there are who hold with Mr. Maurer, in his Cleveland address last week, that since the United Mine Workers will not arbitrate and will not take a reduction

Progress at the Mining Congress

A LOOSE, ungainly organization, the American Mining Congress is making progress in taking on some of the functions of older organizations. Not a few of those who attended the Cleveland meeting last week commented on the excellence of the programs and discussions on mine taxation and standardization of mine equipment and mining methods and did not hesitate to compare them with similar efforts conducted under the auspices of the American Institute of Mining and Metallurgical Engineers. In fact, the so-called standardization conferences really are engineering discussions where the everyday problems of mining are taken up by young men not afraid to be trite at times if they can talk about the things that concern them in the routine of their business.

The mine-taxation conference this year called together many of the country's authorities and the interest in the discussion proves that this subject is gaining in popularity every year. Such open discussion of the coal questions of the day as characterized the Wednesday morning session, when J. G. Bradley, of West Virginia, and C. E. Maurer, of Ohio, had the floor, has never been heard at a meeting of coal men—at least a public meeting.

As the advertising pages of a magazine are to the reading pages so the exhibit of mining machinery and equipment supplemented the meetings and discussions. To some in attendance it appeared that the management of the desire, and perhaps necessity, to return a profit subordinated all to the "show," and relegating important meetings to low-ceilinged, poorly ventilated rooms gave value to this belief. The exhibit, of course, added interest and value to the congress, but care should be taken not to add to the belief that these conventions are merely gatherings of salesmen.

A queer conglomeration of coal mining institute, coal operators' gathering, meeting of economists, Institute of Mining Engineers and county fair, at which no particular attention was paid to the advance slogan, "Greater Prosperity Through Lower Production Costs," the silver anniversary of the American Mining Congress was a success. To this success the coal men of Ohio in particular contributed no small share.

Efficiency vs. Reduced Wages

IN 1921, when coal was in slack demand and prices falling, the operator of a coal mine was offered a railroad-fuel contract for a tonnage representing more than half full-time operation, but at a figure what would not return cost. Business was difficult to get and his men needed the work. He called them together, told them the situation, said that he was willing to take the contract if he could be assured of sufficient margin to cover interest, depreciation and depletion—that is, fixed charges, but no profit. He told the men he was not willing to ask them to take a reduction in wages, but he was asking them to increase their efficiency.

After some debate the proposal was made and accepted by the men that 10 per cent be deducted from each pay envelope and held in escrow, as it were, this amount representing approximately the difference between cost and price. It was put up to the men to increase their efficiency, thereby lowering costs, and it was agreed that if they did their part the 10 per cent held out would be returned.

Now, of course, to increase efficiency here meant the exercise of hearty co-operation between men and management, particularly with the daymen. It meant studious avoidance of preventable mine failures, derailments and mechanical breakdowns. It meant working with a will, getting cars to the diggers, shooting loads to the shaft bottom—for this was a shaft mine—it meant steady application to the daily task, whether track laying, dumping coal or any of the many jobs about the coal mine. On the part of management it meant keen appreciation of the value of the time of the tonnage man, giving him a proper place in which to work and such prompt service as his ability to load required.

By the end of the first pay the preliminary cost sheets indicated that it had been done—that costs had been lowered in sufficient amount without cutting wages. Every pay thereafter the men received two envelopes, one the full rate less 10 per cent and the other deducted 10 per cent in accordance with the agreement with the men.

It is needless to say that this was a non-union mine. It is also needless to say that this mine was an exception among the non-union mines in 1921. There was nothing particularly humanitarian about the course pursued by the management of this mine, for there were cogent reasons for the method followed, reasons found in union mines in close proximity on every side. The fact remains, however, that in the absence of a union it was possible to get close enough to the men to substitute efficiency for reduced wages.

WITH THE COMING OF A COAL PEACE there remains nothing to worry about except the delivery of coal and the arrival of the bill.—*Brooklyn Eagle.*

NO SYSTEM OF GOVERNMENT will work in a land where everybody tries to work the government.—*Illinois State Register.*

CHARLES P. NEILL

United States Coal Commission

Appointed Oct. 10 by President Harding. Under Act of Congress Approved Sept. 22, 1922

United States Coal Commission Named

President Harding announced Oct. 10 his selections for the federal commission which will make an exhaustive study of the problems of the coal industry. The White House announcement carried a brief biographical statement. The text of the White House announcement in full is contained in the following:

John Hays Hammond, native son of California, where he was born in 1855, was one of the remarkable group of Californians who led in making the mining of the precious metals the highly specialized and scientific industry it is now. Educated at Yale, Sheffield Institute and Freiberg, Germany, he became one of the foremost engineers and authorities, examining and handling properties in all parts of the world. He was associated with the Barnato Brothers and with Cecil Rhodes in developing the South African gold fields, and was one of the supporters of the great Rhodes political and financial projects. Following the famous Jameson raid, he was arrested by the Dutch authorities and sentenced to death; afterward commuted to fifteen years' imprisonment and ultimately released on the payment of $125,000 fine. Since returning to the United States he has continued his professional work in connection with important financial interests and he has lectured and written extensively. He was special ambassador and representative of the United States at the coronation of King George V; head of Panama Pacific Exposition Commission to Europe; president National League of Republican Clubs; associated with many scientific, literary and technical societies. His present home is in Washington.

Thomas Riley Marshall, vice-president during the eight years of the Wilson administration, is a native of Indiana. He is a graduate of Wabash College; practiced law at Columbia City, Ind., and was Governor of Indiana, 1909 to 1913.

Judge Alschuler a Noted Labor Arbitrator

Judge Samuel Alschuler was born in Chicago and has practiced law in Aurora and Chicago. He has been active in Democratic politics throughout many years, having served in the Illinois Legislature, and has been his party's candidate for Congress and, in 1900, for Governor. In 1915 he was appointed by President Wilson to the circuit bench of the Seventh U. S. Circuit, on which he still is serving. Judge Alschuler in 1918 was named by the Secretary of Labor as arbitrator of the labor disputes between the Chicago packers and their employees, and his handling of the business has been recognized as one of the notable labor arbitrations in this country.

Clark Howell, editor of the *Atlanta Constitution*, is a native of South Carolina, but has lived most of his life in Georgia, and was educated at the University of Georgia. He joined the Constitution staff and became managing editor when Henry W. Grady died; later he succeeded his father, the late Evan P. Howell, as editor in chief. He served in the Georgia Legislature and for many years as Democratic National Committeeman for Georgia.

George Otis Smith, Director of the U. S. Geological Survey, a native of Maine, was educated at Colby College and at Johns Hopkins. His interest in coal began in 1895 and 1896, when as an assistant geologist of the U. S. Geological Survey he was working in the vicinity of the coal fields of western Washington. Later in the field seasons of 1898, 1899 and 1901 his geologic work in central Washington included the mapping of the Roslyn coal field, the Roslyn seam being then the largest producer on the Pacific coast.

In the first comprehensive treatment of the United States coal fields by the U. S. Geological Survey in 1901 Dr. Smith contributed the chapter on the Pacific Coast coal fields. As Director of the U. S. Geological Survey since 1907 he has taken special interest in the development of the statistical service on coal, first with E. W. Parker, next with C. E. Lesher, and since 1919 with F. G. Tryon, latter having thus practically seen up all that is known of coal statistics.

In 1917 Director Smith was a member of the Committee on Coal Production of which the late Francis Peabody was chairman. In 1920-21 the "Superpower Survey," a coal-saving investigation under the auspices of the Geological Survey, engaged much of Director Smith's time.

Dr. Edward T. Devine is a native of Iowa, educated at Cornell College (Iowa), University of Pennsylvania, University of Halle, Germany. He has been a teacher, writer and lecturer on social and economic questions; general secretary of the Charity Organization Society of New York; editor of the *Survey* for a number of years and more recently a contributing editor; served with the American Red Cross in France during the war; author of many books and articles, especially on philanthropy and charity. Residence, New York City.

Charles P. Neill is a native of Illinois; educated at Notre Dame University of Texas and Johns Hopkins; instructor in political economy at Notre Dame and later at the Catholic University, Washington. In 1905 he was made commissioner of labor by President Roosevelt, later commissioner of labor statistics, Department of Labor. He was a member of the Board of Adjustment under the Erdman Act for the adjustment of labor disputes between railroads and their employees, and has had a long career of unfailing success in the settlement of the most difficult questions of this kind through mediatory processes. He has since 1915 been manager of the Bureau of Information of the Southeastern Railways, dealing with labor problems and conditions.

Organization Meeting to Be Held Oct. 18

The commission will meet for organization purposes on Oct. 18. While Mr. Marshall and Dr. Smith each has been mentioned for the chairmanship of the commission, it is believed that Mr. Hammond will be named for the post.

Practically all comment on the personnel of the commission is favorable. It generally is regarded as a good blend of conservative and liberal opinion. Perhaps never before has any investigation of coal by a federal agency started with so little prejudice. It has the great advantage of having a personnel which is not in any way interested in making political capital out of their fact-finding activities. In this way the commission differs greatly from the efforts of several congressional investigating committees. It is believed that both operators and mine workers hardly could ask for a more sympathetic group before whom to lay their facts.

Particular satisfaction is manifested in all quarters in Washington at the appointment of Mr. Hammond. His name has been linked so prominently and so intimately with the mining industry that it is regarded as particularly fitting that he should participate in what is expected to be one of the most important steps taken in connection with coal in recent years. While a man of wealth, Mr. Hammond has a reputation of being sincerely concerned with the public welfare.

It is believed that Mr. Neill has the confidence of both operators and mine workers. It is conceded that he knows more than anyone else, outside of the coal business, as to the conduct of collective bargaining in that industry. His long experience with employer-employee relationships leaves him with no delusions as to the inside situation in each camp.

Mr. Marshall is nationally known as a friendly type of philosopher with a real sense of humor. He has a general desire to ascertain honestly the other man's point of view and to do constructive things. At the same time he has none of the objectionable characteristics of the professional uplifter or one with trust-busting proclivities.

Judge Alschuler has given many indications of judicial balance and a sense of fair play. He is best known to the coal industry for his part in refusing to sustain Judge Anderson's check-off injunction.

Mr. Howell is a Southern editor but not of the fire-eating variety. He is a conservative and accustomed to pass dispassionately on questions of great moment.

Dr. Devine is held in universal regard and has that characteristic of good-will and friendliness which seems to run through each of the members of the commission.

Mining Brown Coal in Germany, Briquetting It and Extracting Its Byproducts

By Hubert Hermanns
Berlin-Pankow, Germany

Growing Importance of Brown Coal—Mining and Stripping Methods—Large Percentage of Moisture—Drying with Exhaust Steam—Briquetting and Baking Coal for Byproducts—Producer Method of Utilization

IN NO country has the production and utilization of brown coal[1], or rather brown lignite, had more development than in Germany. This substance has of late years become of greater importance to the Republic by reason of the decreased output of coal due to the decreased efficiency of the miners and to the loss of the important coal fields in Upper Silesia and the Saar valley. Moreover, large quantities of coal have to be delivered regularly to France, Belgium and Italy.

Table I shows the development of the production of coal, brown coal and brown-coal briquets in Germany between 1913 and 1920 and 1921.

TABLE I—PRODUCTION IN GERMANY OF COAL, LIGNITE AND LIGNITE BRIQUETS

Year	Coal (Steinkohl), Metric Tons[1]	Lignite (Rohbraunkohl), Metric Tons[1]	Lignite Briquets (Braunkohlenbricketts), Metric Tons[1]
1913	190,109,440	87,233,084	21,976,744
1920[2]	131,340,797	111,880,413	24,273,480
1921[2]	136,210,088	123,011,250	28,243,017

[1]A metric ton equals 2,204 lb., or 1,102 short tons.
[2]Not including Saar District and Pfalz. Though from 1913 to 1921 the coal production declined from 190,000,000 metric tons to 136,000,000, the brown-coal production increased from 87,000,000 to 123,000,000 and the brown-coal briquet production from 21,000,000 to 28,000,000.

The character of the brown-coal deposits in Germany varies greatly. Faults, folds, thrust faults, ruptures and interstratified layers of sand and shale often make the mining of the deposit quite difficult. The thickness of the bed varies from a few inches to 300 ft. The method of mining, whether by strip pit or by underground mining, depends on the depth of the deposit over the coal, the overburden consisting chiefly of sand and clay. When underground mining is adopted the coal is reached by a shaft and less often by a drift. Before the war a miner working underground in coal mines could be relied upon to mine 260 short tons per year, whereas the yearly production of brown coal per miner was between 350 and 400 short tons.

HOW THE GERMAN MINER AVOIDS USE OF BACKBREAKING SHOVEL

Another scene in a brown-coal strip pit. Note that the miners are forming a chute in the coal that will feed into the car without shovelling and have erected a chute with a gate so that the coal will be stored and the car will move away without delay. Thus the men will be able to work without cessation while cars are being placed.

By the use of the land dredger the production in strip pits has been raised to more than 1,500 tons per miner. Unfortunately the heat value of this lignite is only about one-third that of coal. However, even making due allowance for the lower calorific value of lignite, each man in a lignite operation will produce many more heat units than a man in a German coal mine. Whereas a coal miner would produce 2,000,000,000 calories per year, the yearly production for a miner working in brown coal is now 3,200,000,000 calories.

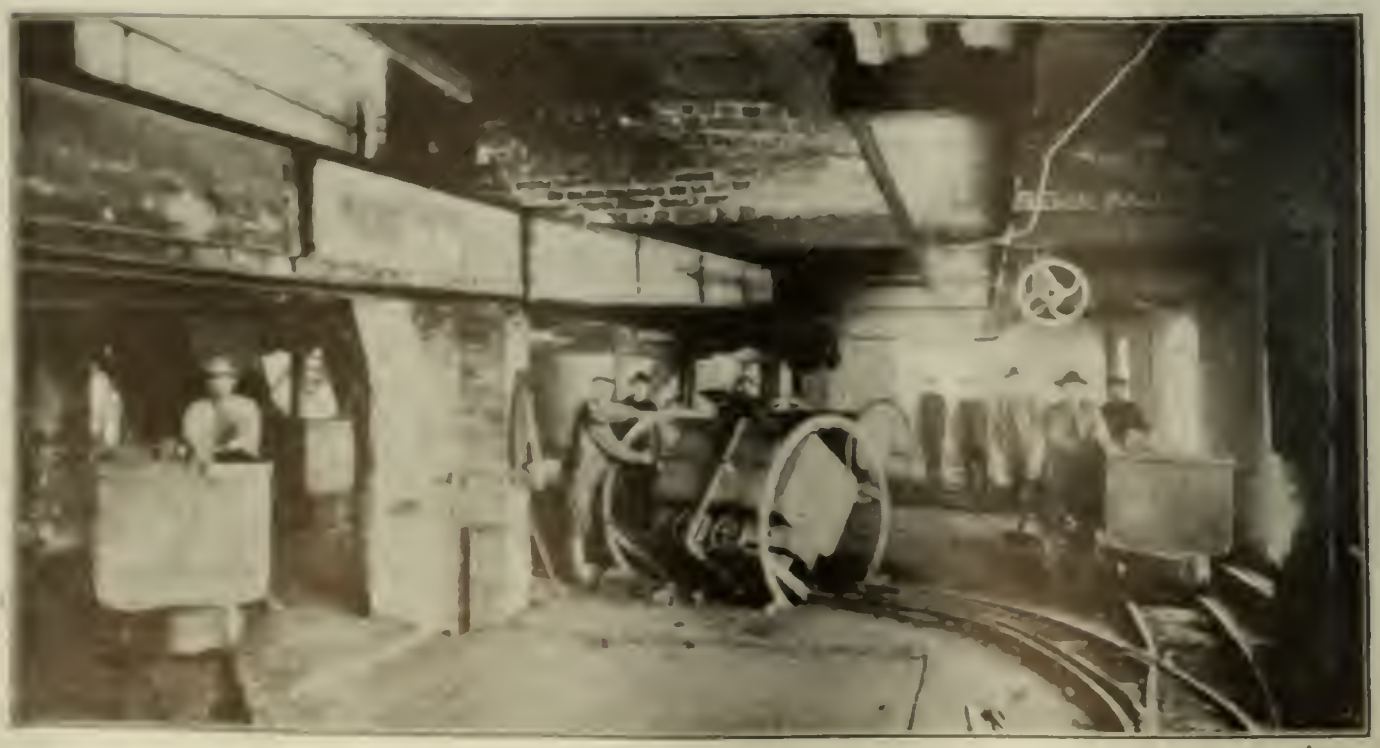
When brown coal is mined by underground methods an entry is driven through the deposit to the further property line with side entries on either side at regular distances and cross roadways between these; thus the coal is divided up into pillars measuring 4 meters (13 ft.) square. The coal obtained from these pillars is transported through the side entries to the main entry and up through the shaft.

The roof of the area thus excavated is allowed to

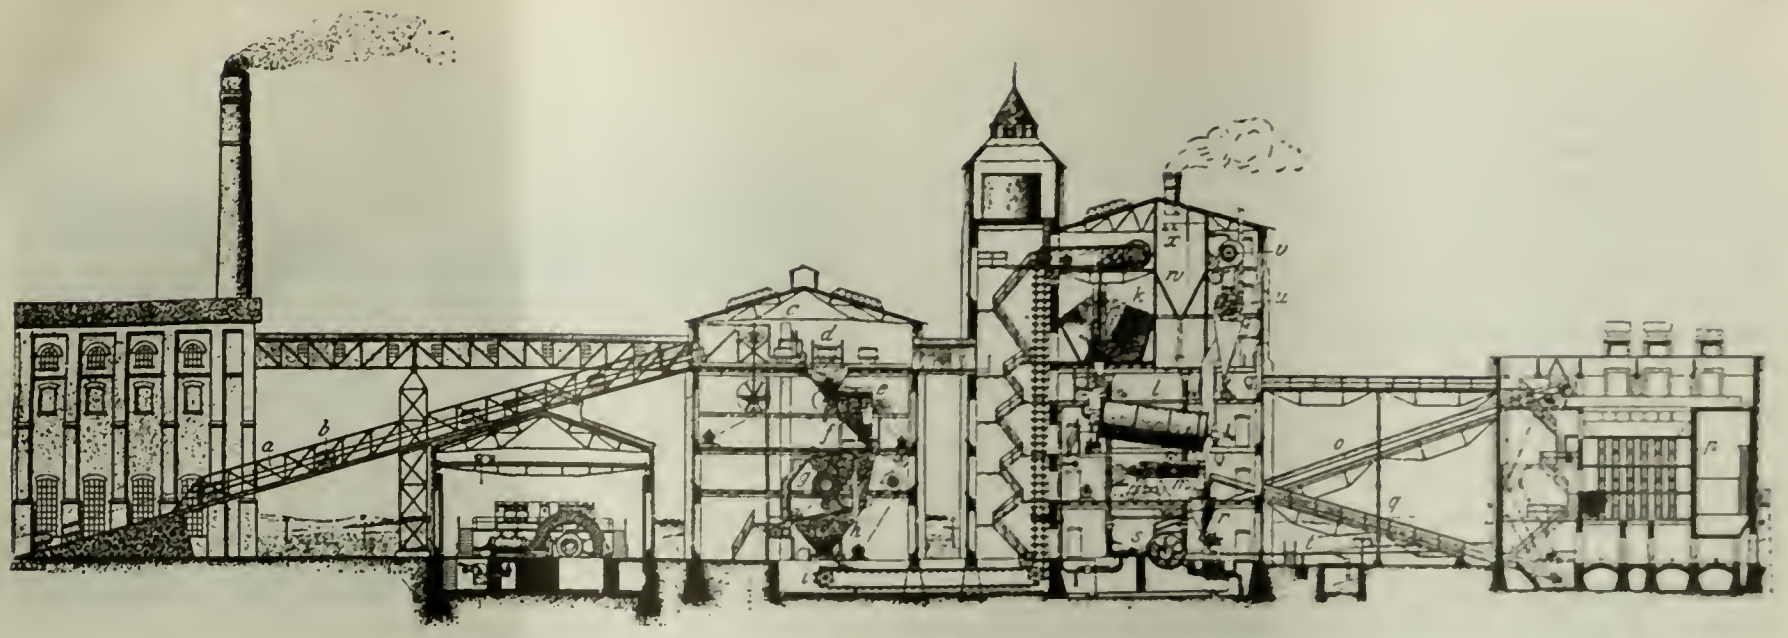
Note—Headpiece shows a miner working a cut at the base of a bisected funnel in the face of the open coal in a strip pit in Germany. The coal in this funnel runs, usually by gravity, into a car which a recess has been made in the floor to permit of its being spotted at the mouth of the funnel. Note the hoe-like pick the workman is using. Picks such as these have extensive use in the Continental coal fields of Europe. The shovel and car also are of what to us must appear unusually small proportions. The car is built like those used in our metal mines and, to our way of thinking, is needlessly high and better suited to a heavier material than coal. It is intended for a rotary dump.

A great entrance to one single drift mouths, which, though enormous, like those in the preceding illustration, rarely have anything more elaborate than a simple segmental arch. This "Gedenkhalle" is at the mouth of the Victoria mine. The word "Glückauf," meaning "Good luck," over the keystone of the arch and between the pediments will perhaps be hard to decipher.

collapse, forming at the surface a broken or sunken field. Production is started at the far end of the field and proceeds backward toward the shaft. Much lignite has to be left, however, and the losses of mineral in these mines usually exceed 40 per cent, whereas by daylight mining the losses are only about 5 per cent, seldom reaching 10 per cent. The losses by underground mining are such that if the overburden is two, or even three, times as thick as the coal deposit it is nevertheless profitable to remove it rather than work the mineral by underground mining methods. The difficulty in daylight mining is in disposing of the impurities mixed with the lignite. These are thrown into the areas already mined.



When the coal is mined by hand in these strip pits it is directed into cars by chutes laid close to the coal, or holes are dug in the face of the coal in the shape of a semi-funnel, and by these the coal is chuted into the car. (See headpiece.) This method is known as *rollochbetrieb*. The narrow end of the "rollloch" is closed by boards and is placed so high above the level of the top of the car to be loaded that the latter can be run under it and filled by gravity, the loose coal in the funnel being released as desired. Usually the sides of the rollloch are made so steep that the loosened lignite will run down them without any assistance from the miner.



As Table I shows, most of the coal is burned without being briquetted. The use of this coal in its natural condition is limited because it contains from 25 to 50 per cent of moisture. The freight rates, figured on the basis of its heat value, are too high to encourage the use of such fuel. The heat value sometimes falls as low as 2,000 calories, or 3,600 B.t.u.

The difficulties encountered in burning this wet coal have been overcome in course of time by the construction of special furnaces in which the coal is dried before reaching the grate, but the principal way in which the economic value of brown coal can be increased is by its use in the manufacture of briquets. The cars are mostly conveyed by continuous chain haulage from the mine to the briquet plant. Three separate operations have to be performed. The lignite must be prepared, dried and briquetted.

First the coal is discharged from the car by a rotary dump. It falls into a funnel-shaped bunker, from which it goes to the crushers. The broken coal from these drops on an inclined shaking screen 13 to 20 ft. long and about 4 ft. wide. This allows particles less than ½ in. in diameter to fall through, the larger pieces going to rollers or a centrifugal mill. The finer coal is screened again, and the lumps coming from the screen are guided to a belt conveyor by which the coal is transported to the boiler house. The wet coal is dried either in tubular driers or on shelves heated by exhaust steam, this process usually being continued until the water content falls to 15 per cent. For tubular driers the pressure of the exhaust steam should be from 2 to 3

Reviving Dump

PLANT FOR CRUSHING, SIZING, RECRUSHING, RESIZING, DRYING, COOLING AND BRIQUETTING BROWN COAL

(a) Endless chain, (b) coal car, (c) drive for endless chain, (d) revolving dump, (e) crusher, (f) shaking screen, (g) centrifugal crusher, (h) shaking screen, (i) bucket conveyor, (k) coal pocket, (l) tubular drier, (m) screening trommel, (n) fine crusher, (o) belt conveyor leading to cooler, (p) cooling apparatus with shutters, (q) belt conveyor from cooler, (r) funnel-shaped hopper over press, (s) briquetting machine, (t) trough conveyor for briquets, (u) centrifugal separating head serving to eliminate dust from drier, (v) exhauster to draw dusty air from u, (w) discharge louver, (x) spray to settle remaining dust.

atmospheres absolute. When shelves are used the pressure should range between 1.5 and 2 atmospheres.

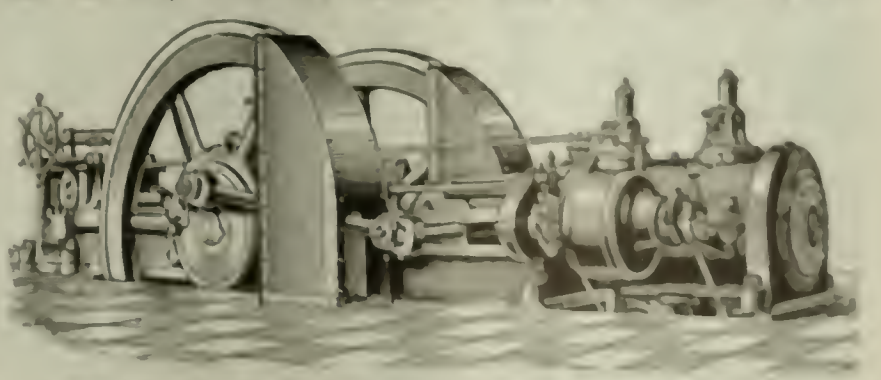
The tubular driers consist of a sheet-iron shell 8 ft. 2½ in. to 9 ft. 10 in. in diameter and 23 ft. to 26 ft. long and two strong ends in which are inserted tubes of 3¾ in. diameter such as are used in tubular boilers. The coal slides through the tubes, which are surrounded by exhaust steam. The center line of the drier is at an angle of 6 deg. with the horizontal.

The shelf drier (*tellertrockner*) consists of twenty-five to thirty-six circular shelves of 16 ft. 4¾ in. diameter placed vertically above each other at regular distances. These shelves are each made of two circular iron sheets riveted to a frame, the space between them forming a chamber for the exhaust steam. By means of rotary shovels the lignite is constantly turned over and pushed alternately toward openings in the middle and on the outside which connect the separate shelves.

The dry coal goes to a trommel, or revolving screen, and is separated into fine coal and coal dust. It is then cooled in a *jalousiekuehler*. You have seen the small shutters on a Venetian blind; in Germany the latter is known as a *jalousie* (or jealousy) because it allows one to look out without being seen. In the cooler just named the coal falls on shutters similar to those in a Venetian blind, and between them cool air circulates. The lignite is cooled because it can be better pressed in briquets when its temperature has been lowered. Conveyors bring the dried and cold lignite to a bunker placed over the briquet presses.

Brown-coal briquets were manufactured as early as 1858, the coal briquetted being from the Von der Heydt mine. Many technical difficulties were encountered, however. In particular the pulverizing and drying apparatus both proved inefficient. All equipment and methods have been so greatly improved since that date that no more technical questions remain for solution.

Today plunger presses driven by steam are used almost exclusively for briquetting. Electrically driven presses are seldom seen; not because the drive is unsuited to that purpose but because exhaust steam is needed for the drying apparatus. The steam engine and press are combined in one heavy frame with a heavy crankshaft, common to both, in between. On this flywheels are mounted.



The stroke varies from 6¼ in. to almost 11 in., depending on the condition of the coal and the desired density of the briquet. A rod transfers the crank movement to a heavy slide to the other end of which the plunger of the press is attached. The principal part of the press is the head in which is placed the mold consisting of a passageway 3 ft. 3 in. long open at both ends. The sides of the mold are of interchangeable steel plates, so set that the free opening is of the desired dimensions for the briquet being manufactured. The plates are so formed that the opening on the press side is a few millimeters wider than the rest of the passageway.

Briquetting Pressure Many Tons Per Square Inch

The difference in width depends on the nature of the coal and the desired firmness of the briquet. The opening can be regulated while the press is in operation. The plunger, fitting closely in the widest end of the channel, pushes a quantity of dry coal into the mold, and forms a briquet with every forward movement.

On the return stroke the space left by the retreating plunger is filled again with another measured quantity of coal, which is formed into a briquet at the next stroke. Each briquet is pushed forward in the mold by the one that succeeds it. On passing the narrowed part, the briquet is again subjected to pressure, causing much friction and consequently back pressure on the plunger.

Leaving the passageway the briquets land in a trough, through which they are pushed in a continuous string by the action of the plunger. The trough can be adjusted horizontally and vertically. The briquets usually fall directly into the railroad cars by which they are

STEAM PRESS FOR MANUFACTURE OF BRIQUETS

So much exhaust steam is needed for the drying of the moisture in the brown coal that steam engines are preferred to electric drives. The press and the engine are on a common foundation plate and a single crankshaft serves for both ends of the unit. The briquetting pressures run from 8 to 14 short tons per square inch and the revolutions per minute from 60 to 150.

taken to market. An illustration shows the pressroom of a briquet plant with eight presses. The construction of the press and the trough can be clearly seen.

Not only the length of the stroke but the speed of the press depends greatly on the condition of the coal; the speed is from 80 to 125 r.p.m. The pressure required for the forming of a briquet is from 1,200 to 2,000 atmospheres, 17,640 to 29,400 lb. per square inch. The press must be built so that the flywheels are capable of exerting such a pressure.

The dry coal is held together without any added binder, partly as the result of the high pressure exerted on it and partly through the heat generated in the process which softens the coal and the substances it contains, such as paraffin and resins.

Naturally the capacity of a press depends on the number of revolutions per minute and the weight of the briquets. In about twenty-four hours one machine will make from 60 to 100 long tons. The shape of the briquet varies greatly for industrial purposes, preference being shown for small cube or net-shaped briquets.

Some Brown Coal Cokes Quite Readily

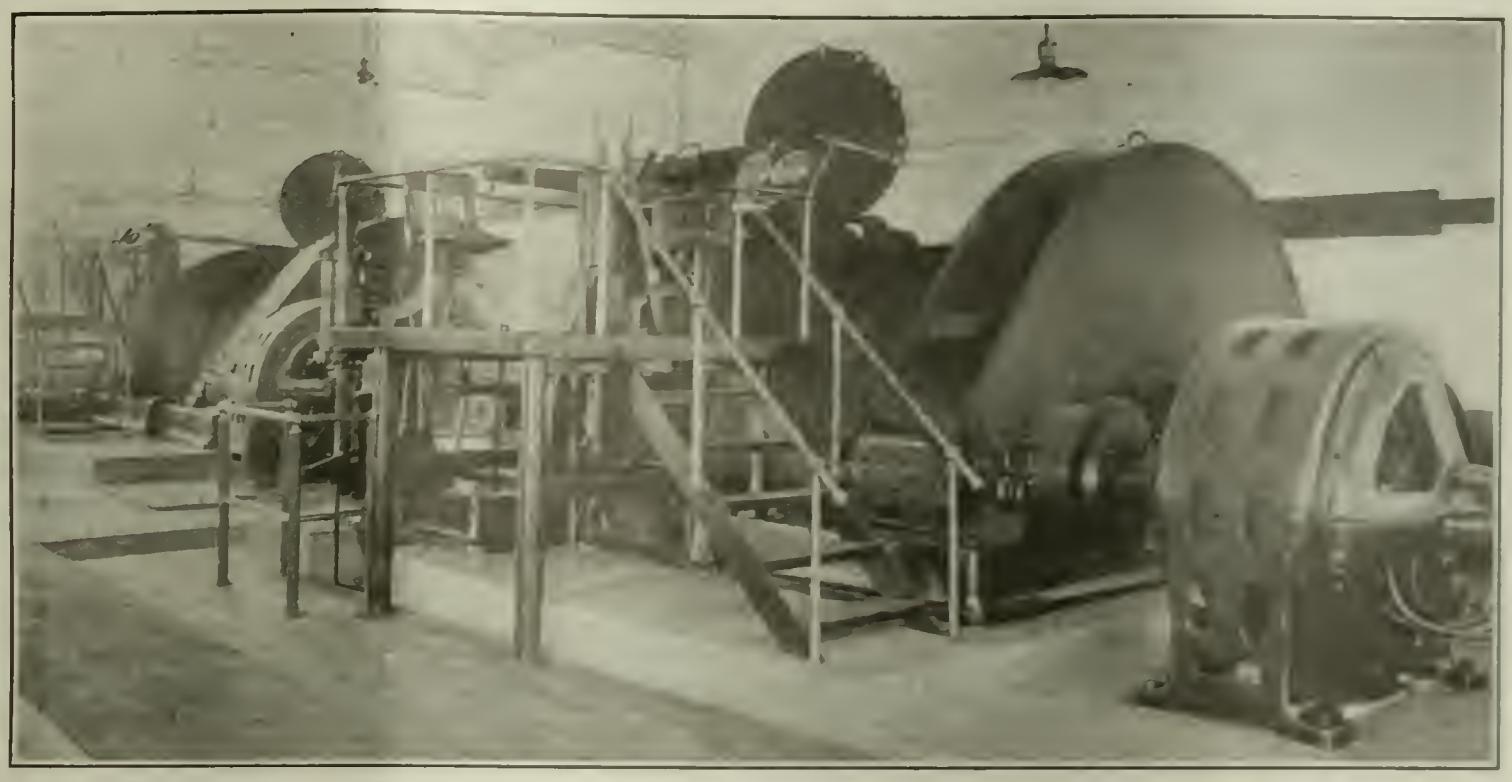
Although brown coal is used mostly in the form of briquets, it can be utilized in other ways. Where it will coke, like the brown coal from Halle, Zeitz and Weissenfels, it may be used in that form. The lignite, having coking qualities, can be readily distinguished from ordinary brown coal. The best coking lignite has a bright yellow, almost white, appearance. When burned it melts like sealing wax and cannot be used at all in grates, as the molten coal would fall between the bars.

This pure and rich coking coal, however, has all been mined. What remains, though more like brown coal, has a lighter color than the non-coking lignite. One of the illustrations shows a pit in a deposit of this character. The lignite is caked slowly so that the water is first separated from it, and later, at a higher temperature, the gases and tar. As a residue a porous and brittle coke remains, which is mostly used for domestic purposes.

The ovens in which the brown coal is baked are vertical shafts lined with firebrick, heated on the outside and provided with rings arranged like shutters, over which the coal slides, losing its moisture gradually. In the hotter part of the shaft the brown coal is decomposed into tar and gas. The coal is taken out at the bottom. The tar is drawn off with the gas and precipitated in a condenser. The gas from which the tar vapors have been extracted serves as fuel for the ovens.

Of the tar, the paraffin, which is extracted by distillation in iron retorts, is the most valuable constituent. By distillation also the oils are freed from the paraffin; those of lower boiling point, forming "solar oil," are freed first. The heavier oils, containing paraffin, are then collected and cooled rapidly, and the paraffin is separated thereby. This is pressed and purified. The oils from which the paraffin has been extracted form cheap lubricating oils and oils for driving Diesel motors.

For some time, especially during the war, experiments were made to increase the production of oils and fuels of high heat value by the distillation of brown coal in producers. The tar in that case is not obtained by a baking process but by distillation. No coke remains but all the combustible materials are transformed into gas. Large quantities of tar were produced by this method during the closing months of the war.



STRIP PIT IN DEPOSIT OF COKING BROWN COAL

The overburden in this pit is noticeably light, though this doubtless has no relation to its coking quality. In America and elsewhere lightly covered coal usually cakes with more difficulty than deeper coal. The coking brown coals of Germany are yellow and even tend toward whiteness. They appear to be possessed of large quantities of paraffin, and they melt so freely in the fire that they serve but poorly under boilers.

Briquetting Room

Pressroom of briquet factory No. 2 of the Victoria Mine. This factory has eight presses each of which in a full day's run of twenty-four hours will produce from 60 to 100 long tons. Thus the whole factory will make from 500 to 900 short tons of briquets daily. Note the troughs by which the briquets move from the machines to the railroad cars, propelled by the pressure of the briquets leaving the machine.

Calculation of Power Required for a Counterweighted Hoist and One in Balance, Shallow Shaft*

Moments Required for Lifting Load Reduced by Moments of Falling Counterweight or Descending Load—Acceleration Moment Must Be Large Enough to Increase Speed of Descending as Well as Ascending Bodies

By F. L. Stone†
Schenectady, N. Y.

IN LAST week's issue shaft calculations were made for an unbalanced, uncounterweighted hoist. In this article will be developed the calculations for a counterweighted hoist and one operated in balance. The counterweight that will give the best motor rating is one the weight of which is equal to that of the cage plus that of the car plus half the weight of the load. In the example given the following conditions were specified:

Total lift, ft.	250
Weight of cage, lb.	9,000
Weight of car, lb.	2,300
Weight of rock, lb.	8,000
Trips per hour	60
Rests, top and bottom, each, sec.	7
Rope	1¼ in. diameter, weight 2 lb per ft.
Drum, cylindrical	6 ft. diameter with 2 ft face
Weight of rotating parts at rope center, lb.	17,000

From these figures it can be deduced that the counterweight for this hoist should weight 15,300 lb. in all. The closer this condition is approximated, the closer will the two cycles, hoisting the load and hoisting the counterweight, coincide.

As 60 trips per hour are required and all other data are the same, the moments of the up load will be exactly the same as in the first case, except for acceleration and retardation moments, which will be increased by reason of the fact that the counterweight has also to be accelerated or retarded.

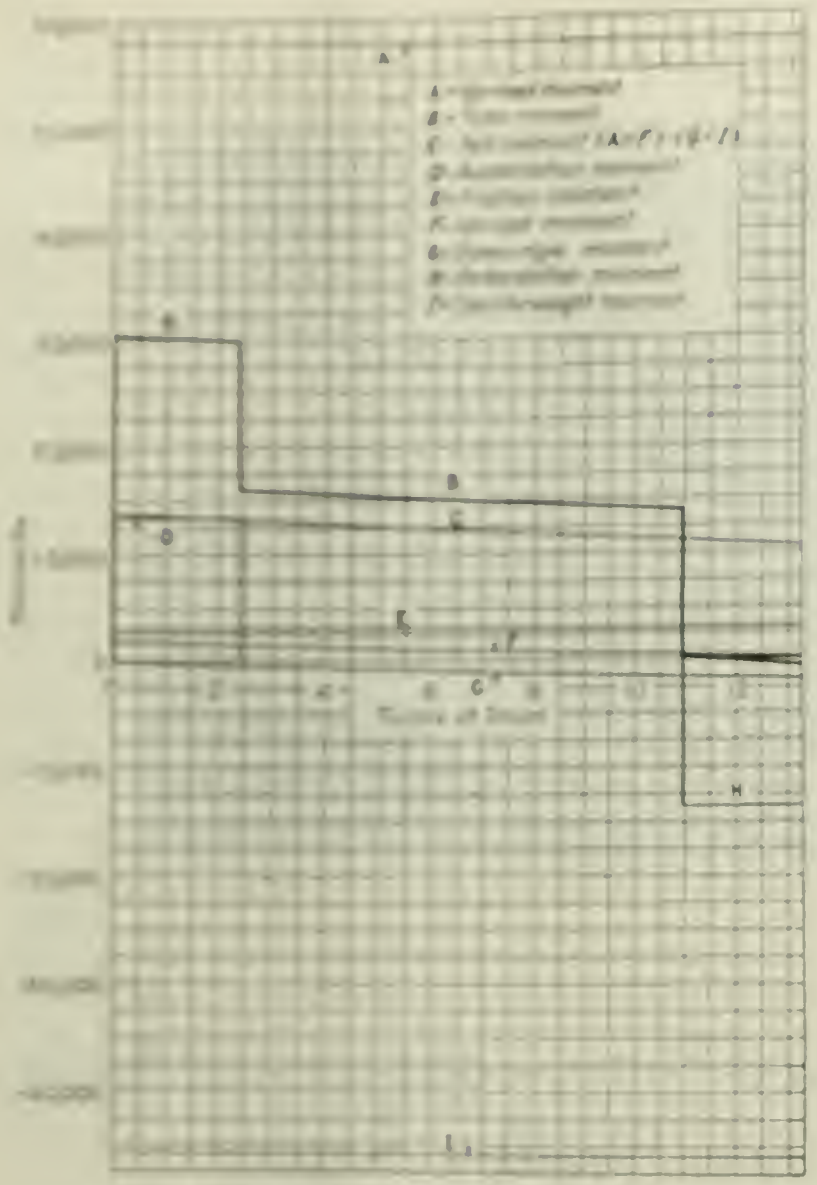
We will, however, proceed as if this were an entirely new problem as far as moments are concerned.

Up Load		
Cage	9,000 lb.	
Car	2,300 lb	
Rock	8,000 lb	
Total	19,300 lb	

Up Moments, Cage and Load	
At 0 turns,	19,300 x 3 = 57,900 ft lb
At 13.26 turns,	19,300 x 3 = 57,900 ft lb

Moments, Up Rope	
At 0 turns,	2 x 250 x 3 = 1,500 ft lb
At 13.26 turns,	0 x 3 = 0 ft lb

Total Up Moments		
Turns,	0	13.26
Load	57,900 ft lb	57,900 ft lb
Rope	1,500 ft lb	0 ft lb
Total	59,400 ft lb	57,900 ft lb
Down	45,900 ft lb	47,400 ft lb
Net	13,500 ft lb	10,500 ft lb



$$\text{Average moments} = \frac{13{,}500 + 10{,}500}{2} = 12{,}000 \text{ ft-lb}$$

Assuming 80 per cent efficiency as before, 12,000 ÷ 0.8 = 15,000 ft.-lb. Substracting the average moment from 15,000 (that is, 15,000 − 12,000) we get 3,000 ft.-lb., which is the frictional moment. The acceleration and retardation may be calculated as follows:

NOTE—The headpiece shows ore and cage hoists at mine of Montreal Mining Co., Hurley, Wis.

*Other articles on hoist design by F. L. Stone may be found in *Coal Age*, Vol. 8, p. 916; Vol. 9, p. 923, and Vol. 22, p. 977.

†Power and mining engineering department, General Electric Co.

MOMENTS WHEN RAISING CAGE AND CAR AND LOWERING COUNTERWEIGHT

The upper block that represents the total moments which are in this case positive, for the retardation moment at no time is sufficient to reverse it necessarily in spite of brake on the engine or to make the use of power for hoist is unnecessary.

Revolutions per second full speed = 0.78

Rope speed = 14.68 ft. per sec.

$$\text{Acceleration} = \frac{14.68}{6} = 2.446 \text{ ft. per sec. per sec.}$$

In this, as in the first case, given in the article last week, p. 577, all the mass is moving at the same speed, including the rotating parts of the hoist, the values of which have been reduced to their equivalent at the rope center. We therefore can take the whole weight moving and determine the acceleration moment at one calculation. The load to be accelerated and retarded may be itemized as follows:

	Lb.		Lb.
Counterweight	15,300	Drum	1,800
Cage	9,000	Drum	17,000
Car	2,300	Head sheave	7,000
Rope	1,800		
Total			60,400

$$\text{Accelerating force} = \frac{60,400 \times 2.446}{32.2} = 4,590 \text{ lb.}$$

$$\text{Moment of accelerating force} = 4,590 \times 3 = 13,764 \text{ ft.-lb.}$$

Retardation, as before, will have the same value as acceleration, but with a negative sign—that is, —13,764.

SUMMATION OF MOMENTS (LIFTING LOAD) IN FT.LB.

Turns	0	2.34	2.34	10.92	10.92	13.26
Car, load and rope moment	13,500	13,200	13,200	10,800	10,800	10,500
Frictional moment	3,000	3,000	3,000	3,000	3,000	3,000
Moment of accelerating force	13,764	13,764	0	0	—13,764	—13,764
Total moment	30,264	29,964	16,200	13,800	1,860	—264
Time	0	5	6	17	17	23
Horsepower	344	340	164.2	122.7	8.3	—2.3

$$\text{Horsepower required} = \frac{2 \times 3.14 \times \text{revolutions} \times \text{moment}}{550} = 0.0089 \times \text{moment}$$

To the lifting of the counterweight and the lowering of the cage and cars the following computations can be applied:

Up Moments		*Down Moments*	
Turns 0	15,300 x 3 = 45,900 ft.lb.	Turns 0	—11,300 x 3 = — 33,900 ft.lb.
Turns 13.26	15,300 x 3 = 45,900 ft.lb.	Turns 13.26	—11,300 x 3 = — 33,900 ft.lb.
Moments of Up Rope		*Moments of Down Rope*	
Turns 0	2 x 250 x 3 = 1,500 ft.lb.	Turns 0	0 ft.lb.
Turns 13.26	0 = 0 ft.lb.	Turns 13.26	2 x 250 x 3 = 1,500 ft.lb.

Sum of Moments Up			*Sum of Moments Down*		
Turn	0	13.26	Turn	0	13.26
Load	45,900 ft.lb.	45,900 ft.lb.	Load	33,900 ft.lb.	33,900 ft.lb.
Rope	1,500 ft.lb.	0 ft.lb.	Rope	0 ft.lb.	1,500 ft.lb.
Total	47,400 ft.lb.	45,900 ft.lb.		33,900 ft.lb.	35,400 ft.lb.
Down	—33,900 ft.lb.	—35,400 ft.lb.			
Net	13,500 ft.lb.	10,500 ft.lb.			

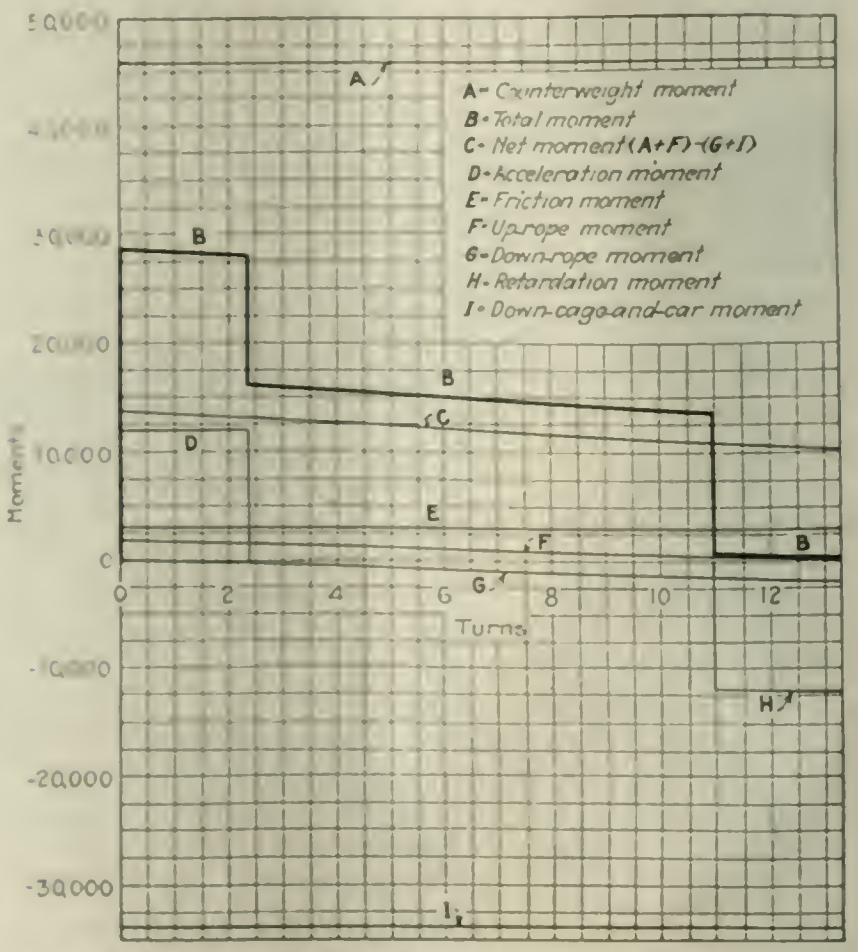
$$\text{Average moment} = \frac{13,500 + 10,500}{2} = 12,000 \text{ ft.lb.}$$

Again assuming an 80-per cent efficiency and dividing by 0.8, the average moment will become 15,000, or 3,000 more than before, making the frictional moment 3,000 ft.-lb. Acceleration and retardation are computed as follows:

Revolutions per second = 0.78 and the rope speed = 14.68 ft. per sec.
Acceleration = 2.446 ft. per sec. per sec. as before.

Load to Be Accelerated or Retarded	Lb.		Lb.
Counterweight	15,300	Drum	17,000
Cage	9,000	Head sheave	7,000
Car	2,300		
Rope	1,800	Total, lb.	52,400

$$\text{Accelerating force} = \frac{52,400 \times 2.446}{32.2} = 3,980 \text{ lb.}$$



Moment of accelerating force = 3,980 x 3 = 11,940 lb.

The summation of moments in lifting the counterweight will be as follows:

SUMMATION OF MOMENTS (LIFTING COUNTERWEIGHT) IN FT.LB.

Turns		2.34	2.34	10.92	10.92	13.26
Counterweight and rope moment	13,500	13,200	13,200	10,800	10,800	10,500
Frictional moment	3,000	3,000	3,000	3,000	3,000	3,000
Moment of accelerating force	11,940	11,940	0	0	—11,940	—11,940
Total moment	28,440	28,140	16,200	13,800	1,860	1,560
Time	0	6	6	17	17	23
Horsepower	253	250	144	123	16.55	13.88

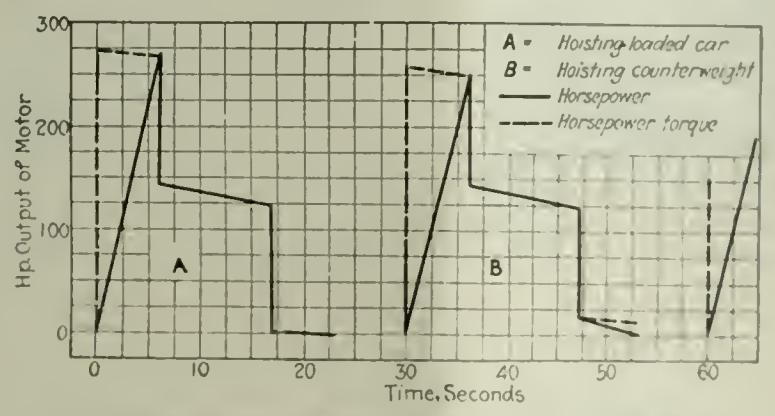
Horsepower = 0.0089 x total moment

MOMENTS WHEN LOWERING CAGE AND CAR AND HOISTING COUNTERWEIGHT

As the counterweight moment is reduced by the moment of the cage and car the total moment is less than the counterweight moment. The net moment equals the difference between the sum of the up-counterweight and up-rope moments and the sum of the down-cage, down-car, down-load and down-rope moments.

Glancing at the duty cycle it will be seen that the motor required for this work is much smaller than that necessary for hoisting a totally unbalanced load. The actual work done is that of hoisting the active load, rock or coal.

We have lifted 8,000 lb. of material through 250 ft., the work being done at an assumed efficiency of 80 per cent.



Work done = 8,000 x 250 = 2,000,000 ft.lb. or

$$\text{Horsepower-seconds} = \frac{2{,}000{,}000}{550} = 3{,}636$$

Then $\frac{3{,}636}{0.8}$ = 4,545 hp. sec., which should equal the area of the total duty cycle. Thus:

	Loaded Car Up	*Counterweight Up*
Accelerating	$\frac{269+266}{2} \times \frac{6}{2} = 802.50$	$\frac{253+250}{2} \times \frac{6}{2} = 754.50$
At full speed	$\frac{144.2+122.7}{2} \times 11 = 1{,}467.95$	$\frac{144.5+123}{2} \times 11 = 1{,}471.25$
Retarding	$\frac{1.07-1.83}{2} \times \frac{6}{2} = -1.14$	$\frac{16.55+13.88}{2} \times \frac{6}{2} = \frac{45.64}{2}$
Total horsepower-seconds	= 2,269.31	2,271.39

Adding the horsepower seconds of work performed in the two cycles—namely 2,269.31 and 2,271.39—the result is 4,540.21, thus checking with the result previously obtained.

HORSEPOWER-TIME CURVE, DUTY CYCLE, COUNTERWEIGHT HOIST

The left graph, A, is that which refers to the hoisting of the loaded car and the right graph, B, that which relates to the hoisting of the counterweight, both being quite similar and differing but little in magnitude.

We will now consider the last case for this set of conditions—namely, hoist in complete balance. That is to say, we will assume a double-compartment shaft, cages and cars in balance and the same output, a trip per minute, as in the first two cases, that just calculated and that considered in *Coal Age* on pages 577 et seq. of this volume.

The up moments of the cage, car, rock and rope will be the same as before, that is, Turns 0 = 59,400 ft.-lb.; Turns 13.26 = 57,900 ft.-lb.

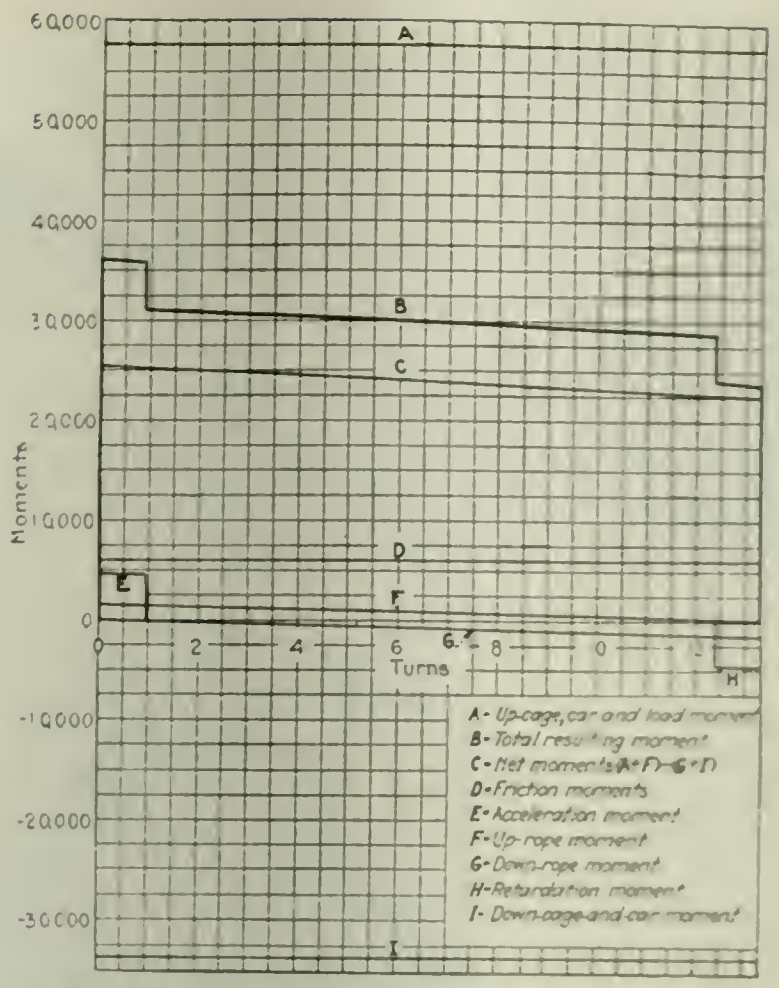
The down cage and car have the following weights: Cage 9,000 lb.; car, 2,300 lb.; total 11,300 lb.

DOWN MOMENTS

Turns 0 11,300 × 3 = 33,900 ft. lb.
Turns 13.26 11,300 × 3 = 33,900 ft. lb.

MOMENTS OF DOWN ROPE

Turns 0 0 ft.lb.
Turns 13.26 2 x 250 x 3 = 1,500 ft.lb.



SUM OF MOMENTS DOWN

Turns 0 33,900 + 0 = 33,900 ft.lb.
Turns 13.26 33,900 + 1,500 = 35,400 ft.lb.

The down moments must now be deducted from the up moments.

Turns	0	13.26
Up moments	59,400 ft.lb.	57,900 ft.lb.
Down moments	33,900 ft.lb.	35,400 ft.lb.
Total	25,500 ft.lb.	22,500 ft.lb.

$$\text{Average net moment} = \frac{25{,}500 + 22{,}500}{2} = 24{,}000 \text{ ft.lb.}$$

MOMENTS WHEN HOISTING IN BALANCE

Here again the total moment, being the algebraic sum of two contrary moments, is less than the larger moment and in fact less than either. The net moment equals the difference between the sum of the up-car, up-cage, up-load and up-rope moments and the sum of the down-car, down-cage, down-load and down-rope moments.

Again assuming an 80-per cent efficiency and dividing by 0.8, the average net moment will become 30,000 ft.-lb., or 6,000 ft.-lb. more than before, making the frictional moment 6,000 ft.-lb. Acceleration and retardation should be determined as follows:

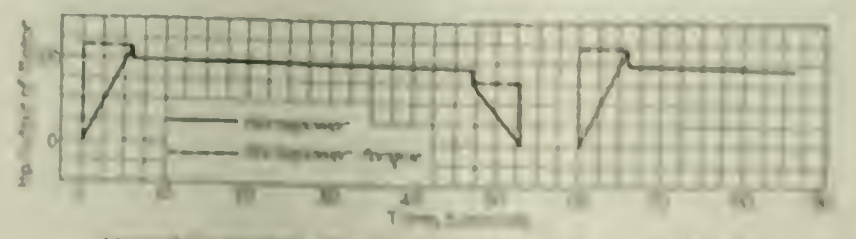
	Lb.		Lb.
Cages	18,000	Drum	17,000
Cars	4,600	Sheaves	7,000
Rock	8,000		
Rope	1,800	Total	56,400

Running time = 60—7 = 53 sec.

The acceleration takes place in 6 sec. and the retardation in 6 sec. as before.

$$\frac{13.26}{53 - \frac{6+6}{2}} = \frac{13.26}{47} = 0.282 \text{ revolutions per second, or } 16.9 \text{ r.p.m.}$$

$$\text{Turns during acceleration and retardation} = \frac{0.282 \times 6}{2} = 0.846$$



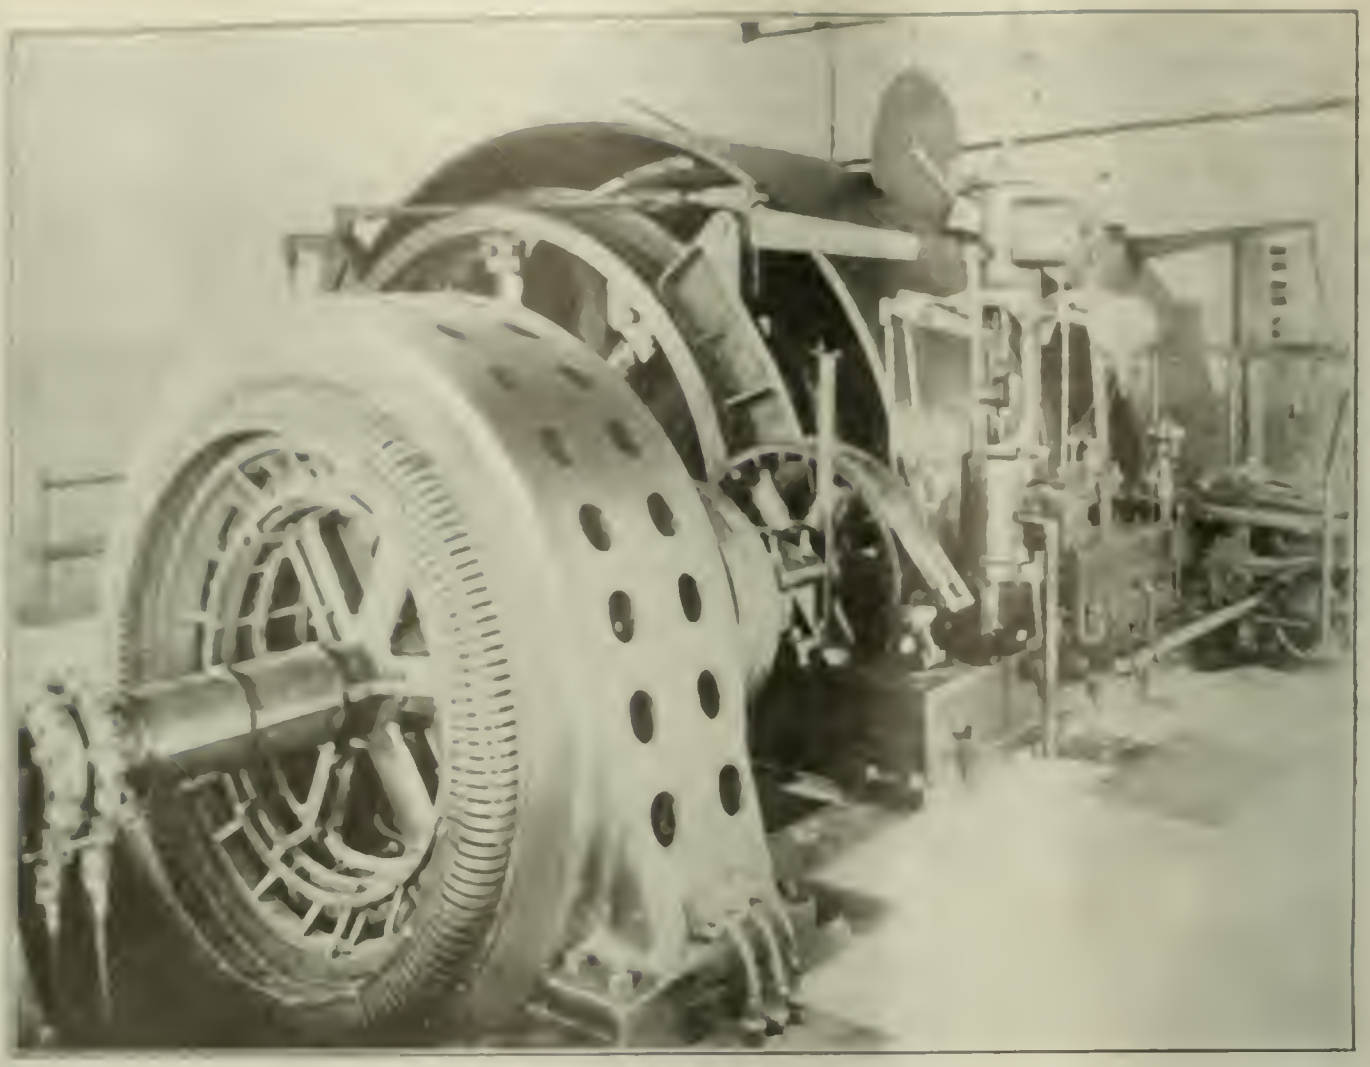
Velocity at full speed = 0.282 x 6π = 5.3 ft. per sec.

$$\text{Acceleration} = \frac{5.3}{6} = 0.884 \text{ ft. per sec. per sec.}$$

$$\text{Accelerating force} = \frac{56{,}400 \times 0.884}{32.2} = 1{,}548 \text{ lb.}$$

Moment of accelerating force = 1,548 x 3 = 4,644 ft.lb.

The summation of the moments for the balanced hoist will be found tabulated on the next page near the top of the left column.



HORSEPOWER-TIME CURVE, DUTY CYCLE, BALANCED HOIST

The solid line represents the horsepower actually used and the dotted line the horsepower that must be provided. No horsepower can be actually used when the rope is not moving, but when the hoist is starting a horsepower torque must be provided as great as at any point in the cycle. A torque somewhat smaller but still large must be provided at the end of the cycle.

Electric Hoist

A substantial hoist at No. 14 shaft of the Lehigh Coal & Navigation Co.'s Lansford, Pa., colliery repairs an 800-ft. lift, and runs at rope speed of 3,000 ft.

SUMMATION OF MOMENTS (BALANCED HOIST)

Point	0	0.884	5.884	12.36	12.36	13.26
Rope moments	23,500	23,250	23,250	22,850	22,850	22,500
Load moments	6,000	6,000	6,000	6,000	6,000	6,000
Unbalanced moments	4,644	4,644	0	0	−4,644	−4,644
Total	34,144	33,894	29,250	28,850	24,156	23,856
Engine speed	116.2	115.3	100.5	92.9	77.8	77
Time	0	6	6	47	47	53

$$\text{Engine speed} = \frac{\text{Drum r.p.m.} \times \text{gear ratio}}{\text{Pitch}} \times \text{(Rope speed} \times \text{constant)}$$

A check on the area of the plotted cycle can be made as follows:

$$\text{Accelerating } \frac{116.2 + 115.3}{2} \times \frac{6}{2} = 347.25$$

$$\text{At full speed } \frac{100.5 + 92.9}{2} \times 41 = 3,964.70$$

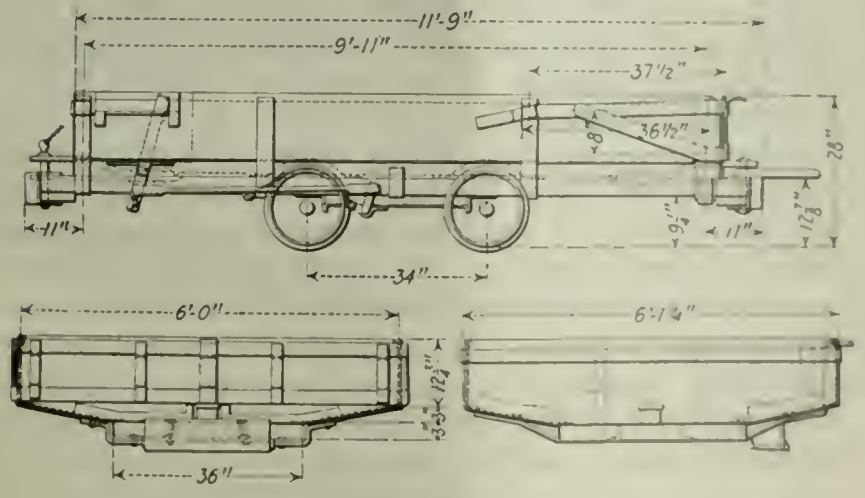
$$\text{Retarding } \frac{77.8 - 77.0}{2} \times \frac{6}{2} = \frac{232.20}{4,544.15} \text{ horsepower seconds.}$$

Is Coal from Peat or from Drifted Matter?

SPEAKING before the British Association for the Advancement of Science Sept. 8 of this year the president of the geological section, Professor Percy Fry Kendall, declared that true coal seams—those, that is, that were autochthonous, or generated where found, that is from peat—had the following characteristics: (1) Wide extent, (2) uniformity of thickness and character over extensive areas, (3) freedom from interstratified detrital mineral matter, (4) constant presence of a seat earth or rootlet bed, (5) entire absence of remains of aquatic animals within the seam. Substitute, he said, negatives for affirmatives and affirmatives for negatives and the characteristics of cannel, which he regards as drift or allochthonous matter, are truly set forth.

In cannel, he added, scales, teeth and bones of fish are almost invariably present, and it is from cannel that our largest collection of coal-measure vertebrates have been obtained. Amphibian remains are more rare; cetraends are crowded in some places and lastly freshwater shells such as Carbonicola are represented commonly not by the shells themselves, but by the flattened wrinkled epidermis, the calcareous shell having evidently been dissolved by the acids generated by decomposing vegetable matter. The ash content always is high, rising to 40 per cent before reaching the point at which it would be regarded as shale. The characteristics of cannel are consistent with the view that it originated from a mass of vegetation macerated in pools of water somewhat after the manner in which flax is retted.

Sometimes the cannel is in unconformable relation to the underlying beds, as at the Abram colliery, Wigan, England, where it rests in one district upon true coal and in the course of about a mile encroaches first on the coal, then upon its underclay and, finally, having become 7 ft. in thickness, it rests upon a bed of shale underlying the underclay.



It commonly happens, added Professor Kendall, that the presence of a patch of cannel as a constitutent of a coal seam is accompanied by an increased thickness, even out of proportion to the magnitude of the cannel, and this irrespective of whether the cannel is above, within or below the true coal. This may be explained by the fact that the process of fermentation by which the cannel was produced reduced its volume more rapidly than the ordinary clay reduced that of the adjacent peat and so maintained a depression in which the plant débris of the peat bog could accumulate, but the ultimate effect of this fermentation was a less complete loss of hydrocarbons, and consequently, both because its contemporaneous loss was greater and its subsequent loss was less, the presence of a cannel component increases the thickness of a seam.

Huntington Show Suggests Modern Ways of Reducing Coal Cost—I

Typical West Virginia Mine Cars — Low Cars Permitting of Side Loading — Use of Band Brakes — Machine for Electrically Heating Rivets—Hoist for Long Slopes and Inclines

MUCH interest was exhibited in the Coal and Industrial Exposition held at Huntington, W. Va., Sept. 18-23, in the Chamber of Commerce Building. Lightning, it is said, seldom hits twice in the same spot, but the coal exposition has ventured for two consecutive years to descend on so small a town as Huntington. The rest of the country needs some of the enlightenment that has been so generously bestowed on this West Virginia town and it is certain that some other city will get it, as it was decided at a meeting of exhibitors to hold the show elsewhere in the coming year. The West Virginia-Kentucky Association of Mine, Mechanical and Electrical Engineers, thus deserted by their exposition, decided to withhold a decision on next year's place of meeting till they found where the exposition was going to be held.

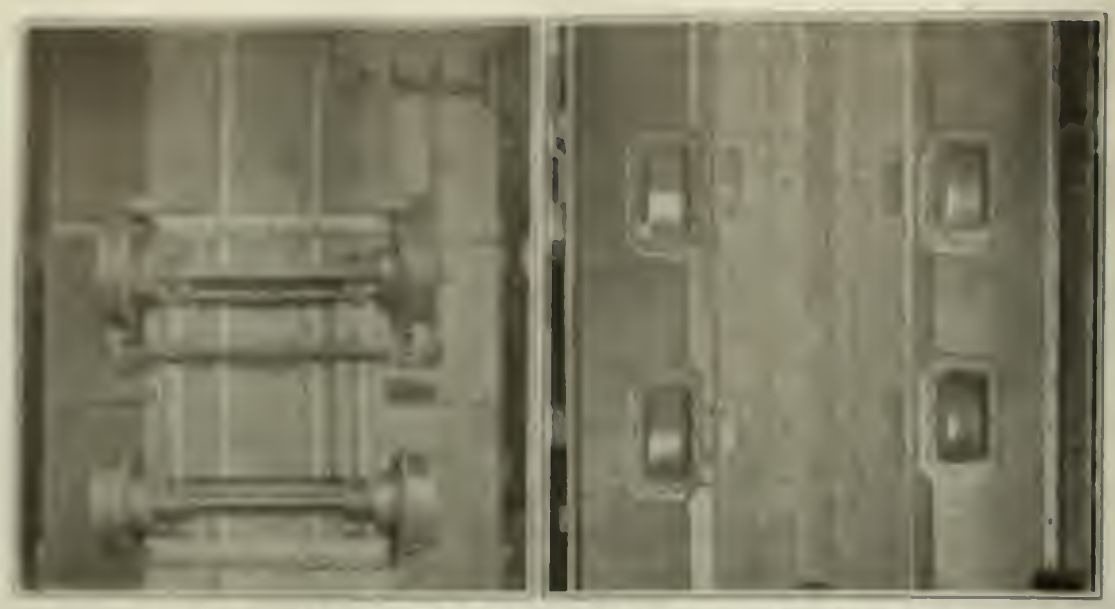
LOW STEEL CAR WITH END GATE AND BAND BRAKE

The top side plate and rear-end plate are of ⅝-in. steel and the flare, gunnel and front-end plates of ¼-in. steel. The capacity is 76 cu.ft. The track gage is 42 in. Hyatt roller-bearing wheels are provided.

Prominent among the exhibits were four mine cars of mammoth proportions. They probably will carry but little coal, however, for apparently payment of coal by the carload instead of by the ton results in the filling of cars but little more than level full. The cars are, however, constructed to carry a maximum quantity of coal for a minimum height of body.

The American Car & Foundry Co. had a big all-steel car that was constructed for the Little War Creek Coal Co., at Iaeger, W. Va. Its weight is 4,400 lb., its length is 9 ft. inside and 10 ft. 8 in. over all, its width is 6 ft. and its height from the top of the rail to the top of the car, 3 ft. 2¼ in. Its capacity is 107 cu.ft. and its gage 44 in. The wheels, which are fitted with Hyatt roller bearings, project above the bottom of the car and are hooded with steel covers; to stiffen the sides three steel gusset plates are set on each side. They connect the sides of the car with its bottom. It will be dumped on a rotary dump.

Across the way might be noted a rival car constructed by the Kenova Mine Car Co. for the Red Jacket Consolidated Coal & Coke Co., at Red Jacket, W. Va. This, which was a composite car with sides of steel and a bottom of wood, like the other, had hooded wheels and two angle stiffening plates on each side. It holds 2½ tons when level full. Its dimensions are as follows: Weight, 3,800 lb.; inside length, 10 ft. 6 in.; width, 6 ft.; height above rail, 29 in.; capacity, 90 cu.ft.; wheels, 14 in in diameter; track gage, 48 in.; wheelbase, 40 in. A spring drawbar, a swivel hitching and a Timken roller-bearing wheel of the exposed lynch-pin type were notable features.



Only slightly smaller is the car made by the Watt Mining Car Wheel Co. for the Island Creek Coal Co. This car has a gage of 44½ in. for a track gage of an even 44 in. It has an 18-in. wheel, a straight link hitching, Hyatt roller bearings and lifting end gate being intended, unlike the other two cars, for end dumping. Its weight is 3,700 lb., its inside length 9 ft. 1½ in., its over-all length 10 ft. 6¼ in., its inside width 5 ft. 5 in., its height above the rail over all 3 ft. 4½ in., its wheel-

SAME CAR SHOWING HEAD END AND BAND BRAKE DETAILS

The introduction of steel has made possible a [illegible] of the car. The rise of the flaring sides of copy 3 in. over the [illegible] width it gives to the car body an [illegible] With a track gage of only 2 ft. 8 in. the [illegible] of the car is 6 ft. It can be hauled equally well at the side, the front and the end.

NOTE—The illustration forming part of the title depicts the booth of the Northeast Kentucky Association which was a reproduction of the mouth of a mine in that section. The men grouped on the car were a number of anthracite mine workers who, dressed in overalls and mining caps with [illegible] lamps, provided a large part of the excellent musical entertainment which enlivened the exposition.

CODE OF CAR BOTTOM FROM BELOW AND FROM ABOVE

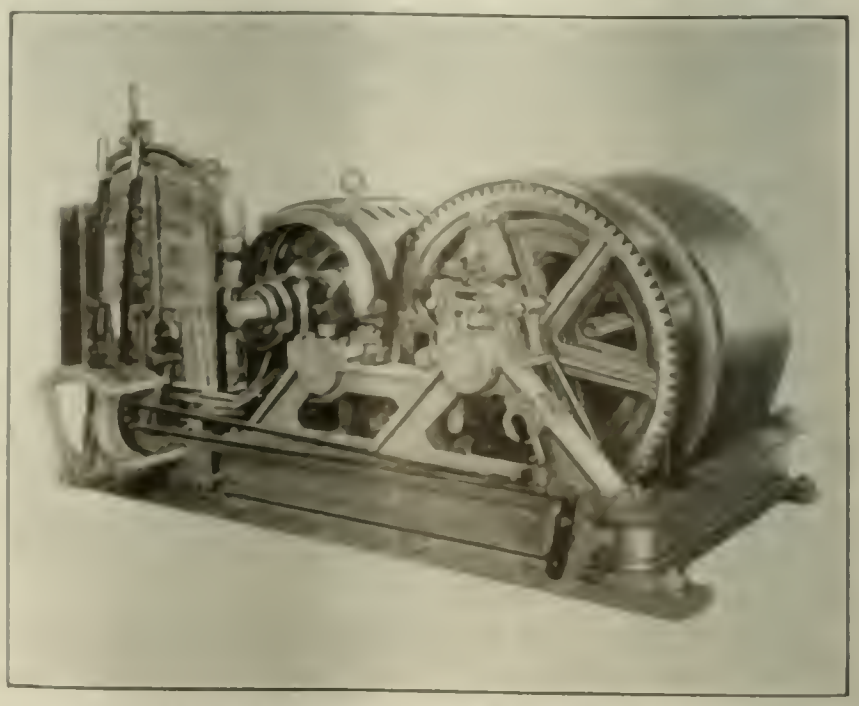
This view was in that from below and shows the hand brake on the hind wheels. The second view is that from above. It shows the housings over the wheels. The tops of these wheels are actually above the level of the car bottom. As the car is flat and dumping no grooves can be provided on the inside

base 32 in. It holds 24 tons when level full and 2.8 tons when loaded to a normal height.

It will be noted that modern mine cars are frequently riveted; not bolted. Rivets are less likely to become loose. Properly driven, they will hold permanently until a wreck of some sort subjects them to strains for which they have not been designed. Then the cars come to the shop, and the riveting must be renewed.

In this work the electric riveter of the American Car & Foundry Co. exhibited in the company's booth offers opportunities. The heat is, of course, not of the cheapest but it is confined to the rivet and not dissipated as in a furnace. There is no risk of burning a lot of rivets by leaving them in the fire. The heat is from the center out and not from the outer surface inward. Hence it lasts longer or else does not have to be made so intense to last as long. The rivet is in full view of the operator.

In a booth near the entrance to the show was exhibited, by the Hockensmith Wheel & Mine Car Co., a car built for the Pond Creek By-Product Collieries Co., of Leekieville, Ky. Several illustrations are shown of it because, although it has certain qualities all its own, it is typical of the cars being used in West Virginia, a state where large loadings per man are made at most of the mines. The cars are quite low, this one being only 28 in. high. The height is kept low, usually not at all because the coal is thin, but because ease of loading favors a low car. It also saves injury to the coal in loading.



The band-friction double-reduction single-drum hoist of the Thomas Elevator Co. occupied another booth. It is intended for such work as sinking shafts, hauling cars up slopes or inclines or for other purposes where a machine with large drum and ample cable capacity is desired. It is fitted with a band friction on one end of the drum and a composition-lined band brake on the other. A band friction puts no end thrust on the bearings and is therefore especially advantageous on long hauls. The brake is of ample proportions and as it is placed on the opposite end of the drum from the friction any heat generated by it does not affect the operation.

These machines are furnished with a smooth drum face and cut gearing. When made with machine-cut grooves on the drum the friction may be locked in engagement and the machine used for operating skips, cages or cars in balance. The brake and friction shafts are fitted with babbitted bearings and the control levers are banked in a quadrant conveniently located for the operator. Speeds and capacities range up to 12,000 lb. rope pull and 600 ft. per minute. Either alternating or direct current may be employed.

HEATS RIVETS BY RESISTANCE TO CURRENT

Coal, gas, smoke and cinders have been avoided by the use of this electric rivet heater that handles three rivets at a time. The rivets are heated by conducting the current by the bar or rods along the work. Rivets should not be heated to over 1,800 deg. Fahr. The core of an electrically heated rivet is hotter than the surface. When heated in this manner it should not be dropped in a wooden box. It would seem that steam-chilled lithe weight to advantage before the rivet cools.

BAND-FRICTION SINGLE-DRUM HOIST

Has a band-friction brake at one end of the drum and composition-lined band brake on the other. A band friction puts no end thrust on the bearings and is therefore advantageous on long hauls.

Every Big Mine Should Have Its Locomotive Inspector

To Be Always "Fit" a Locomotive Must Be Inspected at Regular and Frequent Intervals—If Continuously Kept in Good Condition, with Hauling Loads Commensurate with Capacity, It Should Last Indefinitely

By W. M. Johnson*
Woodward, Ala.

ELECTRIC locomotives are now largely employed both in gaseous and non-gaseous mines for hauling coal from the working face to the pit mouth. These machines form the key to present-day coal production. They vary in size from four to thirty tons. Without them the output of some of the larger mines would be so seriously reduced that coal could not be mined economically. In fact to revert to mule haulage or other modes of transportation would mean disaster to the coal-mining industry.

Considering the thousands of electric locomotives that are put into the mines each year, the question naturally arises what percentage replaces worn-out equipment and what is installed in new development? This is not easily answered, as other considerations are immediately involved such as "What is the average life of a mine locomotive?" as well as many others.

Of course everyone experienced with mine locomotives will immediately answer that the life of an electric haulage motor depends entirely on the service it is called upon to perform. They believe that they have thus effectively answered the query. However, even if we restrict the scope of the question and limit the work of the locomotive to that commensurate with its size, so that the machine hauls loads proportionate to its capacity only and over track such as is normally found in coal mines, the question is not easily answered in a satisfactory manner.

Ancient Locomotives Are Rarely Seen

From time to time the technical papers have published photographs of electric locomotives of ancient vintage that have been in continuous service for twenty or more years and that are still as good as new, or are doing as much work as ever. Here again is an answer to the query, but is it not rather the exception than the rule that a locomotive should operate for twenty years and be as good as ever, without any change in structure, or with little or no expense for repair parts during that time?

As a matter of fact, coal company records of cost of operation and repairs to electric locomotives are for the most part average costs and cannot be used in a comparative way to estimate the life of such a machine. Neither can a yearly depreciation method be employed.

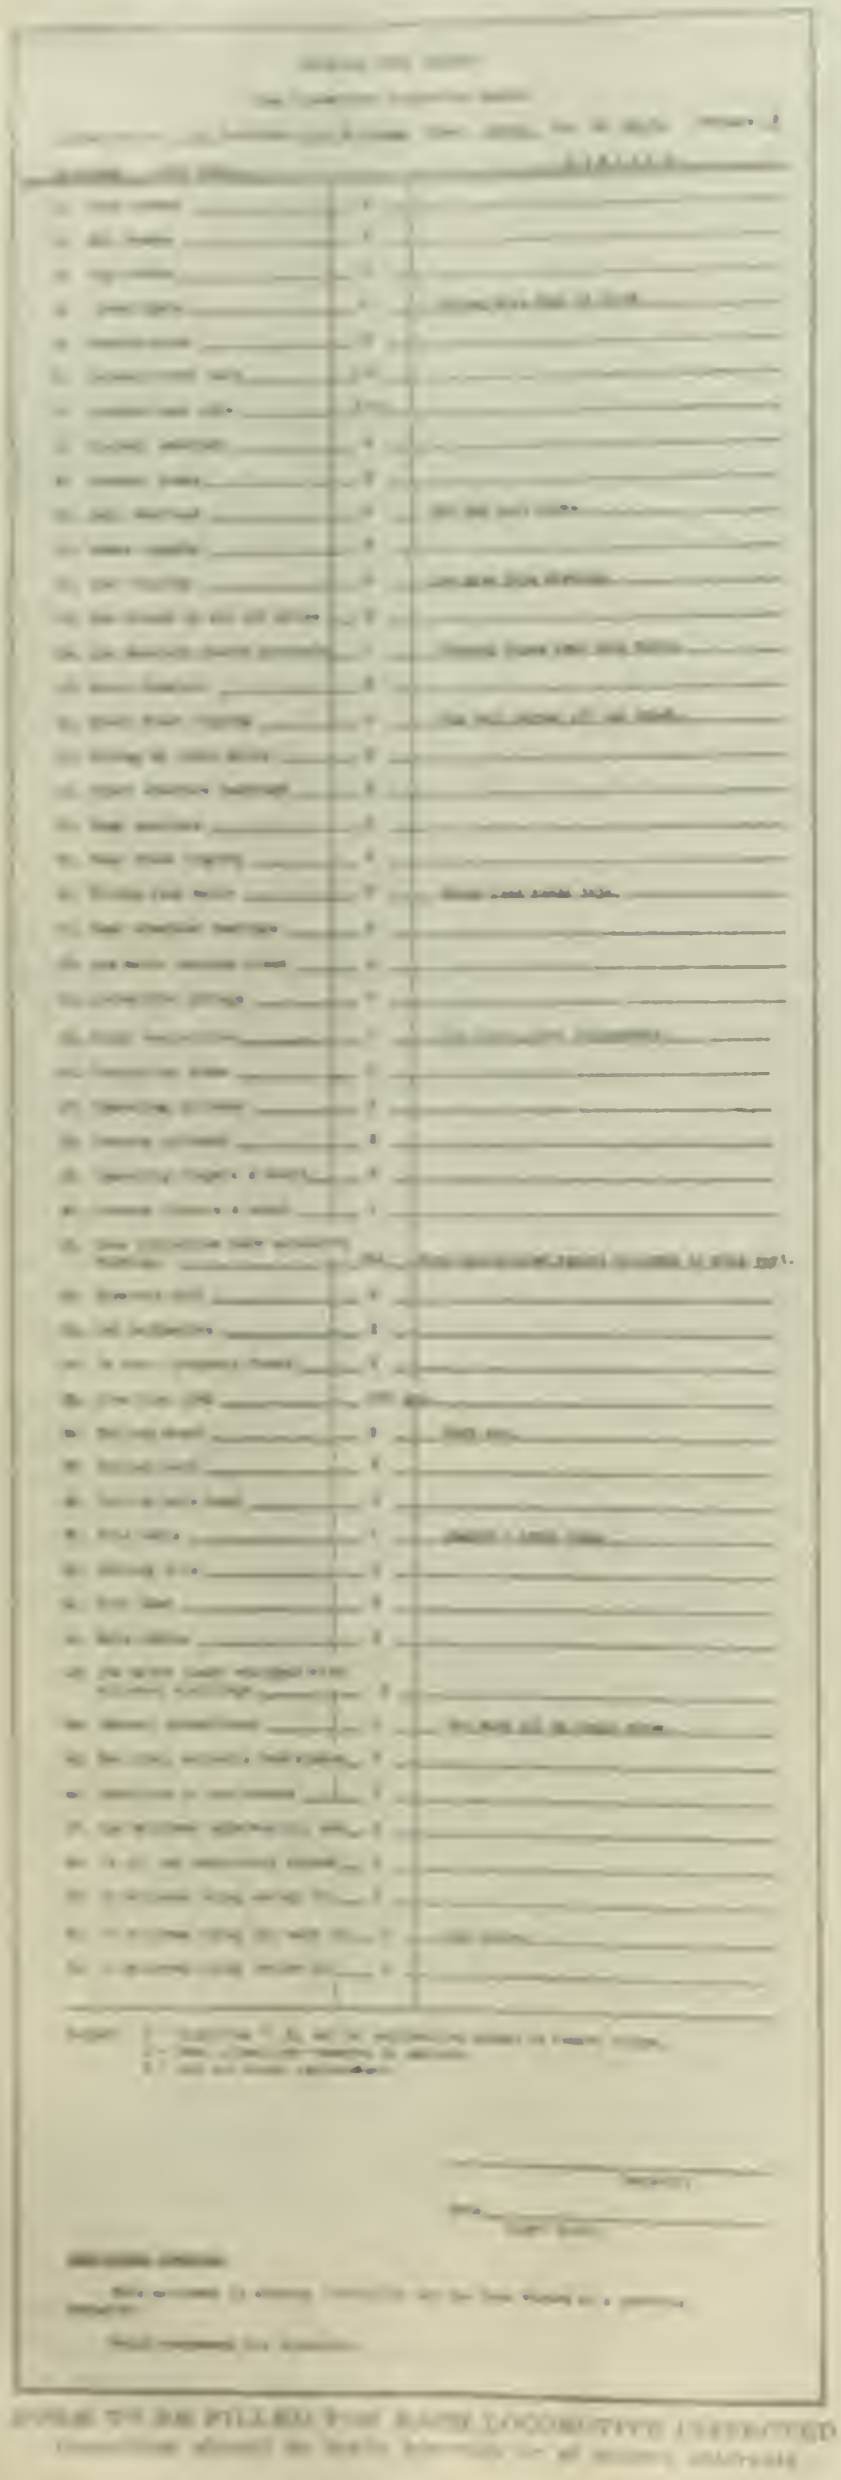
Again if new parts are being continually added to a locomotive, is it fair to estimate the life of the machine at twenty years, when as a matter of fact probably twice the cost of a new haulage motor or a capitalization amounting to the price of three locomotives has been spent during this period and its end finds the company possessed of a half or completely worn-out locomotive?

On what then does the life of an electric locomotive operating at normal load and over average trackage depend? The answer is: "On the thoroughness and regularity with which it is inspected and the promptness and excellence of the repairs made." The old adage, "It is easier to keep up than catch up," applies particularly to electric mine-haulage locomotives.

Consider your own mine. Are the electric locomotives used in it always in first-class condition, or are they over the pit a large part of the time? Is it cheaper to operate them in a hit-or-miss fashion until they go out of service for want of repairs, with the accompanying interruptions to haulage schedules and loss of tonnage or to keep them in such shape that they will maintain a 100-per cent efficient haulage schedule?

Railroad Locomotives Rigorously Inspected

Look at the great steam-railway systems on which the very existence of the country depends. Are they run in a hit-or-miss fashion? Decidedly not. A fast freight or passenger locomotive after a run of 100 or 200 miles is thoroughly examined, oiled and passed by competent inspectors before it is again called upon to perform service. Are electric mine locomotives, many of which travel 100 miles per day and some of which cover an equal distance both day and night, treated in a similar manner? Or are they run until they fall apart? Again I affirm that "the life of an electric locomotive varies directly as the completeness of inspection and the quality of repairs made."



Most mine owners will say: "Of course we inspect our electric locomotives. Our mine electrician both inspects and repairs them. In fact he does everything but operate them, and he could do that if necessary." But should the man who makes the inspection be the one to make the repairs also? Emphatically not. Man's characteristic tendency to do as little physical work as possible and "get by" is the reason for so saying.

Electrician Should Not Inspect Own Motors

The old biblical admonition to the effect that "a man can see the mote in his neighbor's eye but cannot see the beam in his own eye" is familiar to all. The same reasoning applies to permitting an electrician to make his own inspections. He soon will be making his inspection reports to suit his own convenience. And a report that does not embody a true statement of conditions is of less value than none at all, for it will convey an erroneous impression to the management.

In large operations with twenty or more electric locomotives in service an inspector is a necessity and will save his wages many times over in the course of a year. In the case of smaller companies working one or two mines and employing only a few locomotives, the proper scheme is to have the electrician from one mine act as the inspector for the other and vice versa. With a little friendly rivalry, it will be surprising to see the close scrutiny the locomotives will receive and to observe how delays, armature failures and kindred

*Electrical Superintendent, Woodward Iron Co.

troubles will decrease slowly and steadily until, instead of being an accepted daily occurrence, they will become unusual.

An inspector, where the mines operate daily, can handle about twenty locomotives per week as a maximum allotment, provided those machines are not scattered over too great a territory. He can report on each machine twice weekly. My inspector handles thirty locomotives per week equally divided between three mines. He works 10 hours per shift at night, six nights per week. He can thoroughly inspect, on the average, eight locomotives per shift, so that each week I have on my desk a complete statement of the actual condition of each machine. The mine electrician also receives a carbon copy of the inspection report the morning following. In this manner no time is lost in replacing any parts found needing attention.

To make the work of inspection as easy as possible, especially so far as writing is concerned, a printed form has been prepared arranged in pads so that a carbon copy is easily made. The form accompanying this article is an actual copy of an inspector's report. As may be seen, it requires little writing, yet conveys a complete record of conditions. These reports are likewise easily examined, as the status of any part requiring attention stands out prominently while that of those in good shape is automatically passed over at a glance.

This form is intended for use with a straight two-motor locomotive without reel attachment. It can easily be modified to meet the needs of any type, however, using the same symbolic scheme to reduce to a minimum the writing that the inspector is obliged to do.

I adopted this inspection system about a year ago. At that time one of our mines was producing 1,400 tons of coal per day with twelve locomotives in service. These machines were continually in and out of the pit for the renewal of armatures burned out by poling, for hot bearings, controller and brake trouble and numerous other misfortunes peculiar to electric mine locomotives. At the present time the same mine operates only nine locomotives, yet produces 2,300 to 2,400 tons per day. During the past six months not a single armature has failed, whereas prior to the adoption of this inspection system an average of one to two locomotive armatures were burned out per week. The same inspection scheme has been adopted for our coal-cutting machines, and the results obtained in the past half year have been highly gratifying.

How long will a locomotive last in mine service? At the present time we cannot estimate the life of our machines. As we are keeping them in first-class operating condition they should last indefinitely.

BY THE INSTALLATION of means for the control of air currents, by the installation of instruments of precision and by making a long series of calibrations, the experimental coal mine operated by the U. S. Bureau of Mines at Bruceton, Pa., near Pittsburgh, has been put in condition for a study of some fundamental factors that govern the ventilation of mines. In one of the rooms of the mine a lead disk 3 ft. in diameter has been placed against the coal. Thermocouples have been placed in this disk and also at various depths in the coal and shale roof for the purpose of studying the rate of flow of heat through coal and shale. Such data, when obtained, will be of value in the control of ventilation in deep metal mines. This work is under the general direction of G. S. Rice, and under the personal supervision of J. W. Paul, assisted by G. E. McElroy, H. P. Greenwald and H. C. Howarth.

American Mining Congress Considers Standardization, Taxation and Industrial Relations

Twenty-Fifth Annual Convention Held in Cleveland—Coal in Limelight —Seek Laws to Prevent Interference by Organizations of Employers or Employees with Production or Distribution of Necessities of Life

COAL was easily the headliner at the twenty-fifth annual convention of the American Mining Congress in Cleveland, Oct. 9 to 14. The cataclysmic events in coal's history during the past year and the present general movement, both internal and external, to reorganize the coal industry are responsible. During the five days of the convention, held in connection with a striking national exposition of mining methods and equipment in Cleveland's new and magnificent Public Auditorium, much was said which may have a lasting effect upon coal and its relations with the public. The convention program directed much attention to standardization throughout all mining, upon mine taxation, better industrial relations within all branches of the industry, and to oil shale and its future, but there is no gainsaying the fact that coal was in the spotlight.

Sidney J. Jennings, of New York, was elected president; D. B. Wentz, of Philadelphia, first vice-president; H. W. Seaman, of Chicago, second vice-president, and E. L. Doheny, of Los Angeles, third vice-president. Directors elected were D. B. Wentz, W. C. Doring, president of the Southern Wheel Co.; W. H. Lindsay, of Nashville, and A. J. Nason, of Chicago. The convention and mining exhibition in 1923 will be held in Milwaukee.

At the closing session on Friday the convention adopted a ringing resolution on the labor question, declaring that "laws should be made and enforced by all the power of the government that shall forever strip labor organizations as well as employers of the ability to interfere with production and distribution of the necessities of life." A resolution was adopted putting the influence of the American Mining Congress behind the Federal Coal Commission and authorizing a committee of seven from the congress to co-operate with the commission and with the coal operators.

Crowds Flock to New Auditorium

The convention and exposition drew mining men and others interested less directly from all over the country. A total of over 500 delegates registered but the throngs which flowed through the two immense floors almost full of exhibits in the Public Auditorium when the doors were open to the public would have indicated a much greater attendance. Cleveland itself contributed heavily to this crowd, for the great building is new and most of the taxpayers whose $6,500,000 built it have not yet seen its beautiful and spacious interior. It was generally admitted by exhibitors that they had never shown before in such a handsome and well-appointed building. Many of their displays were novel and most of them interesting and instructive.

Delegates began to register for the convention as early as Sunday morning, Oct. 9. The next day enrolment boomed as engineers and mining men arrived from everywhere. Short meetings of the boards of governors for the Southern and the Western divisions of the congress were the only program events of the morning, but in the afternoon the taxation conference, one of the important branches of the congress, began its series of meetings, which ran through the succeeding three days.

Monday evening the convention and exposition was formally opened with a program on the immense stage of the auditorium after a musical prelude on the municipal pipe organ played by Edwin Arthur Kraft and songs by Miss Rex Haller, soprano, and the famous "Anthracite Quartet" of hard-coal miners from Pennsylvania.

Newton D. Baker, Secretary of War during a part of Woodrow Wilson's presidency and now president of the Cleveland Chamber of Commerce, made the address of welcome, in which he declared than an obligation rests upon those in the mining industry to devise means of co-operating with each other, to take the public into their confidence, especially in matters relating to coal.

President Harding, unable to be present, sent a letter to Michael Gallagher, of Cleveland, chairman of the speakers' committee for the convention, in which he assured the mining industry of his interest in it and his confidence in the wisdom and leadership of the congress. The President's letter is shown in another column.

Most of Tuesday morning, when the second general conference of the convention was held, was devoted to the interests of metal mining. W. R. Woodford, president of the Rail & River Coal Co., presided. W. J. Loring, president of the congress, who was scheduled for an address, was absent, serving on a committee investigating the Argonaut mine disaster in California. Carmi Thompson, vice-president of the Tod-Stambaugh Co., of Cleveland, iron ore operators, and now a candidate for Governor of Ohio, spoke on "Some Requirements of the Iron Ore Industry." Gold was treated by H. W. Seaman, of Chicago, Ill., and Bruce C. Yates, of Lead, S. D., and a paper on prospecting methods was read by Walter H. Trask, of Denver, Col.

In the afternoon the first of the convention series of oil-shale conferences, presided over by Victor C. Alderson, of the Colorado School of Mines, was held, running parallel with the second mine taxation conference and the first of the standardization conferences. That evening the general session was devoted to "Industrial Co-operation," with John A. Penton presiding.

The principal address of the evening was delivered by

SIDNEY J. JENNINGS
President American Mining Congress, 1922

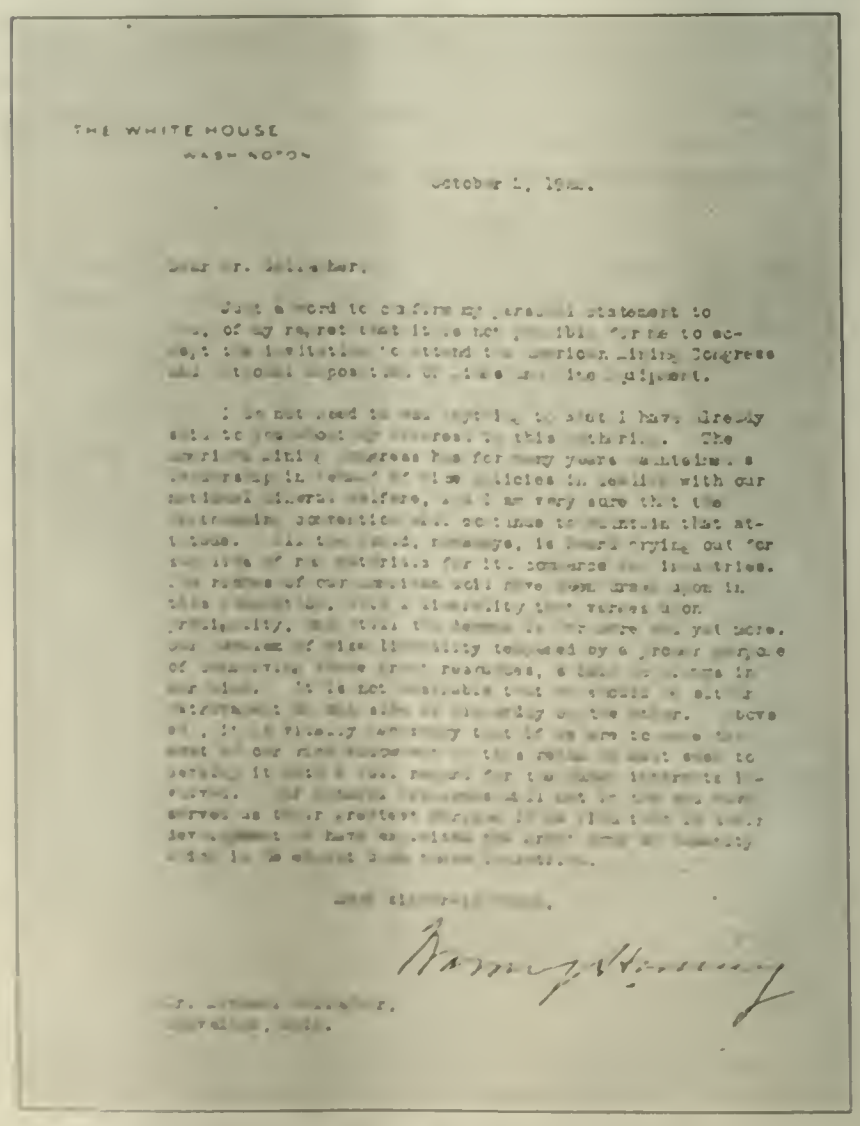
CHARLES D. WENTZ
Re-elected First Vice-President, American Mining Congress

W. A. Grieves, vice-president of the Jeffrey Manufacturing Co., of Columbus, Ohio, a man well known for his firm belief in the value of encouraging a spirit of mutual helpfulness and confidence between employer and employee. He urged his hearers among employers of labor to remember the importance of the human element in their industry and to turn it to good account by educating their men in the principle of mutual dependence. He said unions have their place and should not be antagonized unnecessarily, but that their baneful effect can be offset by proper methods and a wise attitude by men in the head offices and down the line.

Arthur Young, vice-president of the International Harvester Co., described the works council system his company uses throughout its twenty-four plants, declaring that in three years only five appeals had been taken from the decisions of the joint council of workmen and bosses.

An important coal conference took place Wednesday morning, as reported elsewhere. The manufacturers' division of the congress lunched together that day at noon. In the afternoon both the mine taxation and the shale-oil conferences continued.

Wednesday evening, amid much jollity, the exhibitors held a smoker in a temporary dining room at one end of Machinery Hall, the lower floor of the auditorium. A troupe of entertainers, including an orchestra, a cartoonist, a dozen singers and dancers, and two black boys who sang and danced and farced humorously on a big platform in the center of the room were much applauded.



Standardization was given the floor on Thursday. Committee reports, the naming of which does not convey the interesting nature of their contents, occupied most of the day and evening sessions, but led to the exclusion of several addresses by prominent men.

Colonel L. H. Douglas, who, as chief of the technical staff of the ordnance bureau of the War Department, passes on all matters of standardization, spoke on the afternoon on "Standardization as a Factor in Industrial Mobilization." He advocated a draft law for war times that would take in every man from banker to laborer and a scheme of fixing wages and profits that would "freeze wages and profits at figures obtaining when war was declared." That evening W. S. Culbertson, of the Tariff Commission, explained the new act, saying that in his opinion the provision permitting the President to change the schedules and make adjustments would do more to take the tariff out of politics for good than anything that has ever been done. Judge Crawford, of the Industrial Relations Court of Kansas, told of the progress made by that novel experiment in handling labor trouble and pointed to Alex Howat in jail as what they do in Kansas to stop strikes.

G. A. O'Reilly, vice-president of the Irving National Bank of New York, on Friday morning painted an optimistic picture of business conditions in this country and put himself on record as favoring the payment by European countries of their debts to the United States. F. W. Fenn, of the National Automobile Chamber of Commerce, spoke on the importance of motorized transport in mining. Herbert Wilson Smith, of the Mining Congress staff, spoke on the relation of a protective tariff to the mining industry. Friday afternoon was devoted to viewing the exhibits and to dressing for the banquet that night.

The banquet, always a feature of the annual gathering of the Mining Congress, was a gay affair, despite the muchly mentioned and greatly bemoaned absence of pre-Volstead refreshments. The toastmaster, Richard F. Grant, of the M. A. Hanna Co., wove his opening remarks around the old familiar saying, "Gone are the days." After he had everyone saddened he turned Elisha Lee, vice-president of the Pennsylvania R.R., loose. Mr. Lee reviewed the shopmen's strike and said that decentralization of the labor problem offered the only permanent solution. He urged that when a man entered the railroad service he give up the right to strike, and pointed out that the stockholder never has a strike when his earnings fall lower than he likes.

Ira E. Robinson, of the Interior Department, gave the assembly what he described as a "good, old fashioned" talk in the old Fourth of July, spreadeagle style, deprecating every modern tendency and extolling the Constitution and the liberty-loving patriots of the past.

THE WHITE HOUSE
WASHINGTON

October 2, 1922.

My dear Mr. Webster:

Just a word to confirm my previous statement to you, of my regret that it is not possible for me to accept the invitation to attend the American Mining Congress which is to meet in Cleveland.

I do not need to say that I am heartily in accord with what I have already said to you about the importance to this country of the work which the Congress has for many years undertaken, and I am very sure that the patriotic convention will continue to maintain that attitude. In the world, nowadays, is heard crying out for the products of raw materials for its commerce and industries. The resources of our American soil have been drawn upon in this connection, with a generosity that varies with the fertility, but still the demand is for more and yet more. Our concern at this liberality is tempered by a proper purpose of conserving these great resources, and that is borne in mind. It is not unreasonable that we should exert ourselves to this end in preference to the other. Above all, it is vitally important that if we are to make the most of our mine resources we should have a policy which shall be helpful to the miner, for the latter interests [illegible] involved. Of course [illegible] but in the end must serve as their greatest [illegible] if we [illegible] development we have [illegible] and [illegible] in the short [illegible] interests.

And sincerely yours,

Warren G. Harding

Mr. Herbert Hoover,
Cleveland, Ohio.

LETTER FROM PRESIDENT HARDING
Chief Executive's message to the twenty-fifth anniversary of the American Mining Congress, Cleveland, Ohio, Oct. 9-14, 1922.

How Remedy Tax Evils That Beset Mine Properties?

Keen interest in mine taxation was well sustained throughout the twenty-fifth annual convention of the American Mining Congress at Cleveland, Oct. 9 to 14. In the series of taxation conferences running through the first three days the troublous question of how to remedy tax evils which exist in most mining regions was threshed out from many angles, and committee reports, some of them voluminous, were read. As a general result the congress veered its course from state action to federal, on the theory that while the root of a good deal of the evil in mine taxation may be local the first remedy lies largely in the federal government.

So the congress after resolving that the load of federal expenditures be greatly reduced, realigned itself for future taxation activity. A committee is to be appointed made up of at least one well-informed representative in each mining territory to act with the division of taxation so as to better maintain the congress' contact with tax matters everywhere, and the division is to proceed with the collection of a comprehensive library on the subject, to be maintained at Washington headquarters. Already a bibliography has been compiled by McK. W. Kriegh, chief of the tax division, which will be used as a basis for the building of the library.

The congress considered it a healthy sign of federal right-mindedness that two government officials were sent to the tax conferences to encourage better co-operation between mine owners and Washington. E. H. Batson, deputy commissioner in charge of the income tax unit of the U. S. Bureau of Internal Revenue, was one of these. He explained in detail and clearly some of the problems his unit meets and which previously have puzzled many mine men. He showed how the bureau slowly had built up a working system which at last is able to cope with the involutions of mine taxation and said that by 1923 the government will have cleaned up all of the excess profits tax cases. Mr. Kriegh said this would release approximately $200,000,000 capital now tied up. This release, he declared, would prove a great boon to the mining industry. The second government tax official present was Albert H. Fay, chief of the natural resources division of the Bureau of Internal Revenue.

Mining Classified as a Going Business

Carmi Thompson, of Cleveland, an iron-ore operator, who is candidate for Governor of Ohio, paid high tribute to Mr. Fay.

"Mr. Fay does all that a good man in his position can," said Mr. Thompson, "but he is handicapped by an unfair law—a law that is unfair because it classifies mining as a going business when it really is a liquidating one. The more successful the mining operation, the faster it liquidates."

At the Monday taxation conference, which opened the tax program at the convention, reports on various state tax methods were read and discussed. The central unit of the congress' tax committee reported its inability to recommend any uniform system of mine taxation for the whole country because of the wide variations of method now in use by states. But it suggested that a uniform general system be worked out to include the taxation of mines. The tax interweaving of mining and other properties is such that separation is out of the question. The committee declared that the immediate need of tax remedy is great, remarking incidentally that there is much underestimating of the amount of taxes paid by mines, and that the industry suffers by reason of such estimates. It suggested that while it is difficult now to combat such errors made in defence of high mine tax rates, a library of tax information such as the congress contemplates creating should end this embarrassment.

Hammering home the idea that the present rather chaotic condition of mine-tax matters is expensive to the industry, an estimate was made that the 18,000 mining companies of the country paid out more than $2,000,000 to prepare and make their income and capital stock tax returns in 1921 and that adjustments cost the companies a total of approximately $23,000,000 more, bringing the total cost to at least $25,000,000 for that one year. The remaining sessions of the conference were intended to bring out possible remedies for the tax situation, so that this cost could be reduced.

Paul Armitage, of New York, who presided at most of the tax conferences, on Tuesday read an exhaustive paper on "Distributions from the Depletion Reserve Under the Federal Tax Laws," elucidating the laws on the subject passed since 1913 and now controlling. He remarked that there still is some doubt as to whether a quota of the capital invested in mines must be debited against annual profits to calculate net profits, but that this is not vital because since 1916 the government income tax laws make complete allowance for depletion. There is so much difference of opinion, however, over methods to be used in arriving at the proper annual allowance for depletion that Mr. Armitage suggested a committee of the Mining Congress take up the question with the U. S. Commissioner of Internal Revenue and the Division of Natural Resources. R. V. Norris, a well-known mining engineer of Wilkes-Barre, Pa., presented a discussion on the valuation of mine properties.

Progress in Mine Accounting Methods

At the same session T. O. McGrath, of Bisbee, Ariz., a recognized authority on mine accounting, presented a progress report of his committee on mine accounting methods in relation to federal taxes, and W. R. Ingalls, of New York, addressed the conference on "Mine Taxation in Louisiana." Mr. McGrath's committee held that since the mining industry has never standardized its accounting and costing methods, it was only natural that the Treasury Department go ahead and crystallize its regulations whether the mine men agree with them or not; so the committee recommended that uniformity be arrived at within the industry. On Wednesday George E. Holmes, of New York City, author of "Holmes—Federal Taxes" and chairman of the congress' special committee on state taxation, spoke on "Invested Capital of Mining Corporations." Robert N. Miller, a former solicitor of internal revenue for the Treasury Department, explained a series of special and significant cases under recent revenue acts and Mr. Kriegh, of the congress' tax division, clarified many points on proper procedure in effecting settlements and compromises with the Commissioner of Internal Revenue.

The following resolution on state taxation was introduced by the tax conference:

Resolved that the report of the special committee on state taxation be accepted as read at this conference and that the thanks of the American Mining Congress be extended to the members of said committee and to those who co-operated with them.

Further resolved that since it seems impossible to obtain uniformity in mine taxation until such time as the various states agree to uniformity in the principles of general property taxation, the subject of improvement in methods of local taxation of mines be referred to the tax committees of the several chapters of the American Mining Congress.

Further resolved that subjects of general interest in mine taxation be referred to the standing tax committee, with power to confer with and aid the tax committees of the several chapters; and

Be it further resolved that a general tax committee be created to be composed of one member from each state, to co-operate with the standing tax committee of the American Mining Congress on all matters of general interest in taxation. The members and officers of the standing tax committee of the national organization shall be ex-officio members and officers of such general committee; and

Resolved that the Board of Governors of the several divisions appoint at this session, or as soon thereafter as practicable, from each state within their jurisdiction, one man to be a member of such general tax committee, and that where a state is beyond the jurisdiction of the Board of Governors the standing tax committee be authorized to select from each of such states one man to act on such general committee.

Problems of Operating Men

Edited by James T. Beard

Regarding the Use of Booster Fans in Mines

Instances Where the Use of Booster Fans Becomes a Necessity—Other Cases the Result of Bad Management —Need of an Efficient Mine Superintendent or Manager

FROM time to time there have appeared, in *Coal Age*, numerous references to the use of booster fans for conveying the ventilation in certain mines. In offering the following remarks, it is not my desire to refute the claims that have been advanced as to the advantage gained by the installation of such a fan in any particular mine.

Undoubtedly, there are instances where it becomes necessary to set up a small blower or booster, in a portion of a mine that is about to be abandoned, and where it is impracticable to incur any unnecessary expense to improve the ventilation in that section. But, the air being bad, it is realized that something must be done to improve the condition where the men must work for a time longer.

While this is true in a few cases, it appears there are many instances where booster fans have been installed as a supplementary unit, in providing the required circulation of air in the mine. My observation and experience warrants me in saying that all such cases are solely the result of bad management.

Proper Plan and Management Will Obviate Need of Boosters

In my opinion, if a mine is properly laid out and its air-courses and passageways ordered, cleaned and kept free of all obstructions to the flow of air, no occasion will arise calling for the installation of a booster fan in order to maintain the required amount of air in the working places.

Whenever a booster is found up at some point back of a mine, it is safe to say that the possibilities are there of some foul atmosphere. The mine may be an old operation that has been around for fifteen or twenty years and has been in charge of, perhaps, two or twelve different foremen, many of whom have taken little interest in keeping up the mine with an eye to its future development.

Some of these foremen may not have anticipated staying in the place longer than to give them an opportunity to secure a position elsewhere. In every case, it is easy to imagine that the mine would be allowed to get into bad shape in a short time, because nothing is done to prevent it.

The chief desire of a temporary foreman of this kind is to keep a low cost-sheet and put out cheap coal. In order to do that, he allows dirt to accumulate on the roads; falls of roof in the air-courses go unheeded; timbering of entries is neglected and complaints of bad air in the working places are frequent.

Under these conditions, there is sure to be evidence of bad management everywhere throughout the mine. This will continue until affairs take a turn and the officials wake up to the idea that a change of foremen is necessary. It is wholly to the advantage of a coal company to employ an efficient and reliable foreman—one whom they can retain in permanent charge of the mine.

Business Foremen Needed

If a business man of intelligence and experience is needed in any position in a coal operation, it is in the position of mine foreman. Personally, I have seen much money wasted through careless and indifferent management on the part of the foreman in charge. For one reason or another, foremen are often prone to retain more men than they require and, yet, the mine is not kept in the best working condition.

No foreman is efficient unless he keeps the mine in his charge in good working condition at all times and plans the work with a view to the future development of the property. As the workings of a mine are extended, the foreman must be able to provide separate air splits that will insure good ventilation at the working faces. To do this, he must have a thorough knowledge of the theory and practice of ventilation.

Inefficiency Quickly Shown

As may be inferred from my previous remarks, inefficiency on the part of a foreman in charge of a mine will show itself quickly through the bad results obtained in its operation. This may not appear in a day, or a month. In some cases, it may require a year or more to prove the inefficiency of a mine foreman, unless the management are keen observers and have a thorough knowledge of the practical operation of the mine, and the needs of its future development.

The shrinkage of output and the daily mounting of the cost-sheet are, of course, warnings of breakers ahead; but, often, present fears are allayed by the plausible excuses of the mine foreman. It is then up to the management to form their own independent opinions, and determine whether the fault lies with the foreman, or that the condition is unavoidable.

In closing, let me say that dirty tracks, falls of roof blocking the air-courses, accumulation of water at the working faces, or on the main haulage roads, cannot be explained away by excuses, provided the foreman has the means at hand for doing the work required.

O. Kennett,
Mine Foreman.

Hillside, Ky.

Relation of Foremen and Miners

Need of training all miners to have confidence in themselves—Two types of mine foremen—Two types of miners.

READING the article "Gaining the Confidence of Men," by G. W. Breeden, *Coal Age*, Aug. 24, p. 290, it occurred to me that it would be a good idea to inspire our miners to have more confidence in themselves, and rely more on their own judgment in the placing of their shots and the standing of their timbers. Teach them to take proper care of their working places, and not to depend on the foreman to tell them how and when to do these things.

In my opinion, it is a good thing for a miner to confer with his boss when he visits his place, and ask for his ideas in regard to standing timbers under dangerous top. But a miner should never wait for him to point out where timbers should be stood to make the place safe.

Train Miners to Independence

Miners should be trained to be careful and watch for any dangerous conditions that may appear. Then, without waiting for the boss to tell them what to do, the man should proceed at once to make himself safe.

It seems to me that the efficiency of miners who stand timbers only when and where the foreman says, or depend on him to arrange their shots, cannot be estimated very highly. It is all right for a miner to have the utmost confidence in his foreman's judgment, in regard to standing timbers and arranging and charging shots; but every miner should be trained to take care of himself without being told to do so.

The foreman should be a man of experience, whose judgment can be re-

lied on in almost any emergency arising in connection with the mine work; but that does not signify that he should know where timbers are needed in a working place any better than the old experienced miner who works there every day.

Training a miner to depend on his foreman to tell him what things he must do to keep his place safe has a tendency to cause him to loose confidence in himself in that respect. A miner who has no confidence in his own ability to stand timbers and arrange his shots in working his place is worthless as a mine worker.

Type of Foreman on Whom Miners Learn to Depend

Competency and ability on the part of the foreman to fill the position he holds and honesty in dealings with his men will gain their abiding confidence. Consider two foremen, for example: Of one it can be said, he is a kind and pleasant fellow; but he does not know anything about practical mining. Can you rely on his judgment, or on anything he may say regarding the work? He is ready to make promises, and just as ready to forget them. Such a foreman cannot gain or long retain the confidence of his men.

Of the other foreman it can be said, he is rather an unsocial man, or distant in his manner; but when it comes to business you can rely on what he says. His word is as good as his bond. He talks but little, but means all he says. His judgment about the work is good; and he gives it when and where it is needed. Miners will have confidence in such a foreman, though he may be close and strict in his dealings with them—friendly but never intimate.

Two Types of Miners Compared

In a certain coal mine, there are two miners employed. One of these is not skilled in his profession, although he has been in the mines for years. He is incompetent to do work where care and the exercise of good judgment are required. The other miner has not been in the mines many years, and yet he is skilled and competent to do any kind of work pertaining to the mine. He is a good workman.

If in a section of this mine there is a dangerous and difficult piece of timbering to be done, which of these men will the foreman choose for the work? Will he select the miner first named? Can he have confidence in his judgment and ability to perform such work? The answer is, No!

Some miners profess great friendship and respect for their foreman as long as they are shown special favors; but when there are no favors coming, their regard for him wanes. The better element of miners, however, have confidence in the foreman who is honest and capable; and who, in a business way, looks after the welfare, interest and safety of all and treats all his men with equal fairness in his dealings. A foreman who sacrifices honor and principle to gain the favor and confidence of a few of his men will soon lose the respect and confidence of the better and more intelligent element.

Practice of the Golden Rule the Key to Mutual Confidence

In the article previously mentioned, Mr. Breeden says in substance that his experience as mine foreman has taught him to treat his men as he would have them treat him under similar circumstances. Let me add, the practice of that principle is the key that will unlock the door to a mutual and abiding confidence between men and officials. The hope of industrial peace is to be found in the practice of the Golden Rule.

Former State Mine Inspector.
Dayton, Tenn.

Longwall Retreating in the Panel System

Butt headings driven up the pitch—Panels worked out by the retreating method of mining.

REFERRING to my previous letter, describing a method of handling a fire situation in a longwall mine, *Coal Age*, Aug. 17, p. 248, it appears I did not make myself clear in regard to the method of working out the panel.

Starting on the main headings, each panel is worked by driving three pairs of butt headings directly up the pitch. Each pair of headings was driven on 50-ft. centers, leaving 245 ft. of solid coal on each side of each pair of butts. It is stated that these pillars were to be worked out on the longwall retreating system. In my opinion, the area within the panel could not be worked on the retreating system, until other developments had been driven to the outer edge of the panel area.

My idea was to drive longwall advancing faces across the pitch, starting left and right from the butt entries and leaving the necessary gateways for switches, at suitable intervals, on each pair of butts.

Thomas Allen.
Mine Rescue Station,
Mt. Harris, Colo.

[It is difficult to understand how working out a panel, by extending a longwall advancing face across the pitch, to the right and left of each pair of butt headings within the panel, would eliminate the danger of fire due to heating of gob areas. It was not so stated in the description given by this correspondent, in his previous letter.

The purpose and aim of the previous letter was, evidently, as there stated, to overcome the danger of the heating of the gob by reason of the mixture of the fine coal, slack and clay cuttings formed in mining the coal. It should be apparent that there is more danger in employing the advancing system of longwall, in working out the panel, than by driving the butt headings up to the barrier pillar, at the top of the panel, and then working back the pillars on the retreating system.

By the retreating method, it is clear there are no gob areas to be left between the working face and the gangway, as in the advancing system. The retreating method of working out the panel wholly eliminates this condition and overcomes the danger due to the heating of the gob, which was understood to be the plan suggested by this correspondent.—Editor.]

Firing Shots from Surface After Men Have Left Mine

System of long standing still in use—All shots fired from the surface by electricity—Current taken from the generator in the power house.

IT WAS with much interest and pleasure that I read the recent reference to the custom of firing all shots from the surface after the men have left the mine, which has been in use at the Dawson mine, on the Stag Canon Branch, of the Phelps Dodge Corporation.

Permit me to say that this system, which has been in vogue for a long time at this mine, is still in use alhougth the firing, now, is not done by battery; but the current is taken from the generator in the power house. As the mine was extended, this change was found to be necessary, in order to provide a stronger current than could be obtained from the hand battery first used. Notice of the continued use of this system at this time I thought would be of interest to readers. The fact of the practice being of long standing is evidence in itself of the satisfaction it has given.

Chief Advantage Gained by Firing Shots From the Surface

It is unnecessary to refer to the chief advantage derived by the adoption of this method of firing shots in the mine, by which all accidents to men and to shotfirers are eliminated. As has been stated, the use of permissible explosives, in place of black powder, practically eliminates the danger of fire being started by the shooting.

However, as a further precaution, fire runners should enter and examine the mine to see that no such danger exists, shortly after the shots have been fired. Time must be given, only, for the air current to sweep away the gases produced by the shots.

W. F. Murray,
Dawson, N. M. Safety Engineer.

Charging Holes With Steel-Headed Tamping Bars

Steel tamping bars dangerous under any conditions—Danger greatly increased if coal contains sulphur—Charging a hole with loose powder a dangerous practice—Tamp all holes with clay

READING a recent reference to the blasting of coal in mines, in respect to the dangers attending that work, I am reminded of one or two dangerous practices to which, I believe, attention has not as yet been drawn.

The first point I would mention, in this connection, is the use of steel-headed tamping bars. In spite of all

that has been said, the practice has grown to a considerable extent in this district. It would seem that, for their own safety, miners would discontinue the use of such bars and employ wooden ones instead.

In our mines the coal contains much sulphur, both in the form of sulphur balls and streaks of sulphur. This makes the use of steel bars for tamping shots all the more dangerous and should be a warning to mine officials and miners that such bars should be discarded.

Drilling a Sulphur Ball

When a miner, in drilling a hole, strikes a sulphur ball he makes every effort to pass the obstruction, if possible. At times, this results in deflecting the drill and produces a slight curve in the hole; but, in any event, the sulphur ball remains exposed at the side of the hole.

Now, if such a hole is tamped with a steel bar or a bar with a steel head, there is every chance of a spark being struck when the bar comes in contact with the sulphur ball. The probable result is an explosion of the charge in the hole and the injury or death of the miner. Such accidents are common in our mines, although they are wholly avoidable if proper precautions are taken and steel tamping bars prohibited.

Again, this coal contains many small streaks of sulphur so that the auger is drilling in sulphur, more or less, the full length of the hole. For that reason, the danger of striking a spark when tamping the hole with a steel bar is all the greater.

Drilling with a Worn Bit

Incidentally, let me refer here to the increased danger when a miner resorts to another dangerous practice. It often happens that his auger has become so worn that the diameter of the hole is too small to allow the cartridge to be pushed safely to the bottom of the hole.

In that event, what does the miner do? Nine out of ten, perhaps ninety-nine out of a hundred, will open the cartridge and proceed to pour it as best one can into the hole, at the same time pushing it back to the bottom of the hole with the tamping bar. Then, it is a miracle if the man escapes the terrible results of the chances he is taking.

Now considering these dangers, so common in blasting coal, every mining man will agree that the charging of a hole with loose powder and the use of a steel-headed tamping bar should be absolutely prohibited by the mine rules and regulations, regardless of whether the same are forbidden by the mining laws of the state.

Allow me to suggest that every coal operator should keep on hand, in their supply houses, tamping bars with copper or babbitt heads and sell the same to those miners who are not previously equipped with such bars. It should be an invariable rule that no miner will be permitted to use another kind of bar, excepting it be a wooden one.

In my opinion, it should be the duty of the district mine inspector, in making his rounds of the working places when inspecting a mine, to see that the miner is supplied with a suitable tamping bar. He should urge that these be kept on hand in the supply house, and sold to any miner who is not already supplied. The bars should be sold to the miner at cost, with freight charges added.

In the same connection, let me suggest that coal companies should supply their miners with clay or other incombustible material for tamping their shots. This will go far to obviate the use of fine coal dust and slack for that purpose, which is too often the practice of miners where other material is not at hand.

It is hardly necessary to repeat what has been so often urged in *Coal Age*, that competent shotfirers should be employed whose duties it would be to examine, charge and fire all shots in the mine, except such shots as are, in their judgment, for any reason unsafe.

Every miner should be instructed to remove the fine coal cuttings, after drilling a hole in his place. In most cases, arrangements should be made for taking these cuttings out of the mine. Where dustproof cars are in use, the cuttings can be loaded out with the coal.

In closing, let me say that when these and a few other precautions necessary for safety are followed by miners and the officials in charge of the mine, we shall see a gradually decreasing percentage of mine accidents. What is needed is the strict enforcement of rules for safety.

OSCAR H. JONES,
Wilder, Tenn. Fentress Coal Co.

Inquiries Of General Interest

When To Install a Booster Fan

Conditions That Make It Advisable to Install a Booster in a Mine—Such a Fan Only to Be Regarded As a Makeshift —Dangers Incident to the Installation of a Booster Fan

KINDLY permit me to ask, through the columns of *Coal Age*, for a little information regarding the installation of booster fans in mines. I am desirous of learning the advantages and disadvantages of installing such a fan.

Owing to the increasing difficulty of ventilating the workings in our mine, we have had before us the proposition of installing a booster fan at some advantageous point in the mine. The seam of coal we are working has an inclination equal to a grade of 25 per cent. The slope has reached a depth of 6,000 ft. The coal is being worked out on the room-and-pillar system.

If it is practicable to install a booster fan, I would like to know at what point in the mine it should be placed. Also, how can I ascertain if the return airway is of sufficient size to carry the increased volume of air desired. It is important to know this before attempting to make the installation.

MINE MANAGER.
Kemmerer, Wyoming.

It is strange that this question, regarding the advisability of installing a booster fan in a mine, is so often asked when there is but one answer to be given. The installation of a booster fan should never be considered by a mine management if it is to be operated as a unit of the ventilating system. It should be understood that the office of a booster, in any event, is only intermediary. It cannot act to materially increase the circulation throughout a mine. Its effect is only local, the fan acting to draw the air from the main current and send it coursing through a section of the mine where the ventilation is slack owing to leakage of stoppings back on the road.

There are conditions that arise from time to time, however, when the ventilation has become poor, in a section of a mine that is nearing completion and about to be abandoned. In order to improve the circulation in this portion of the mine it would be necessary to go to considerable expense in the repairing of old leaky stoppings. To avoid this expense and yet improve the circulation of air in the section, recourse is often had to the installation of a booster fan and this is placed near the mouth of the intake airway, in that section.

The great disadvantage of making this installation is the constant watch and care required to see that the fan is kept running. A booster is commonly operated by a small electric motor, which is dependent on the power supplied to it through a conductor. A fall of roof breaking the wire will put the fan out of commission; or any neglect on the part of the attendant whose duty it is to look after the fan will have its effect to reduce the circulation in the section it is supposed to ventilate.

The trouble may occur after the fireboss has examined the section and before the men enter for work, with the result that gas may have accumulated

in dangerous quantities in the working faces. Therefore, at the best, a booster fan should only be regarded as a makeshift, for the purpose of avoiding expensive repairs in a portion of the mine that is about finished.

It is unnecessary to dwell further on the dangers that follow in the wake of installing a booster fan at any important point in the mine. In case of an explosion in the mine, such a fan is of little or no assistance to the rescuers who would enter the mine. The sparking of the motor is an added danger, in a mine generating gas. It is a safe general rule never to place any ventilating apparatus at any other point than on the surface where it will be subject to constant supervision and accessible at all times.

Examination Questions Answered

Indiana Mine Bosses' Examination, Indianapolis, 1922

(*Selected Questions*)

QUESTION—*Give five causes of accidents that occur on haulageways, and state the method to prevent them.*

ANSWER—1. Accidents to persons walking the road and being caught by a car or trip. 2. Accidents due to men and boys riding on loaded trips, contrary to the regulations of the mine. 3. Accidents to motormen and trip-riders when cars are derailed, causing a wreck. 4. Accidents due to cars standing on a room switch where the track is supposed to be clear for the motorman. 5. Collision of cars by reason of faulty schedules, or disobedience of orders by motormen and drivers.

To prevent these accidents from occurring: 1. Provide ample clearing space on one side of the track and refuge holes at short distances apart, kept whitewashed and free from all obstructions. Every trip should have a warning gong or other means of telling the approach of danger. 2. Enforce strict regulations in regard to persons riding loaded trips, and provide suitable penalties for violation of the rules. 3. Keep all haulage roads, tracks and switches in good condition, and establish a maximum speed for motormen hauling cars and trips. 4. Allow no cars to be left standing at the mouths of rooms, unless they are securely blocked to prevent their running out onto the main road. 5. Have a good schedule for the running of cars or trips and enforce strict regulations regarding the maximum speed of hauling.

QUESTION—*Give five safety precautions that a miner should observe on going to his working place at the face.*

ANSWER—1. A miner should enter his place with caution, observing carefully the condition of the roof and timbers as he proceeds. 2. If he has brought his powder with him, on coming into the mine, he must first put it in a safe place before proceeding. 3. He should look for the mark left by the fireboss, showing that the place has been examined and found safe. 4. Unless the mine is known to be free from gas, every miner should make a test to ascertain that no gas is present at the roof or in cavities where it might lodge. 5. Before starting to load his coal, the miner must set any timbers that may have been discharged by shots the night before.

QUESTION—(*a*) *What is the law respecting air measurement in the mine?* (*b*) *What advantage is such a measurement?*

ANSWER—(a) The Indiana Mine Law (Chap. 258, Sec. 11) requires the mine boss to measure the air current, at least once a week, at the inlet and outlet of the mine and at or near the face of all entries; and keep a record of such measurements in a book provided for that purpose, said book to be open for the inspection of the inspector of mines. He must also, on or about the first day of each month, mail to the inspector a true copy of the air measurements taken, stating the number of persons employed, the number of mules and horses, and number of days worked in each month. Separate air splits must be provided for each fifty persons at work in the mine; and the law authorizes the inspector to require a separate air split for a less number of persons if, in his judgment, conditions make it necessary; and to require that any desired changes for the improvement of the ventilation be made within a reasonable time; or he may withdraw the men if this is not done.

The law has the advantage that the measurements taken at the points designated show how much of the air current reaches the working faces; and, by limiting the number of men working on a single air split, the law provides a safeguard against too high a velocity of the air sweeping the working faces.

QUESTION—*What are the causes of dust explosions in a mine, and what is the best known method to prevent them?*

ANSWER—The chief causes of dust explosions are: The excessive use of powder in blasting the coal; failure to remove the fine cuttings in machine mining; neglect to clean up roads and air-courses and remove accumulations of dust in the working places. To prevent these occurrences, permissible powder should be used and the blasting performed by competent shotfirers. No accumulations of dust should be permitted at the working faces throughout the mine. Roadways and air-courses should be cleaned, at regular short intervals, and an effective spraying system installed in dusty mines where the coal is highly inflammable.

QUESTION—*In what way would you provide for the protection of your men from falling roof?*

ANSWER—Frequent careful inspection of the working places, by the foreman, assistant foreman, safety inspectors and firebosses; and the enforcement of strict rules and regulations regarding the setting of timber in working places, will go far toward protecting the men from roof falls at the working face. Particular attention must be given to the work of drawing pillars. All workers must be carefully instructed in respect to making themselves safe. In addition, an ample supply of suitable timber must be kept in all working places, ready to use when needed. The most effective safety device known, however, is a careful man.

QUESTION—*What is the best and safest way to detect the condition of the roof?*

ANSWER—Besides the usual method of sounding the roof with a pick, holding one hand against the roof while striking the blow, to detect any tremor or hollow sound that would indicate an unsafe condition, it is important to make thorough inspection to see if any slips or fault lines are present. If these are found they must be carefully studied and means taken to avoid accidents therefrom.

QUESTION—*What is the danger arising from working a mine adjoining an abandoned mine?*

ANSWER—The abandoned workings may contain accumulations of water or gas that would flood the live workings and endanger the men should a place break into the old works. In order to minimize this danger drillholes must be kept in advance of the faces of all places approaching old workings that have been abandoned. No reliance should be placed on the accuracy of surveys of such mines.

QUESTION—*Give method of procedure in case an explosion occurred in a mine of which you had charge, and the ventilating devices have been injured and men must be rescued.*

ANSWER—Call for volunteers and select the most experienced men to form rescue parties. Make such temporary repairs as are necessary to restore the ventilating current. The rescuers, equipped with safety lamps and wearing breathing apparatus, if such is available, must enter the mine with the air and proceed with caution, making only such repairs as may be necessary to restore the current. Send at once for physicians and other assistants.

British Household Coal Prices Now 63 Per Cent Higher Than Before War

[illegible] household coal prices of those qualities of coal most largely used by the bulk of householders in Great Britain is considerably less than one-half of the total, as shown in the following table:

The distribution charge includes trades' and rate notes' wages, lorries expenses, carts, riding costs, salaries and establishment charges and profits.

Doubt Brights are sold at an additional shilling per ton, the pit-head price being a shilling more than that of the fuel previously mentioned. In 1913 the pit-head price of this fuel was 11s., railway rate and wagon hire amounted to 7s. 4d., and distribution charges 6s. 8d., the total making 25s. The present price is thus about 63 per cent above pre-war quotations.

Kentuckians to Consider Mine Problems

Under the leadership of A. G. Spillman, general superintendent of the St. Bernard Mining Co., Earlington, Ky., their president, the Kentucky Mining Institute will assemble, Nov. 3 and 4, at the Seelbach Hotel, Louisville, Ky., to discuss mining problems with special reference to the needs of their industry at the mines of their state.

Two committees will report, one on the preparation of coal and the other on coal mining machinery, the latter being presented on behalf of the committee by Alphonse F. Bruley, [illegible] editor of *Coal Age*. This will occupy the first session, opening at 10:30 a.m. The second session, at 1:30 p.m. of the same day, will hear papers, one by Graham Bright, chief general engineer of the Westinghouse Electric & Manufacturing Co., of Pittsburgh, Pa., on "Gathering Locomotives for Coal Mines;" another by C. D. Franks, district engineer of the Portland Cement Association, on "What Good Roads Mean to Mining Districts," and a third by J. M. Dewberry, general coal and coke agent of the Louisville & Nashville R.R., Louisville, Ky., on "Present Coal Traffic Problems and Prospects for the Future."

The same evening at 8 o'clock a smoker will be held at which the subject to be discussed will be: "How to Make an Operators' Association of Most Value." In this discussion the following are scheduled to discuss the problem: R. A. Hunt, secretary, Bazard Coal Operators' Exchange, Lexington, Ky.; R. E. Clayton, secretary, Harlan County Coal Operators' Association, Harlan, Ky.; J. E. McCoy, secretary, Southern Appalachian Coal Operators' Association, Knoxville, Tenn.; J. E. Butler, general manager, Stearns Coal & Lumber Co., Stearns, Ky.; C. F. Richardson, president, West Kentucky Coal Co., Sturgis, Ky.; R. C. Tway, president, R. C. Tway Coal Co., Louisville, Ky.; Munro B. Lanier, president, Munro-Warriner Coal & Coke Co., Birmingham, Ala.; C. S. Nield, general manager, Pioneer Coal Co., Kettle Island, Bell County, Ky.; K. A. Mequire, president, the Harlan Coal Co., Louisville, Ky.; Harry E. Bullock, president, Carrs Fork Coal Co., Lexington, Ky.; Frank D. Rash, president, St. Bernard Mining Co., Earlington, Ky.; F. P. Wright, general manager, Crescent Coal Co., Bevier, Ky.; James D. Overall, general manager, Reinecke Coal Mining Co., Madisonville, Ky.; C. J. Norwood, University of Kentucky, Lexington, Ky., R. Dawson Hall, Engineering Editor, *Coal Age*, New York City.

On Saturday a business session will be held at 9 p.m., after which the meeting will be adjourned.

Cliftonville Case Involves 218 Union Men 71 Charged with Murder

Two hundred and eighteen union miners were placed on trial at Wellsburg, county seat of Brooke County, W. Va., on Oct. 9, charged with complicity in the death of Sheriff H. H. Duvall, of Brooke County, who was killed while repelling an attack on the Cliftonville mine of the Richland Coal Co., on July 17. Seventy-one of the defendants are charged with first-degree murder. The indictments range from murder to conspiracy, burning of property and assault. As many as half a dozen indictments are pending against some of the defendants, all of whom, it has been announced, will be prosecuted to the full extent of the law.

Prosecuting Attorney W. S. Wilkins of Brooke County will be assisted by John J. Coniff and J. B. Handlan, of Wheeling. Charles J. Shuck resigned as Assistant District Attorney to engage in the case as counsel for the defendants, and has associated with him D. A. McKee, formerly prosecuting Attorney of Ohio County; F. A. O'Brien and M. J. Cullinan, all of Wheeling, and John D. Gardner, of Steubenville, who was once a miner. One of the most interesting phases of the case is that John J. Coniff, who was the principal attorney for the defendants in the Matewan case, will act as one of the principal attorneys for the state in the Cliftonville case.

Martial Law Lifted in Mingo County

Martial law, established in Mingo County, West Virgina, June 27, 1921, more than fifteen months ago, after a series of outbreaks, which resulted in several deaths and the destruction of considerable property, was raised Oct. 7 by Governor Morgan. Peace has been restored along the Tug River, where war between union and non-union miners spread terror and resulted in the intervention of federal troops.

New England in Fair Way To Escape Domestic Coal Shortage

Warm Weather, Cellar Stocks and Plenitude of Substitutes Reassure—Massachusetts Takes Steps to Safeguard Supply—Goodly Share of Anthracite Shipments Goes Down East

New England has made strenuous efforts to avert a domestic coal shortage before the advent of coal-burning weather. Despite all the warnings of an impending famine, there are several encouraging factors in the situation in that section which indicate that household consumers may "get by" with a minimum of inconvenience this winter.

Unseasonably warm weather has delayed the lighting of furnaces. This has proved a welcome respite to retail dealers and has enabled shippers to spread a thin veil of anthracite over the territory as a bulwark against the insistent demands which will come with the first cold snap. More coal went into cellars just prior to the anthracite suspension than has been generally realized. New England got a fair proportion, at least, of the mine storage stocks that were moved during April, May and June. Substitute fuel is plentiful; little has been distributed at retail, but it will be available when wanted. Lastly, economy in fuel consumption can always be expected during a period of shortage with its attendant high prices.

Conditions in Massachusetts are typical of New England as a whole. That state, through its Fuel Committee, is taking active steps to safeguard the fuel supply and protect its citizens from extortion. In urging upon the Federal Fuel Distributor, at Washington, the necessity for adequate supply and reasonable prices, James J. Phelan, Massachusetts Emergency Fuel Distributor, describes the situation in that state as follows:

UNLOADING BRITISH STEAMER AT MYSTIC WHARF, BOSTON

During fuel emergency New England railroads and industries have been heavy takers of British coal, straining unloading facilities and congesting our harbors with boats awaiting their turn at the wharves.

"Bituminous reserve stocks for industrial purposes are not in excess of the line of safety, considering our remoteness from the mines. Anthracite deliveries by dealers to householders so far this season, commencing April 1, are carefully estimated not to have exceeded 25 per cent of the total quantity customarily distributed by dealers to householders within the same period of time in normal years.

"In view of the fact that the people of New England and of Massachusetts have always used anthracite for their household needs, and we have this year lost five out of twelve months' anthracite production, it follows that our people will be unable to secure adequate anthracite supplies. We shall, therefore, be compelled to use considerable substitute fuel to take the place of, or mix with, such supplies as we may be able to secure.

Would Not Hesitate to Issue Embargoes

"I am glad to observe that you are exerting every effort to secure the fullest transportation services in order to provide the maximum quantities available as promptly as possible. I, therefore, trust that you will not hesitate, whenever the occasion requires, to issue embargoes, and establish priorities that shall maintain constant and equitable distribution between states. In this connection may I point out that in my order of Sept. 21 'all dealers and consumers receiving fuel in carload lots must unload such cars within the twenty-four hours following the receipt thereof. Every day saved in the use of coal cars should be a gain of several tons in production.

"There exists to-day a variation of approximately $4 a net ton in the mine prices being charged Massachusetts retail dealers above the costs prevailing last March for anthracite, resulting in increased costs to our householders. I can, and shall, control the gross margin which may be added by dealers to the cost of coal to them, in order to prevent extortion within the state, but it is obvious that the cost of coal at its sources is beyond my control. You will understand that our earnestness in this matter is based upon our desire that the federal and state governments shall fully co-operate in such a way as will secure to the citizens of Massachusetts the best results possible under the present difficult conditions."

New England is getting more than its fair share of current anthracite shipments, when the meager Western and Lake movements are considered. Requirements for the winter in Massachusetts are estimated at [illegible] tons. By Oct. 1 all-rail shipments of anthracite in this section were averaging 300 cars per day. The normal movement is 425 cars. If this movement and shipments by water can be maintained the estimated shortage of 1,000,000 tons will be reduced materially. However, this shortage will occur for the most part at the beginning of the season, therefore the main problem is to overcome this difficulty for perhaps 60 or 90 days, after which it is expected that the conditions will gradually become normal before the winter has ended.

Note—The headline shows a Black Hand "sentiment" seen near Providence.

BRITISH CARGO ON SCOTIC RIVER
[illegible] awaiting [illegible]

Consumers are not buying our bituminous coal as a substitute for anthracite. The high freight rates make that most prohibitive except as a last resort. The householder feels that this coal can be obtained in a pinch, but he will not buy it unless the pinch comes. A drive has been made on the domestic market by British sellers, in an endeavor to place some of their coal. Shippers offered "Welsh semi-anthracite" along the Eastern seaboard at prices that compared favorably with our own hard coal. Some few cargoes have moved in, but the amount distributed by retailers has been insignificant and little additional tonnage is now expected. New England railroads have been heavy takers of British commercial fuel. Many cargoes are in the harbors and others are still coming. This unusual flow of coal has been transported in a miscellaneous assortment of bottoms, many of them of a type that has caused delay at New England unloading machines. But despite much congestion the price has been kept at a level which still attracts the New England railroads, which are taking advantage of this opportunity to add to their reserves.

British Fuels, Though High Grade, Do Not Ship Well

British shippers also made an attempt to push their Admiralty Large for domestic purposes, but, like the Welsh semi-anthracite, this coal has not cut much of a figure in the domestic market. Both are high-grade fuels, but do not ship well. The New Englander has been so accustomed to the use of our clean and uniformly sized anthracite that the physical appearance alone of the British coal has been against its sale at retail. The following analyses were made from recent receipts in New England:

	Welsh Semi-Anthracite	Admiralty Large
Carbon	82 75	78 79
Volatile	11 45	14 09
Ash	1 95	5 38
Moisture	1 05	77
Sulphur	88	97
B.t.u.		14,810

Coke is finding a better market for domestic purposes than for years past. The present emergency also has produced a strong market for Rhode Island coal, which is being sold not only at points adjacent to the mines but is finding its way to more remote New England points. The public had lost much of its faith in this coal, partly because of its weight, which made it appear small in bulk when delivered, and partly because of its excessive ash content, but mainly because of the difficulty in kindling it. This coal is extremely variable in character and quality, ranging from anthracite to graphite and, unlike Pennsylvania anthracite, its high content of water necessitates a special drying process. During the last year or so extensive experiments have been made in preparing and firing this fuel, and at the present time one company at least is putting it on the market in sizes and condition that makes it an excellent substitute for Pennsylvania anthracite and at a price which is attractive. New methods of firing are necessary; the coal needs considerably more draft than other fuels, but once one becomes acquainted with its peculiarities it is said to be far more satisfactory as a domestic fuel than bituminous coal.

Anthracite receipts are making inroads on the shortage with every day's delay of cold weather. With the practice

BOSTON & MAINE R.R. TAKES MUCH BRITISH COAL
Unloading cargo directly into railroad cars, shown in foreground.

of economy and a plenitude of substitutes at hand when wanted, the worst that New England householders should experience this winter is the necessity of adapting themselves to the use of unfamiliar fuels. At that the substitute tonnage will not be large and its use will be confined to the early part of the season.

AWAITING CARS TO TAKE BRITISH CARGO
[illegible]

The U. S. Bureau of Mines, in co-operation with the U. S. Public Health Service and the Society of Heating and Ventilating Engineers, is engaged in a study of the relative importance and correct correlation of the many individual factors concerned in the problem of the physiological effect of different conditions of temperature humidity and air motion. A special room has been constructed for this purpose at the Pittsburgh station in which the air conditions are controlled by apparatus outside the chamber and entirely separate from it. A comprehensive program, which includes a quantitative study of a considerable number of bodily functions, is being carried out. The work has not yet been completed, but enough has been done to demonstrate the importance of determining the physiological reaction to environment as a measurement of the harmful effect of heat and humidity, and to show that feelings of discomfort as a standard of measurement cannot be depended upon because there is a certain adaptation of the sense organs to an unchanging environment, and individuals differ in their sense reactions.

Smokeless Operators Will Sell Domestic Sizes at $6; Spens to Probe Anthracite Prices Over $9.25

Prepared sizes of smokeless coal for domestic use will not be sold at a price in excess of $6 a ton, an agreement to that effect having been reached by the Federal Fuel Distributor and operators representing 80 per cent of the smokeless production. Fuel Distributor Spens gave out the results of the conference in the following prepared statement:

"The Federal Fuel Distributor had a conference on Oct. 14 with coal operators in the 'smokeless field' of West Virginia relative to coal prices. This field comprises the Pocahontas district, the New River district, the Winding Gulf district and the Tug River district, and the estimated total coal production in these four districts is 36,000,000 tons per annum. The operators that were present at the conference represent approximately 80 per cent of the commercial production.

"The maximum price f.o.b. mines on prepared sizes for household use that was observed by the operators, through co-operation with federal and state authorities, prior to cessation of the miners' strike, and at a time when the car supply in the 'smokeless field' practically equalled the demand, was $5.13 per ton, including sales agency's commission. With the settlement of the miners' strike in union coal districts the operators in the 'smokeless field' found it necessary to advance the wages in their mines materially, resulting in an estimated increased cost of production of the prepared sizes of approximately $1 per ton. In addition, with the ending of the strike, the car supply commenced to diminish, due to distribution of equipment that naturally had resulted from a wider distribution of this 'non-union' coal, the immediate demand for cars from 'union' mines, and the retarded transportation incident to the railway strike, until today the car supply in the 'smokeless field' is appreciably below currrent requirements and quite below the supply available at the time the former price was established.

Smokeless Coal Now Much in Demand

"The demand for 'smokeless' coal is very great, and since the termination of the miners' strike, at which time this understanding as to prices was cancelled, f.o.b. prices at the mines on domestic coals have ranged as high as $8.75 per ton plus 8 per cent sales agency's commission, or a total of $9.45 per ton. These operators, however, in appreciation of the present emergency and in a desire to co-operate with the federal government in the accomplishment of its purposes, indicated a willingness not to exceed a maximum price f.o.b. mines of $6 per ton on the prepared sizes of coal for domestic use, this price also to include the sales agency's commission. Therefore, effective at once, this will be the maximum price f.o.b. mines that wholesalers, retailers or other purchasers of these coals will be asked to pay.

"While, as stated, the entire production of the 'smokeless field' was not represented at the conference, we have been assured that the action taken by the very large majority will undoubtedly be followed by the remaining interests."

Conferences on the matter of coal prices are being arranged by the Federal Fuel Distributor with representatives of mine operators from each of the sixteen coal-producing districts east of the Mississippi River. Fuel Distributor Spens is giving attention also to the price situation in certain coal-producing states where it is reported that coal is being sold within the state at a certain maximum figure agreed upon with the state authorities while it is being marketed outside the state at figures in excess of this maximum.

Lieutenant-Colonel C. B. Hatch, U. S. Marine Corps, retired, has been designated with the permission of the Navy Department to act as the representative of the Federal Fuel Distributor on the fair practices committee of Pennsylvania, an organization which functions as a part of the Pennsylvania Fuel Commission and which is giving its especial attention to matters affecting the price and distribution of anthracite. Lieutenant-Colonel Hatch's residence is in Philadelphia. He succeeds E. M. Durham, Jr., who is resuming his duties with the U. S. Railroad Administration. Arrangements have been made for a conference between the federal distributor and a special committee of the National Coal Association, of which J. C. Brydon, of Baltimore, is chairman, to be held in Washington, Oct. 18, for the purpose of discussing matters relating particularly to transportation conditions and car shortages.

The following statement summarizing developments in the anthracite price situation was issued Monday night by the Federal Fuel Distributor:

"Approximately 75 per cent of Pennsylvania's anthracite is produced by the larger, or so-called 'company' operators. The balance is produced by the so-called 'independent' operators. On the 75 per cent production a price of $8.50 per ton f.o.b. mines, established by Pennsylvania state authorities prior to the creation of this office, applies to a maximum, although on a goodly percentage of the production prices ranging from $8 to $8.35 per ton have voluntarily been observed. On the remaining 25 per cent production prices range from $9.25 to as high as $14.25 per ton f.o.b. mines.

"The fair practices committee of Pennsylvania was appointed several weeks ago to investigate cost of the 'independent' production and to determine fair f.o.b. mine prices. The Federal Fuel Distributor is represented on this committee.

"This committee commenced to function about Oct. 1, and since that time, pending a more thorough investigation and final conclusions, 'independent' operators, representing approximately 20 per cent of the total production, have signified a willingness to observe a maximum price of $9.25 per ton f.o.b. mines, the prices theretofore on this production having ranged in some instances to as high as $10.50 per ton.

"In order that the fair practices committee may concentrate its efforts on the remaining approximately 5 per cent, on which production prices are today ranging as high in some cases as $14.50 per ton f.o.b. mines, the Pennsylvania Fuel Commission and the Federal Fuel Distributor have agreed as a temporary expedient to defer investigation of these independent operators whose prices will not exceed $9.25 per ton f.o.b. mines. The Fair Practices Committee have been advised by the Pennsylvania Fuel Commission and the Federal Fuel Distributor that their findings as to fair prices that should obtain for the 5 per cent production should be completed by not later than Oct. 31."

Jobbers' Commission, Neal Rules, Must Not Bring Coal Price Above Mine Maximum

Jobbers' and brokers' commission charges on sales of coal to retailers and consumers must not raise fuel prices above maximum levels fixed for coal at the mine by the state, under a ruling by C. J. Neal, state fuel administrator of Ohio and approved Oct. 11 by Governor Harry L. Davis. Under this ruling the "fair prices" of $3.50 to $4.50 established in Ohio include the middleman's profit. Mr Neal's announcement reads:

"Effective Tuesday, Oct. 10, prices received by producers in Ohio for coal sold to jobbers, brokers or wholesalers for delivery within the state and the commissions of such jobbers, brokers or wholesalers must not exceed the list of maximum fair prices announced Oct. 1 and effective Oct. 10 until changes are announced in such prices."

Argument in the assigned car case will be reopened before the Interstate Commerce Commission on Nov. 15. The docket in the matter of mine rating and coal car distribution rules will be considered at the same time. Commissioner Aitchison will preside.

Maurer Foresees Repetition of This Year's Trouble Next April*

[illegible] such a thing as a fear of a coal shortage in the Central Competitive Field had almost been silenced. [illegible] the old interstate agreement was formed, and I want to say without any limitation that it was a success and served its purpose. True, in the years the price of mining declined; true, in that the years capital starved to invest in West Virginia, and while our West Virginia friends may charge us with a great many evils, the interstate agreement in the Central Competitive Field and the wages we paid developed and built up West Virginia.

Capital went where capital controlled, and in the Central Competitive Field capital did not control. And as wages increased in Ohio and Pennsylvania notwithstanding the fact that they were within twenty-four hours of the great markets, heavy wages and control of labor gradually built up and developed the great State of West Virginia and brought them scale into the markets.

The [illegible] blessing that the people of West Virginia have today is the fact that we have had an interstate agreement and a high wage scale in the State of Ohio and the Central Competitive Field. In 1898 and from that date on [illegible] both labor and the employers had respect for each other's contract. It was the most binding contract that was made in this country, and both sides took pride in the fact that the contract was carried out. But the interstate agreement has served its purpose. Since 1916 there has never been a contract made with the United Mine Workers of America in the Central Competitive Field. What is the great underlying cause of all the legislation and all the interference and all the evils that we have?

There are but two: The United Mine Workers and railroad transportation.

The United Mine Workers have asked for government control. There isn't any easier way that they can get the government to step in and take control of your property than by creating situations like they have created in the last three years.

I believe in the right of property. I believe the right of property is just as sacred as a man's life, but nevertheless the advanced theory today is that the right of property is subject to the public welfare and the public good, and that is the crowded situation today and the situation which you and I must recognize in the operation of our properties.

By some custom there is a God-given right to strike that is recognized by the politicians, but I don't believe it is recognized by law. Instead of regulating the operator and the coal miner, in the name of common sense, why don't they regulate the strike and remove the cause?

I believe in uniform wages. There is no industry in the world that needs uniform wages more than the coal industry. With every man making his own wage at every mine, you sell your coal, you don't sell your product, and I don't believe in that, but when you are working under a uniform scale of wages you have to sell your product and not your coal.

My opinion is that the first of next April will be a repetition of last April. My opinion is that by the first of next April those districts that regulate the price of their labor by the law of supply and demand will be able to meet market conditions by reducing their labor to meet the market conditions. You can't have Mr. Lewis shut down the mines of the Central Competitive Field on the first day of next April, or you will lose control of your properties. There is no middle course with the United Mine Workers. We, the operators, say that we won't deal with the national officials but we will deal with our own officials—that is non-union. Why, it was evident for the Pittsburgh district to make the statement on the last day of last April: "We are ready to deal with the United Mine Workers but we won't deal with the national officials."

In conclusion, there is just this I want to say: The great coal industry must recognize, irrespective of what some people think, that they have an obligation to the public; they must recognize that the public has some rights in their property and they cannot so operate them as to injure the general public. They cannot by strikes and suspension force situations by which there is a demand made for coal that will warrant a certain scale of wages, because it isn't fair to the public; and between now and the first day of April force the whole industry of the Central Competitive states to so shape itself that if it is unable to take care of its own affairs, it must get such assistance as will give it at least protection.

* Abstract of address of C. E. Sharpe, president Deep Run Coal Co., before the American Mining Congress, Cleveland, Ohio, Oct. 13, 1922.

Bradley Defends Policies of Non-Union Operators*

During the long depression of 1921, when coal was a drug on the market, when the coal industry was ready for the hands of the universal receiver, the great Southern district was producing 80 per cent of its maximum.

That illustrates a very important point. There must have been a reason for that, and what was that reason? It was the ability to adapt itself to changing economic conditions. You travel through those fields and you will find enormous collieries, tremendous operations, wonderful mining towns, adapted to the comfort and the convenience of the employee such as you will find in no union field, where the bitterness and distress of class hostility has been injected, so that the operator doesn't feel like giving that man a decent place to live.

There in the South, where we have this co-operative spirit, you will find the cheapest living, the cheapest rents, the cheapest store prices; you will find co-operation in reducing wages and in raising them. We know when we should pay our men more and we do it. We are not tied up by a contract, running through every conceivable up and down of economic depression and keeping the men from getting a decent wage in good times, and taking the work away from them in bad times.

We only wish that you had the same advantages.

When I think about it I feel that I simply can't express to you what it means to the operator who is on that basis with his labor. It is a partnership, and that is what it ought to be. It is a man-to-man relationship. There is no third party to come between telling the thrifty workingman that he is being cheated; no third party to come in and tell the honest, hand-saving son of toil: "Don't work so hard."

Why is it necessary to have an investigating commission for the coal industry when the coal industry has been investigated by a public committee every eighteen months for the last seven years? Why can't they take some of that sworn testimony and give it to a man like George Otis Smith and have him compile it and tell the story, with the affidavits to back it up? It wouldn't be enough of a smoke screen.

Now, this is what we are getting out of Washington. This coal labor problem—I feel very much about my coal business as I do about my garden. I have been fighting bugs and insects and plant diseases in that garden from early spring until late fall every year since I can remember. My bill for insecticide is more than almost the pleasure that I get out of the garden. And that is just exactly what I have been doing with my coal business. I have been fighting the pests, the diseases, the assailants, and in West Virginia, by God, we fight them with a rifle, and so would you. You wouldn't let a sneaking skunk steal up and put a stick of dynamite under your house, would you; blow your wife and children to Kingdom Come ahead of you? I won't. I am for the gunman, the mine guard and every form of protection that I can get, as long as my government won't protect me! Let's have it out! That is what we are getting out of Washington.

Now we come to the crux of the labor problem. It is a question of the enforcement of the law that we have got. Labor courts, boards of conciliation—put them in the waste-

* Abstract of address of J. G. Bradley, president Buffalo Creek & Gauley Coal Co., Dundon, W. Va., before the American Mining Congress, Cleveland, Ohio, Oct. 12, 1922.

paper basket! Give the man who wants to work and who has the right to work the protection which he deserves—to work. There wasn't a time during this strike in the anthracite and bituminous coal industry that the mines could not have been manned by men who wanted to work, but they were afraid—afraid that they would be massacred, as they were at Herrin.

The public of the United States doesn't realize the crime that your union operators and the United Mine Workers have perpetrated on you. The public of the United States doesn't realize that the price of fuel for the future is today in the hands of the labor obligarchy, which has every intention of emulating Lenine and Trotzky; they are jealous because they haven't beaten them to it. And when you get the entire fuel resources of a nation in the control of such an unscrupulous, small group of men, you can sit around the table and say, "Now, John, you shouldn't do that," but it will get you nowhere.

Why should the public allow us to operate our mines if we haven't got the gumption to fight for our customers? They had better make their deal directly with the labor oligarchy; no use in counting us in. Why give us our profit? What have we done to earn it?

Before there is any other situation such as we have just come through, before another first of April, let us pray to God for the sake of the 110,000,000 people of the United States, who were held up by those controlling that 500,000—just as the highwayman in the night holds up the express crowded with people, so the leaders of this labor oligarchy have held up that 110,000,000—yes, let us see, that these high-paid public officials enforce the law; let us see that the public knows the situation so that they will demand that that law be enforced for their own protection.

Michigan Legislature Expected to Pass Fuel Bill Similar to New York's

Michigan's Legislature assembled in special session Oct. 10 to consider legislation to regulate distribution and cost of coal in the state and the Senate on Oct. 12 by a vote of 24 to 4 approved the measure submitted by the state's administrative officers, after slight amendments. One of the modifications limits application to coal and coke, releasing wood, oil and other forms of fuel, and another change eliminated authorization for appointment of a salaried fuel administrator.

The administration bill encountered rougher going in the House. It is predicted, however, that the House will pass the bill in modified form and that House and Senate will then harmonize the efforts of the two bodies.

The measure is modelled quite closely on the New York State law, though its provisions are said to be less drastic. It contemplates a system of licensing dealers and provides for seizure of coal or coke in possession of dealers.

ARGUMENT ON THE THREE SETS OF SUITS involving the validity of the Pennsylvania coal tax and valuation laws will be heard by the U. S. Supreme Court Nov. 13. Both sides urged that these test cases be expedited, so that if the decision of the Supreme Court be adverse to the state, the Legislature may have ample time to adjust its actions, regarding appropriations and otherwise, in accordance with the ruling. The principal fight is against the tonnage production tax and in this case several New England states are preparing to intervene on the ground that they have primary interest because the tax would increase the cost of coal to their consumers.

INDICATIONS NOW ARE that the distribution situation will have reached a sufficiently satisfactory state by Nov. 22 to allow Federal Fuel Distributor Spens to return to his regular position on that date, when his leave of absence expires. It is expected, however, that some machinery will have to be kept operative until the first of the year. Since much of the distribution work, however, would be of a routine character, there is nothing in the situation now to indicate that this cannot be handled by members of Mr. Spens' staff.

Spens Will Not Attempt to Fix Prices

The Federal Fuel Distributor has no intention of attempting price-fixing. This was brought out at a conference between John W. Davis, special counsel for the National Coal Association, and the law officer of the Fuel Distributor's office. Mr. Davis in a telegram to A. M. Ogle said: "Counsel for the Fuel Distributor assures me that the Fuel Distributor has no intention now or hereafter to attempt the fixing of prices. All efforts will be directed to moving coal.

©Harris & Ewing

JOHN W. DAVIS

Former Ambassador to Great Britain, as special counsel for the National Coal Association, expressed the opinion that the price-fixing features of the Cummins fuel distribution act are unconstitutional.

He intimates, however, that in cases of clear extortion cheapest coal will be given preference. He is willing to meet any suggestion as to form or contents of the daily reports and urges co-operation by operators lest matters be thrown into state legislatures for more drastic laws. Personally I am of the opinion that the price-fixing features of the Cummins Act are unconstitutional, although recent decisions of the Supreme Court, notably those on rent laws, have been on questions of a similar character. I do not advise legal action until the Fuel Distributor or the commission takes some oppressive step. Until then I think the general attitude should be co-operative."

Denies Ohio Coal Will Be Forced Into Markets Outside the State

Emphatic denial was made by Commander H. H. Bouson, federal representative in Ohio of the Federal Fuel Administration, to reports that Ohio-mined coal will be forced into interstate channels, thus compelling Ohio dealers to buy from other states at exorbitant rates, because of the Ohio emergency control system.

"Statements to the effect that Ohio's fair-price list would deprive the people of this state of coal are not founded on fact," Commander Bouson avers. "Definite instructions on that very point reached us recently. State Fuel Administrator Neal, on his recent visit to Washington, was assured that any effort to evade the Ohio law through interstate channels would meet with a sharp check from the federal authorities."

ON PAGE 601 of *Coal Age* last week the Ohio fair-price schedule by districts contained an error in District 7, which should read as follows: "The counties of Trumbull, Portage, Summit, Mahoning, Medina, Wayne and Stark and the County of Columbiana except the townships of Washington and Yellow Creek, $4.86."

Coal Wholesalers Express Satisfaction With Personnel of Coal Commission

Wholesale coal dealers generally regard with satisfaction the personnel selected by the President to compose the United States Coal Commission and believe that considerable good will result from the fact-finding proceedings, according to Ira Cochrane, acting commissioner of the American Wholesale Coal Association.

Information received at the association's headquarters in Washington indicates that domestic demand, applied to bituminous coal only, is weaker than usual, which is attributed to late warm weather and to the expectation of many domestic consumers that prices will decline.

Transportation still is the limiting factor, as reported by the association, but Acting Commissioner Cochrane expresses the belief that the railroads as a whole have been performing remarkably well under the conditions with which they have had to contend.

Functioning of the Federal Fuel Administration thus far has been highly pleasing to the association of wholesalers, as the normal flow of coal traffic has been preserved without the confused haulings that were feared might result.

Rehearing of Coronado Case Denied

Rehearing of the Coronado coal case was denied by the U. S. Supreme Court in a ruling from the bench Oct. 9. Unless the original plaintiffs institute a new suit in the coal court, no other move is possible in the case.

In this case, a suit for damages against the United Mine Workers of America brought by the Coronado Coal Co. and others because of destruction of mine property in Arkansas during a strike, the Supreme Court on June 5, last handed down a decision of far-reaching importance, holding that labor unions, although not incorporated, are capable and liable for damages which result from acts of their members on an authorized strike in matters affecting interstate commerce. The court held, however, that it could not sustain an award of damages in this case because it had not been established to the satisfaction of the court that the acts were in restraint of interstate commerce during an authorized strike.

In the petition for rehearing the original plaintiffs contended that interstate commerce was involved because the damage was inflicted to prevent competition with mines in other states with which the union had contracts. The petition further urged an award of judgment on the ground that the lapse of time since the damage was suffered would "inevitably embarrass the further prosecution of the case."

Argument has been heard in the case of the Corona Coal Co. vs. the Southern Railway, involving assignment of cars to coal mines.

The case of the Hillsboro Coal Co. has been passed to be argued later.

Floating Coal Down the Ohio on Artificial Waves Leaves Many Barges Stranded

Government engineers have had considerable success at various times in creating artificial waves in the upper Ohio River to bring coal down from West Virginia mines toward Cincinnati, but a wave started Oct. 2 to bring down 50,000 tons of coal was a failure. The river is lower than at any time in fifteen years and when the pools of water above the various dams were released they spread out and moved so rapidly that the artificial stage didn't hold long enough to enable the tows to make much headway.

Out of ten fleets started all but one towboat got into trouble early and the Kanawha coal fleet is scattered at various points on the Ohio River, and will have to wait for a considerable rise before proceeding. In the meantime they may be laid in for the winter, as there have been seasons when there were no heavy rains or big river rises until after the first of the year.

One steamer lost two barges near Dam 28, when they hit bottom and sank. The steamer *Mitchell* went aground off Ironton, Ohio. The *Island Creek*—a towboat, which had been stranded on a bar below Maysville, Ky., for a week, managed to get off when the artificial wave reached her. She had a line of barges carrying between 5,000 and 6,000 tons, and at last reports was expected to reach Cincinnati. The *R. P. Gilham* reported tied up at Lock No. 35, near Maysville, where she would hold her tow until a better stage of water is available. Handling a coal tow is no easy matter with a good river, but with shallow water and an artificial wave, creating a strong current, towing becomes a serious problem. However, previous efforts to bring out a lot of coal through artificial waves created by manipulation of locks and dams have been successful.

Railroads Consume 300,000 Tons Less of Coal During July Than in June

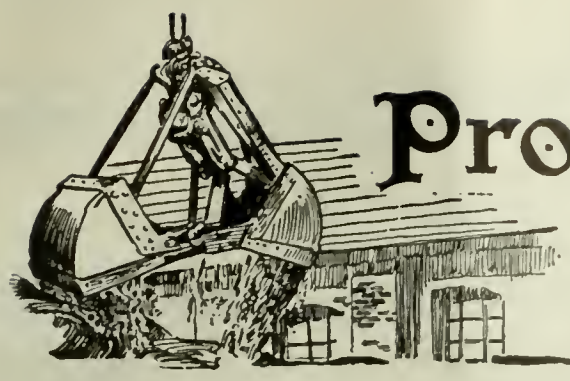
Class 1 railroads consumed 6,586,000 net tons of coal during July, 1922, as charged to account 394, compared with 6,892,000 tons in July last year, according to a report of the Bureau of Statistics of the Interstate Commerce Commission covering 182 steam roads. June consumption was 6,787,000 tons. For the first seven months of 1922 these roads consumed 51,661,000 tons as compared with 52,514,000 tons during the same period in 1921.

The delivered cost per ton in July was $4.32, or 33c. above that for July, 1921. The per-ton cost for the year to July 31, however, was only $3.67 as compared with $4.37 during the corresponding period of 1921.

Fuel-oil consumption continues to gain. During July 120,626,000 gallons were used, as compared with 114,911,000 gallons in July, 1921. The figures for the first seven months of 1922 and of 1921 were 831,923,000 and 811,719,000 gallons respectively.

End Strike at Connellsville Union Mines

Non-union mines in the Connellsville coke region are all gaining substantially in output and man-power and the car supply is improving. The Taylor Coal & Coke Co. at Searight resumed operations during the past week.



The strike at union mines along the Monongahela River has been settled. As reported last week, workers at the Diamond mine of the Diamond Coal & Coke Co. went out because they were asked to load Mather Colliery Co. (open-shop) cars, and the Lilly Coal & Coke Co. men quit because they were loading Pittsburgh Steel Co. barges. The Diamond miners stayed out only one day, but as a result of a meeting Sunday of several mines along the river the National Mining Co. mine, below Lilly, went out Oct. 9, and stayed out three days. They went back to work Oct. 12 and the men at Lilly went back the following day. The National Mining Co. is a union subsidiary of the United States Steel Corporation and the men quit rather than load Carnegie Steel Co. barges.

According to unofficial information there has been a steady return of men to work at the Leisenring No. 1 plant of the H. C. Frick Coke Co. during the last two weeks.

Restrictions on Bunker Coal Raised

An order raising the restrictions on bunker coal was issued Oct. 13. During the time that the restrictions were in force some 200,000 tons of coal which ordinarily would have gone to foreign ships has been diverted for American use. The accumulation of coal at ports and the rapid decline in prices at tidewater were regarded as sufficient indications that the regulation, which frequently imposed a severe hardship on shipping and on dealers and operators, could be cancelled.

THE NAVY DEPARTMENT has given permission to the City of Boston to use the coal unloading facilities at the Boston Navy Yard for coal consigned to the municipal coal yard. The plans for this municipal enterprise have been laid before the Federal Fuel Distributor and he has interposed no objection to the project.

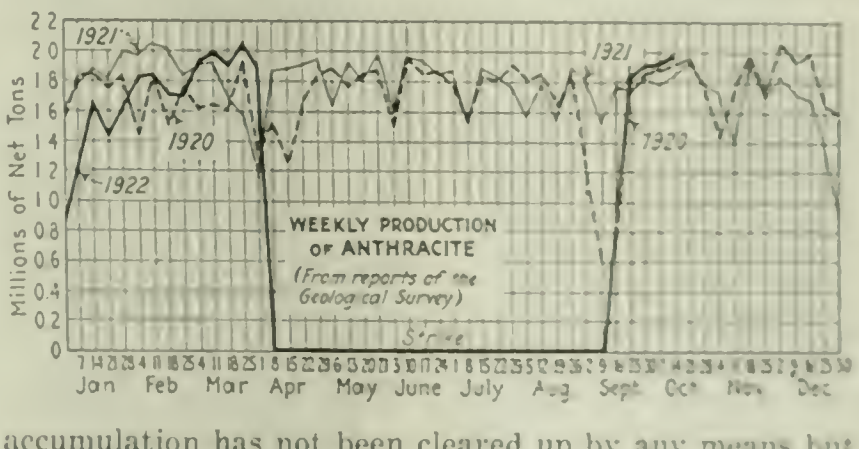
Production and the Market

Weekly Review

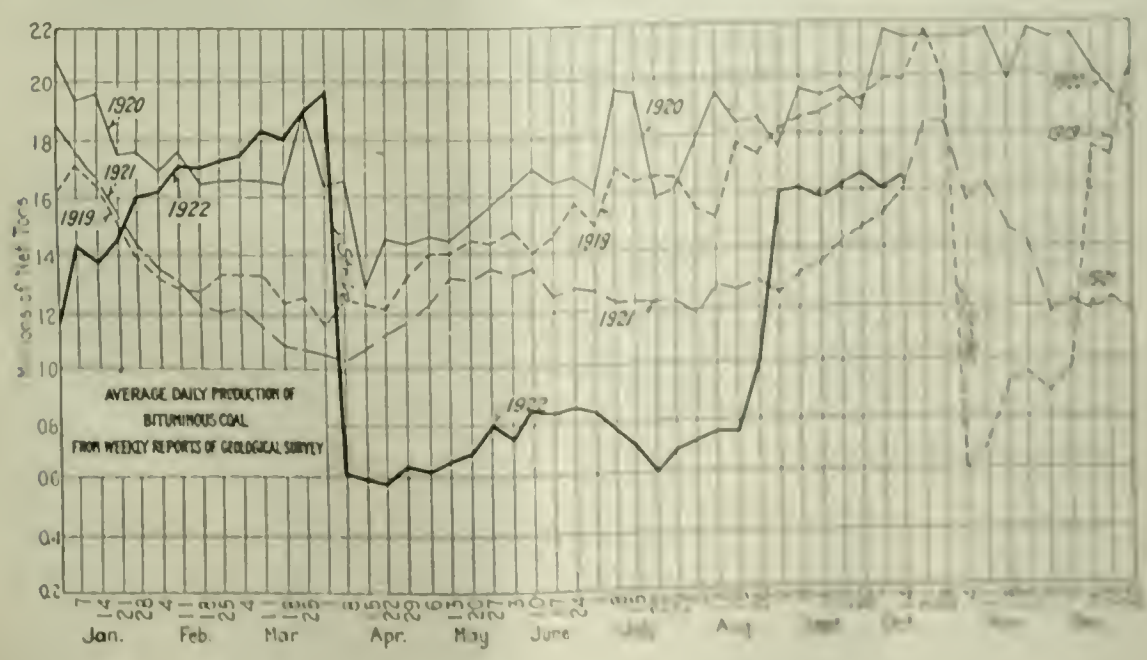
Coal prices are still slipping downward and demand is but little improved, though signs are not lacking that the bottom will be reached before Nov. 1. Colder weather has strengthened the demand for domestic bituminous coal and this has been reflected in a better steam call. Industries normally go into the winter with increased stocks as a bulwark against poor receipts when transportation conditions are bad. This year has been the exception and buying has been on a hand-to-mouth basis. The prospect of still lower prices is now delaying purchases, but the recent touch of cold weather has shaken this resolve in a manner which indicates further buying action in the near future.

Demand has not yet revived sufficiently to hold prices. *Coal Age* Index of spot bituminous coal prices stood at 368 on Oct. 16 as compared with 380 a week earlier. This corresponds to an average mine price of $4.45, a drop of 15c. in the week. The previous week registered a decline of 29c. The trade expects the end of the price drop, which has been in progress since the middle of August, to await the advent of real cold weather, bringing with it deferred industrial and domestic demand.

Realizing Values, More Consumers Enter Market



Some large consumers have realized the good values now offering, and the past week has seen heavier takings by the railroads and utilities. The rank and file of buyers, however, have not yet appeared in the market, except for day-to-day requirements.



The market ranges from excessive dullness in New England to mild activity in the Chicago territory, which appears to be awakening to the fact that the time is short to obtain additional tonnage before the usual seasonal transportation difficulties appear. New York and other North Atlantic sections are experiencing better coal receipts via Tide and all-rail, offsetting the declining volume of British coal. Hampton Roads is in oversupply because of transportation congestion in the West, and coastwise factors are plying New England and North Atlantic centers with all the tonnage the market will stand, to the detriment of the all-rail fuels. Pittsburgh, Cleveland and Detroit are in more comfortable supply and inquiries are picking up with the recent cold spell.

Much transportation progress has been made during the past week. It has been possible to move large amounts of coal which were being held on sidetracks and in yards between the mines and destination. This accumulation has not been cleared up by any means but most of the railroads are beginning to make an impression on their accumulation of loaded cars.

Despite the large amount of coal still being held on railroad sidings, reports to Washington indicate that there are many cases throughout the country where coal is being sold for demurrage charges. Demands for priority have practically ceased.

Retail distribution of anthracite is progressing smoothly. Strict rationing of supplies has spread considerable tonnage over the East, but Western markets are obtaining little fuel. The Lakes have taken approximately 200,000 tons of hard coal since the strike ended, and it is not expected that the Northwest can

possibly obtain more than 50 per cent of its requirements to make this move.

The approval of the Federal Fuel Distributor, acting jointly with the Pennsylvania Fuel Commission, has been given to the report of the Fair Practices Committee, which recommends that, in the case of a number of the independent operators who have announced that they will observe a maximum price of $2.25, the committee's investigative efforts be deferred for the present in order that its efforts can be concentrated on cases where prices in excess of $2.25 are being charged.

BITUMINOUS

"Complete returns on soft coal production for the week ended Oct. 14 will show about 8,900,000 tons," says the Geological Survey. "During the five weeks just closed the output has been at an almost uniform rate varying little from an average of about 8,700,000 tons.

"The number of cars loaded on Monday, Oct. 9, reported by the railroads, was 40,209, the largest reported this year; but on Tuesday loadings fell off to 29,239 cars, a figure exceeded on several Tuesdays since the close of the strike. The total cars loaded on the first four days of this week shows an increase of 3.9 per cent as compared with the same days of the week before. Full returns on loadings for the week are expected to show an output of 9,800,000 to 10,000,000 tons."

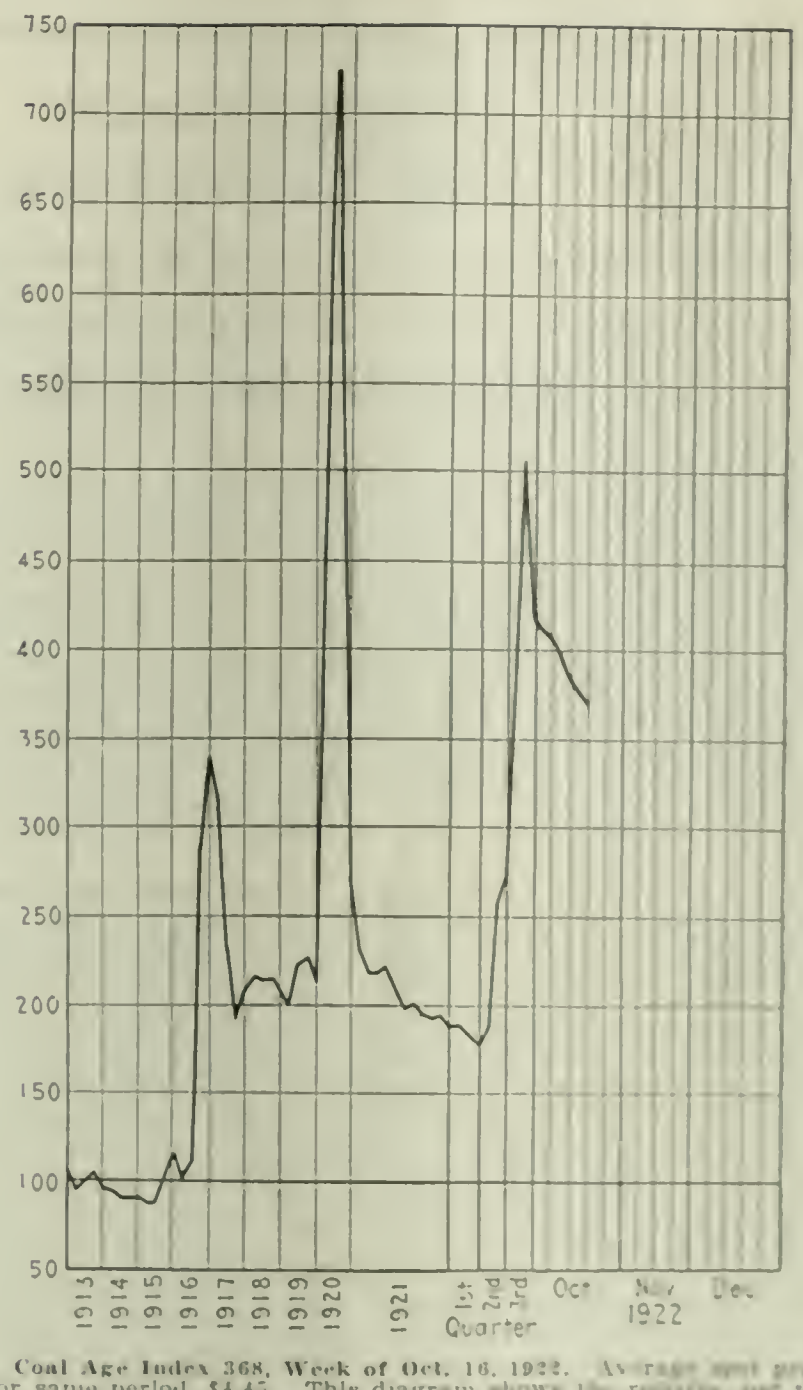
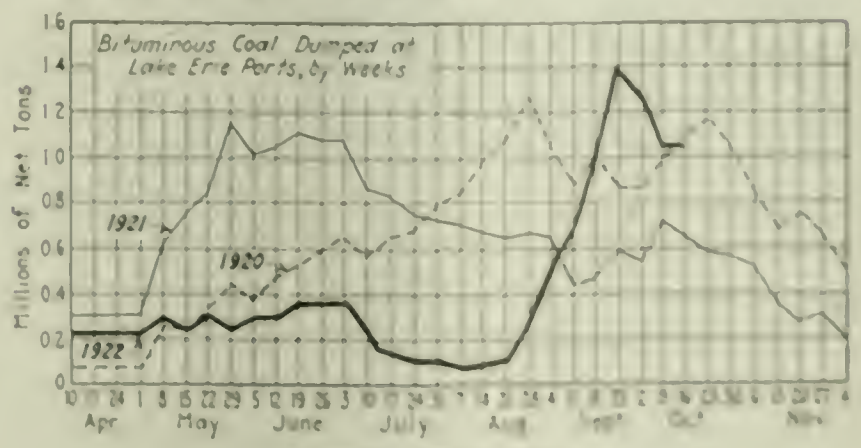
	Surplus Cars All Cars	Surplus Cars Coal Cars	Car Shortage	
Sept. 30, 1922	5,843	3,486	130,325	32,148
Sept. 23, 1922	11,292	6,975	107,666	25,332
ame date a year ago	172,420	98,048	.....	.....

the week ended Oct. 12, practically unchanged from the preceding week. Coastwise markets—the bulwark of the Roads shippers—are in much softer condition and prices are being shaded to close sales. New England especially is in such comfortable supply that it is difficult to see where any considerable inquiry can develop before Jan. 1.

Lake dumpings were 1,053,873 net tons during the week ended Oct. 16, as compared with 1,179,298 tons in the preceding week. The season's Lake movement to date is 12,422,474 tons; last year it was 20,282,948 tons.



ANTHRACITE



Production of anthracite continues to increase. The output during the week ended Oct. 7 was 1,959,000 net tons and loadings for the first four days of last week indicate an output of about 2,000,000 tons in that period. Much inconvenience is being caused by the slowness in the movement of steam sizes. There are now more than 150,000 tons of these coals between the mines and Eastern cities.

COKE

Production of beehive coke continues to increase slowly. The output during the week ended Oct. 7 was 171,000 net tons, 11,000 in excess of the preceding week. Coke prices are at last breaking, but the supply is still too costly and limited to tempt additional blast furnaces to resume.

Coal Age Index 368, Week of Oct. 16, 1922. Average spot price for same period, $4.45. This diagram shows the relative and the actual prices on fourteen coals, representative of nearly 75 per cent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions [illegible] and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918" published by the Geological Survey and the War Industries Board.

ESTIMATED MONTHLY CONSUMPTION OF COAL FOR MANUFACTURE OF COKE

(Net tons)

	Commercial Production Ovens	Commercial Beehive Ovens	Total Coal Consumed

Foreign Market And Export News

Continental Orders Replace American Business On British Market: Prices Strong

British admiralty and large dogs are heavily loaded for October and early November delivery. A number of the leading owners are out of the market. Continental demands are active and substantial exports are being received from South America. With the exception of bunker coal for which there is a steady demand, other sizes are abundant and easy.

Freights during the week ended Sept. 28 made another slight gain, according to a cable to Coal Age, advancing from 1,344,000 tons to 3,177,000 tons.

Little business is now being done with the United States in South Wales, though Canada continues to be a good customer. The class of coal in which the business is being done is of the dry steam variety, which is evidently being employed as a substitute for anthracite. These Canadian orders have served to steady the market, and the downward trend of prices in Wales appears to have been arrested. In one or two cases prices have been cut to encourage the Continental and South American buyers.

In one week at the end of September a falling off of 45,000 tons was registered at the Welsh ports, chiefly owing to the slacker American demand. The European shipments also were lower, while the Admiralty orders were more than doubled.

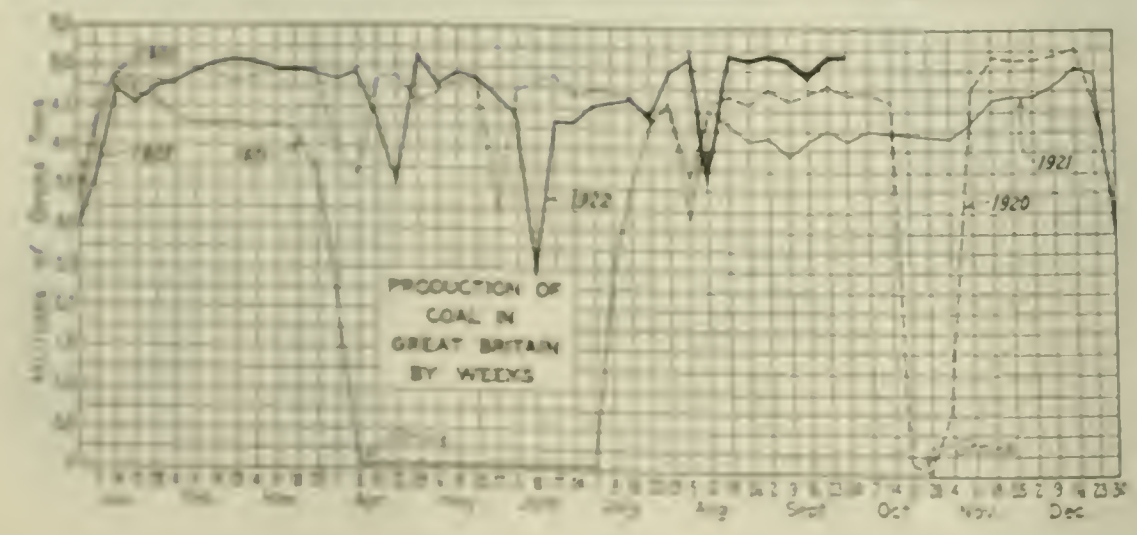
The Yorkshire field continues to be steadily occupied. The pits are now able to sell all the best steam coal they can produce and prices are steady. The industrial demand is strengthening a little and the public utility companies are laying in large stocks. Operators are accepting easy prices for unscreened sorts to keep their pits clear. The chief European destinations for Yorkshire coal are Germany, Norway and Sweden.

Germany is a very active buyer in the Newcastle district and the orders from this source and from other European countries about compensates for the loss of a great part of the American business. Among the orders received in this area are one of 180,000 tons of steam coal over the next six months for the German State Railways, 5,000 tons of best Durham steam coal for shipment during October for the Norwegian State Railways, 2,000 tons of special Wear gas coals for Randers at 30s. 5½d., and smaller orders from other European railway companies.

There is very little change in the Scottish market. One or two shipments have been made to America and Canada, and there remains a small order to fill here and there in this direction.

French Fear Domestic Coal Shortage

Coal of the Nord and Pas-de-Calais has become more active still and domestic demand is especially pressing. A few collieries are restricting their shipments in provision for a strike which may break out before Nov. 1. A shortage of domestic coal is apprehended as soon as winter sets in.



The outcome of the present conflict between operators and men may be determined when the French Parliament reassembles. Should, however, collieries of the Nord and Pas-de-Calais obtain no relief from their present cost price they will again be in none too enviable a situation as soon as British competition reasserts itself.

Mines of the Nord and Pas-de-Calais have published their official schedule of prices for the fourth quarter, which is the same as for the third quarter, less summer bounties which are now off.

FRENCH MINE PRICES

[illegible]	40fr.@ 58fr
[illegible]	87fr.@ 107fr.
Raw of mine 26-25%	63fr.@ 66fr.

Briquets, pea	105 fr.
Washed pea	70fr @ 92fr.
Washed small	57fr.@ 74fr.
Washed nutcoke	105 fr.

The adjusted price of German coke delivered to French blast furnaces by the Société des Cokes de Hauts-Fourneaux has been maintained for October and November at the same limit as for September—95fr. at the Franco-German frontier. On the other hand, French collieries of the Nord and Pas-de-Calais have reduced the price of the metallurgical coke they supply to the said Societe, in view of its being pooled with German coke, to 92fr. for November from a previous limit of 95fr.

Coal Paragraphs from Foreign Lands

BELGIUM—Activity in the coal market is still great in both industrial and domestic descriptions. Large orders have been received from Paris, Switzerland and Holland.

SPAIN—Since the end of the strike in the Asturias, Barcelona has received over 50,000 tons of that coal, but demand continues strong. A good number of industries are studying the use of Asturian coal in place of British owing to the rise in price of the latter.

The following are among the latest mine quotations of the Central Hullera Asturiana: Screened and lump, 50@52 pesetas, small gas, 35, small steam, 33, metallurgical coke, 60@67, blast furnace coke, 38@40.

Cooler Weather Fails to Stimulate Coal Market

Prices Firm Only on Good Grades—With Car Shortage Acute, Shippers Confine Efforts to Regular Trade—British Coal No Longer a Market Factor.

Colder weather has failed to cause much stir in the coal market. Only good grades are salable at firm prices, while the poorer qualities are forced to sell at lower figures. Shippers are not active in soliciting orders, as they are barely able to take care of their regular trade, so acute has the car shortage become.

Some large consumers have realized the good values now offering and are taking in a limited tonnage for storage, but the average buyer is still restricting his orders to current requirements. British coal has ceased to be a market factor, but this has been replaced by heavier American receipts, both by Tide and all rail.

PHILADELPHIA

No improvement is noticeable in the bituminous trade, the consumer holding off as usual, while the producer is not soliciting trade, being busy distributing tonnage to his regular trade. Car shortage is still a very serious problem.

Quite some complaint is heard of poor quality coal coming into the market, but this usually springs up when coal of the better grades is not to be freely had. With the consumer's attitude of waiting for lower prices, he is at the same time inclined to become more critical as to quality. The railroads now seem to be accumulating better stocks of engine fuel and are reported to have close to a month's supply ahead, or in prospect.

Prices are still inclined to weaken. Nothing seems to shake the consumers' confidence in much lower prices and they congratulate themselves that they are slowly achieving this result. Contrasted to this attitude we know of some large consumers who have contracted for blocks of tonnage of the best coal at prices that closely approximate the present spot market.

At Tide there is only ordinary business in bunkering, and only a minimum of shipments for export. British coal also seems to have ceased to be a factor in the market.

CENTRAL PENNSYLVANIA

Car shortage is about the only thing interfering with production. On the lines entering the central region and in the region reached over the New York Central, the supply of cars is only 30 per cent of requirements.

The miners are working in full force throughout the union areas. The non-union mines are rapidly gaining in car loadings and to all intents and purposes the strike in the non-union operations is over. The Berwind-White Coal Co., at Windber, where the battle was most bitterly contested, is making daily gains in production.

Prices quoted at the mines are: Pool 10, $4.25@$4.50; Pool 9, $4.50@$4.75; Pool 1, $4.75@$5. Lower grades are quoted at $4.

BALTIMORE

Now that winter is approaching rapidly the seasonal jump in demand for storage in anticipation of traffic congestion to come later might well be expected. So far this has failed to materialize and even the larger industries are going ahead without much reserve.

The easy market has had the tendency of preventing any further jumps in price and in some cases there has been a recession, this being especially true of gas coals. With the call for soft coal coming from sources that normally use only anthracite there is noted a particularly strong demand for lump but there has been so little screening done that dealers are at a loss to know where to get the lump for this trade as they recommend.

The situation has strengthened the call for English coals, even though they are selling much above the American lump. Following the importation of 88,789 tons of British coal at Baltimore from the latter part of August till Oct. 15, it is reported that other ships will shortly arrive. The October arrivals were two with a total of 13,586 tons. The first export movement noted since last April came on Oct. 9 when a schooner sailed for Cuba with 2,434 tons. The last previous export movement was on April 10, when 2,916 tons cleared for Cuba.

NEW YORK

No buying to amount to anything has come into the market and prices show little tendency to advance. At the same time the decline seems to have been checked, in the better grades of coal at least. There has been no improvement in the situation. If anything, it is worse.

With such a state of affairs prevailing when the railroads have nothing to contend with in the way of adverse weather conditions, it is easy to surmise what will happen when low temperatures make their appearance. Yet the average consumer is making no effort to get stocked up against such a time. The hope of getting coal cheaper by waiting is the actuating motive in nine cases out of ten.

Few of the operators are willing to commit themselves over a period of months at the prices now prevailing in the spot market. They are fully as confident as the buyers when it comes to predicting the future course of prices, the only difference of opinion being as to which way the cat is going to jump.

In all-rail territory, owing to the scarcity of orders, shippers have been sending somewhat more coal to Tidewater than the local market can absorb readily. Some of it has got on demurrage and is causing some unsettlement. Between 1,500 and 1,600 cars were reported standing at the piers at the end of the week.

Current quotations are shown in the Weekly Review.

UPPER POTOMAC

Mines are not troubled so much by a shortage of cars as they were during a part of September and hence it has been possible to increase production somewhat on the line of the Western Maryland. Georges Creek production is not being increased materially but the deficiency is being taken care of in the Meyersdale field where many strikers are working. Aware of that fact, Georges Creek operators are bringing eviction proceedings so as to make room for men who will work. As it is necessary to dump all coal produced into Eastern markets the price is off.

FAIRMONT

Changes in the Eastern market have been very rapid and peculiar. Much coal billed to the Lakes is being thrown back on producers who have to find a market for it in the West and that is creating confusion. The B. & O. is assigning cars and that is only aggravating conditions connected with an acute car shortage. The Tidewater demand is extremely light. Coke production is being increased.

South

BIRMINGHAM

Buyers of steam coal are maintaining a rather indifferent attitude toward the market. Consumers are placing orders for immediate needs only with requests for prompt shipment, and are apparently evidencing no desire to stock coal. The principal demand is coming from small industries and utilities in Alabama, Mississippi and Georgia, while some run of mine is being sold for heating public buildings.

A few days of cool weather has created a more insistent demand for domestic. Conditions incident to an increased supply have not improved, the light demand for steam, together with the shortage of equipment retarding both production and movement very materially. Prices for all grades of domestic are stiff. Quotations on steam have eased off to some extent.

Car supply on the Southern the past week has shown some little improvement, but the situation as a whole is little if any better than a week ago. Production is around 345,000 tons per week.

VIRGINIA

Virginia mines are recovering in a measure from the handicap of a car shortage. The output has been increased to 66 per cent, with C. C. & O. mines leading all others. Although there is not a stiff demand for coal, no losses have been sustained so far from a lack of orders, owing to the shortage of equipment.

Anthracite

Rigid Domestic Rationing Eases Tension in East

Western Markets Still Await Hard Coal—Too Late to Avert Shortage in Northwest—Independent Quotations Are Reduced—Steam Sizes Burdensome.

The domestic situation is more reassuring as strict rationing has distributed a little coal over a wide area of the East. Western points are not expected to receive much tonnage for another 60 days. The Lakes are beginning to get hard coal—200,000 tons since mining was resumed—but it is realized that winter will find the Northwest far short of its requirements.

Independent quotations show a lower range. There is less tendency to buy $12-coal, and the majority of the independents are adhering to the $10.25 maximum for the family trade. Steam sizes are in heavy oversupply and the market has softened perceptibly.

PHILADELPHIA

Cold weather has brought a snap to the retail trade that is not denied by the dealers. The movement is calling strongly for coal. Most yards are on the verge of emptiness. To complicate the situation many consumers have been found who have duplicated orders and often refuse coal when it is delivered.

Wholesale prices seem to be reaching a stable basis now, as the efforts to bring the independents into line by the fuel commission seem to be nearing success. However, it is still believed that a few of the small independents will continue to charge $9.50. So far nothing has been given out as to the policy of two or three concerns who were reported to be asking $12 to $13. It is the belief that there is no law by which the commission can set prices, and some intimate that it is illegal if they ever attempt to.

Many soft spots have developed in the steam trade, and while the companies are still able to dispose of their production without resorting to their storage yards, the independents are finding it difficult to move theirs. Price shading is in evidence.

NEW YORK

The substitution of all harrows and soft coal is blamed in part for the accumulation of steam coals. They are looking up on the producers to assist that is showing no little promise although it is realized that the turning on of steam heat will create a better demand for buckwheat.

The quantity of steam sizes at Tidewater is not only demoralizing the market, but it is causing delay in unloading cars. Barley is the weakest size.

It is a seller's market in the sizes above pea and a buyer's market in the sizes below. While there is a strong demand for the coal at the circular prices, retailers are not quite as willing to pay upward of $12 a ton as they were for a time after the resumption of mining.

Consumers are not quite as clamorous as dealers had feared they would be. A large tonnage of soft coal has been placed in apartment houses, business buildings, schools and public institutions of all kinds. This has made more tonnage available for use of the small consumer, and with a careful rationing of the supply a large percentage of the public will have a little anthracite by the time it is actually needed.

BALTIMORE

Dealers are being swamped with orders now that there is a snap in the atmosphere. Less than 60 per cent of immediate needs, entirely outside of any coal for storage over the winter is now running here. Dealers are sticking to small lot deliveries but even this does not meet the situation as consumers generally are refusing to take bituminous coal as a substitute.

In view of the fact that Baltimore dealers are still getting practically only independent coal at high prices the majority of dealers are still forced to sell the more popular grades at $16 per gross ton. Officials of the Maryland Distribution Committee who have been investigating conditions have openly laid the greater part of the trouble to this fact.

ANTHRACITE FIELDS

The mines are all working to capacity and they have not been hit as badly by the car shortage this week. There are no labor disturbances anywhere in the region.

There is no demand for the steam sizes. Some of the companies are complaining about this.

BUFFALO

The demand keeps up, but people understand the situation and do not try to get coal in quantity. Nobody is getting more than about half as much as was received a year ago. Lake shipments are also cut down.

Lake shipments last week were 71,700 tons, of which 29,500 tons cleared for Milwaukee, 21,200 for Duluth and Superior, 14,200 for Chicago and 7,500 for Sheboygan. Freight rates are 50c.@55c. to Chicago, 50c. to Milwaukee, 45c.@50c. to Sheboygan and 40c. to Duluth.

BOSTON

Shipments are slowly dribbling through all-rail, and practically every well-connected dealer has had a fair month's quota since mining was resumed. Tidewater dealers have perhaps had better receipts in proportion, but this is due rather to eccentricities of car-supply than to any design on the part of shippers.

Prepared sizes are being distributed in sparing amounts, but during the mild weather there was very much less public anxiety in evidence than was expected. Householders have apparently concluded that somehow or other they will manage to get through the winter and they are gracefully accepting the situation. Or, it may be, the situation is not as distressful as has been made out.

Coke

UNIONTOWN

Coal buyers are retaining their advantage in the market by limiting purchases to a minimum and operators, faced with the problem of keeping their working forces together are forced to close sales at figures they claim out of proportion to present production costs. The car situation is a bit easier. Because of the railroad situation, the carriers are keeping close check on cars placed for loading and are demanding that a consignee be named as shortly as possible after a car is loaded. That condition also helps to soften the market.

The strike of Connellsville miners has ceased to be a matter of public interest. At practically all the larger plants there are groups of "hold-outs" but at the same time many of them have returned to work.

The trade is quoting $3@$3.25 for steam coal. Three-quarter lump is $3.25@$3.50 with byproduct, $3.50@$3.75.

CONNELLSVILLE

The break in Connellsville coke prices has begun at last. A few days ago sales were made at $11 and more was offered freely at that figure without finding takers, resulting in some sales being made at $10.50. The market has ample room for further declines, since coke has frequently sold at less than its natural ratio to coal, according to the formula of 1½ tons of coal at the market price plus the cost of coking. With the coal market at $3.50, and the coking cost, with the present high wage scale, about $1.25, the formula would make $6.50 as the coke price.

Foundry coke has also declined, but somewhat sluggishly as some foundries, not well posted, have been paying close to the old prices. The market is now quotable at $12@$12.50.

The condition no longer obtains of there being an indefinite number of blast furnaces waiting to resume and willing to pay the open market price. Pig iron consumers in general evidently are unable to pay present prices, while furnaces could not make lower figures except with cheaper coke. As furnaces get into operation deliveries are made on old contracts and thus the need of consumers to buy pig iron in the open market is reduced.

The *Courier* reports coke production during the week ended Oct. 7 at 91,100 tons by the furnace ovens and 35,250 tons by the merchant ovens, a total of 126,350 tons, an increase of 7,670 tons.

BUFFALO

Demand continues light, for the local plants are running actively and they are able to supply the furnaces pretty well. At the same time the coke situation at the big Pennsylvania oven centers is not good.

Chicago and Midwest

Regional Market Seems Ready for Upturn Now

Domestic Demand Continues Heavy and Steam "Buyers' Strike" Gives Signs of Breaking—Car Service Improves Only Slightly.

Continuance of a heavy domestic demand and very little, if any, improvement in car service by the roads keep the markets of this region about on the level of last week. While it is true there is no rush of steam buyers and a good deal of those grades are getting into distress almost daily, yet railroads are taking heavier tonnages for their own use and other big steam consumers are displaying more interest in deliveries on contracts. With the approach of colder weather the coal industry gets into a better position temporarily—only to prepare gloomily for greater difficulties later on.

Car supply throughout southern Illinois is still in the neighborhood of 30 per cent, while northern and central fields are down to 45 or 50 per cent—and glad the service is no better. West Kentucky is running about 20 per cent of the time and Indiana fields somewhat less than half time. Prices generally throughout this section are unchanged from last week, except in Kentucky where a slight weakening of mine run and screenings was noticed.

CHICAGO

A tightening up of the domestic market, after the slight softening, and a certain uneasiness on the part of some of the big steam buyers who are still "on strike" are signs which coal men are reading just now. Many retailers who have not attempted to stock anything, are trying to do so now, finally concluding that domestic prices are not due for a drop. Householders who have been following to the letter the retailers' advice to buy only in small quantities, are now asking for a good deal more than the yards can deliver. The result is a considerable backwatering of orders followed by an epidemic of coal prescriptions signed by many doctors.

Some hard coal has reached here but only a little smokeless. The anthracite mine price quoted here ranges $8.50@$9.50 on buckwheat and pea and up to $12 on the larger sizes. Smokeless mine run and lump sells for $6.25@$7 except the little which is jobbed.

Several elements are combining to take some of the rigidity out of the "buyers' strike" among big consumers of steam coals. One is that a good many short contracts for oil expire at once and many may not be renewed. Another is that few industries are stocked with coal and the third is that it seems more apparent every day that the strangulation of rail transportation will not be relieved soon and cold weather with an inevitable rush of demand is due at any moment. For these reasons there are fewer coal contract cancellations nowadays.

WESTERN KENTUCKY

The general markets are weaker and with industrial consumers refusing to stock, and retailers buying only for immediate demand, producers are finding it harder to sell coal. Unless there is material improvement soon in demand either for domestic or steam, any increase in car supply just now would find the market slumping further. The reported car supply averages around 20 per cent on the L. & N. railroad, and about 35 per cent on the Illinois Central.

Many coal men here believe that retailers have kept consumers from stocking, in the belief that prices would be lower, and that with cold weather a heavy demand will develop for prepared. Right now there appears to be an increasing tendency for domestic consumers to take up better grades of clean mine run for heating use.

Lump coal which has been strong at $5 and over, is now quoted at $4.75 in some instances for off-grade, while supplies are being offered at $4.85@$5.25 in quantities. Mine run has broken to $2.75@$3.25 and screenings, $2.75@$3.

SOUTHERN ILLINOIS

Lack of rail equipment and failure to sell steam sizes stand out strong as obstacles in the Carterville field in southern Illinois. At one or two places a little steam is held without billing and if cars were plentiful there would be a lot of this stuff on hand. Railroads are buying again, however, and the car situation is just a trifle better than it has been. The demand for lump, egg and nut is unusually good.

Somewhat similar conditions prevail in the Duquoin and East Jackson field. In the Mt. Olive district working time is two or three days a week. The railroad tonnage is heavy. Several trunk lines through this district are tied up, especially the Wabash, which is unable to deliver to the terminal at St. Louis on account of lack of motive power on trunk lines out from St. Louis, principally the Frisco.

In the Standard field lack of orders for lump has seen mines with no-bills on track at night. The steam situation is unusually bad. Railroad tonnage is fair, everything considered.

ST. LOUIS

A little more seasonable weather has started the domestic demand on the cheaper grades. The light tonnage of Carterville is going at a premium of $5.50@$6 at the mine. The retail price is $9.50. Mt. Olive, which is available as a rule, is $4 at the mine and retails at $7.50. This makes Mt. Olive the popular coal

Country domestic and steam demand are both picking up. Locally steam is not selling, except from day to day. Very little coal is piling up in storage. Railroad movement has shown some improvement though hundreds of cars are held in East St. Louis on account of the inability of the Frisco and Missouri Pacific to handle them.

INDIANAPOLIS

Demand has been more active during the past week, due largely to the imminence of cold weather. Most of the demand is coming from the domestic consumer and retail dealers generally are limiting their sales to three tons in order to have enough to go around.

There has been no particular strength in the price situation during the past week, although there has been a fairly ready market at the established prices. Domestic coal of the Indiana grades is retailing around $7@$8.50, while foreign-mined coal, such as Pocahontas, Kentucky and West Virginia, is retailing around $11.50 for the prepared sizes, with about 50c. lower for mine run. Demand for steam coal is fair.

LOUISVILLE

Heavy rains for the past several days are resulting in better river stages and packets are resuming operations. A number of coal tows stranded in the upper Ohio are expected to reach Cincinnati on the rise and some of this coal will come to Louisville and sister cities. General demand is slow. Everyone appears to be getting immediate supplies and at present prices there is no stocking demand reported. When the Lake movement stops this will throw more production to the industrial and domestic consumers, and may ease prices.

Retailers are hot over the fact that there is a range of $2 a ton and more between mine run and lump. A few retailers who have their own screening equipment are taking advantage of the fact, but others are endeavoring to get domestic users to take mine run.

It is hard to sell coal now, not only locally but north of the river and in other sections. There is a little better rural demand than there has been, but it appears as if the country generally is anticipating lower markets, and is not worrying. Car supply is reported at about 20 per cent on most lines, with the Illinois Central attaining about 45 per cent.

Canada

TORONTO

The volume of business is light with conditions unsettled and prices variable. Limited shipments of anthracite received from the Lake companies are being retailed at $15.50 per ton, the price fixed by the Fuel Controller, but some dealers are obtaining supplies from independent companies and selling considerably higher.

The price of $ in lump in carload lots, f.o.b. destination, ranges $8.75@$10.25, and Pennsylvania smokeless about $9, retailing for $12. Steam lump retails at $15.50. Representatives of British coal companies are making a strong effort to obtain a footing in this market and prices are lower.

Eastern Inland

Seasonable Temperature Tends to Stabilize Market

Active Call, with Prices Up, for Domestic Coal—Condition Reflected in Steam Section—Car Situation Worse, Production Falls Further—Lake Congestion Slowly Clearing

More stability in the market has appeared with colder weather. Domestic coal is in active call with higher prices and the steam section gets a reflection of this. Prices on industrial fuels, however, are still weak. The Ohio fair-price list is driving much coal out of the state and causing an influx of "foreign" coal at advanced figures.

The car situation is worse and production has slipped down another notch. Old connections are being heavily worked and this leaves but little free tonnage offering.

Heavy Lake shipments have left a considerable tonnage of screenings, which are being absorbed with some price softening. The congestion at lower ports is clearing—cargo coal is being loaded faster than it comes in, and the 15,000,000-ton goal this season will be difficult of attainment unless Lake buyers become more active. It will be necessary to move approximately 1,000,000 tons weekly during the balance of the season to reach the above figure.

PITTSBURGH

Production continues at much the same rate as for several weeks past. There is somewhat louder complaint as to car shortage, this being due, apparently, rather to operators wishing to run at higher rates than to there being any decrease in the number of cars furnished the district.

The turnover in the spot market has decreased further. Consumers more or less supplied quite well by their regular sources of supply and there is little demand for odd lots in the open market. Prices have been softening and are likely to go lower unless there is a serious change in fundamental conditions. Consumers are exhibiting no disposition to stock coal and apparently expect materially lower prices when Lake shipments are completed.

The market stands at about $3.50 for gas grades of steam, $3@$4.25 for byproduct, $4@$4.75 for best gas, all mine run, and about $3.25 for best domestic 1½-in. lump.

EASTERN OHIO

Stabilization of the spot market resulting from a more plentiful supply of coal overtaking immediate needs and the lower temperatures prevailing throughout this section have combined to create a more general and widespread demand. Inquiries from retail dealers have significantly increased during the past few days and retailers are besieged with orders from domestic consumers, the majority of whom have delayed filling their bins in the hope that domestic fuels might be obtained at lower prices than those quoted some weeks back. However, some of the larger operators assert that because of heavy shipments to the Lake there is an abundance of cheap slack in the market.

Car shortage and transportation disability continue to occupy the foreground as the main hindrance preventing maximum production. During the week ended Oct. 7, mines produced only 507,000 tons, which is about 49 per cent of capacity. This is a decrease of 15,000 tons under last wek and 35,000 tons under the second preceding week.

Cumulative figures indicate that up to Oct. 7 this field has produced 7,500,000 tons during the calendar year. The potential capacity for that period is placed at 24,117,000 tons, from which it will be seen that only 31.5 per cent of capacity has been produced.

The majority of spot prices on Ohio coals approximate figures set by the state authorities under the emergency legislation, but in some cases are less than the maximum. Eastern Ohio slack is $3.31, nut and slack, $3.31 mine run, $3.56, and various grades of lump, $3.81. Middle District slack is $3.99, mine run, $4.24, lump, $4.49. West Virginia Panhandle coal is being sold at approximately the figures prevailing on eastern Ohio. Very little West Virginia and eastern Kentucky coal is yet coming into this section because of the transportation situation and quotations on these coals are around $6.50 for mine run and $8 for lump.

Bituminous coal receipts at Cleveland during the week ended Oct. 7 were the largest in many months, total receipts amounting to 1,831 cars which is an increase of 560 cars above the quantity received during the preceding week. Industries received 1,548 cars and 283 cars were for retail yards, the increase being almost entirely in steam coal consigned to industries.

Lake coal is being floated faster than it is coming forward. Stocks on hand at the lower docks are decreasing.

BUFFALO

Jobbers are still declaring that it will not be long before the car supply is so small that it will be difficult, if not impossible, to move coal as fast as it is needed. The squeeze so confidently predicted has not arrived on schedule and the bold ones are hoping with no little confidence that the shortage will not be much if any greater than it is at present.

Somehow it is impossible to keep this country from booming, no matter how many snags it strikes. Maybe they are needed to keep us from forgetting how to steer the ship in a storm. We used to think and work in oxcart units, even in the days of plenty of people not so very old. Now we must think in automobile and aeroplane units and do it ahead of even their time or be run over. Maybe we can afford to give the union miner an automobile pay and have some left.

Prices vary as widely as ever. The range is $5@$5.50 for Pittsburgh gas lump, and Allegheny Valley mine run, $3.75@$4.25, with some No. 8 at $4.75 for lump. Slack is not as high as mine run, about $3.25@$3.50.

COLUMBUS

A reaction has taken place and all grades are stronger. Demand for lump is the strongest feature with sales made around $5.50 for Hocking. The regulations of the Ohio Fuel Administration relative to maximum prices are having the effect of driving the lump out of the state. Retailers in all sections are trying to buy stocks as the recent cold spell has forced the consumers into the market.

Retail stocks are almost nothing and the public is apparently waking up to the danger of the situation. Many of the dealers are compelled to buy West Virginia and Kentucky lump at high prices to take care of the demand. Retail prices are showing some declines with Hocking lump selling around $8@$9. West Virginia splints are $10@$10.50, and Pocahontas, when obtainable is higher.

Steam business is not as active, although railroads are taking a large tonnage. The Lake trade is now booming with a large tonnage moving from Ohio mines to the lower ports. Much of this is mine run which is bought around $3.25. Some mine run which is incapable of being screened is selling at slightly less figures.

DETROIT

Receipts are rather more liberal. According to railway figures, 1,396 cars were received in 48 hours ending at midnight, Oct. 11. Average daily requirements, excluding railway coal, are approximately 550 cars.

There is not a very active demand. The greater part of the business is apparently continuing on a hand-to-mouth basis, representing purchases by industrial plants that have exhausted their reserves. Assuming that a reduction of prices is likely to come after the close of the Lake movement, the retailers are striving to guard against being caught with too much coal acquired at present prices. The householder demand represents a makeshift to tide the buyer over to a time when he hopes to find anthracite available.

Smokeless lump and egg is $8.50, mine run, $6.50@$6.75. Hocking lump and egg is $6, mine run, $3.75@$4, nut, pea and slack, $3.25@$3.50. Pittsburgh No. 8, 2-in. lump is $5, mine run, $4@$4.25, slack, $3@$3.75, Fairmont lump is $5, mine run, $4.50@$4.75, slack, $4.50. Kentucky lump and egg is $6@$6.25, mine run, $4.75, slack, $4.50@$4.75.

NORTHERN PANHANDLE

Mines are experiencing difficulty in securing all the cars they need, and in moving coal in the usual channels even after cars are secured. Lines to the Lakes are choked with loads. The fact that so many mines load railroad fuel is helping to maintain an output. Prices are lower all along the line in view of the large volume of coal turned back from the Lakes.

Northwest

Coal Cargoes Up Lakes Not So Numerous Now

Unprecedented Shipments Fill Demand During Past Weeks—Rail Coal Is Arriving Too—Low-Grade Stocks on Hand Worry Dealers.

The tremendous flow of cargo coal up the Lakes gave evidence, at the end of last week, of slacking off considerably and the keen edge of Northwest demand was somewhat blunted so that nobody worried much even though cold weather is arriving and household demand for hard coal is getting brisker with small shipments to satisfy it. In some markets the price of anthracite continues to stick around last year's scale. Since the general advance on smokeless coals a short time ago there have been no further ascents of quotations on any domestic coals.

A fair flow of rail coal continues, some of it crossing Lake Michigan by carferry from the East, some coming up from Illinois and some from the lignite fields of North Dakota. The result is so much coal is here that dealers who stocked lightly on lower-grade fuels during the summer anticipating a worse October condition than prevails, are having trouble unloading.

MILWAUKEE

The coal situation is improving with recent heavy receipts at the docks. There is plenty of soft coal but anthracite is bound to be scarce. But if no rail blockades occur during that season the supply may prevent discomfort. At present anthracite is being sold at the prices current before the strike. Anthracite is moving to the Northwest very freely by rail, carferrying across the lake.

Coal cargoes are coming in faster than at any time this season. Thus far in October seven cargoes of anthracite and thirty-eight cargoes of soft coal have reached the docks, the former aggregating 56,200 tons and the latter 336,316 tons. Cargo receipts since the opening of navigation to date aggregate 56,900 tons of anthracite and 1,627,271 tons of soft coal.

Following is the complete schedule of prices promulgated by the dock companies on Oct. 1:

Anthracite (retail) Egg, $15.75; stove, $16; nut, $15.95; pea, $14; buckwheat, $11.50.

Bituminous (wholesale) Pittsburg, Hocking & Youghiogheny, $9.75; pile run, $9; screenings, $9. West Virginia screened, $10.25; pile run, $9.75; screenings, $9.75. Pocahontas screened, $13.75; mine run, $9.75; screenings, $9.75; smithing, $11.75. Illinois and Indiana screened, $10.25; pile run, $9.75; screenings, $9.75. Coke, large sizes, $16; pea and nut, $13.

MINNEAPOLIS

The wholesale trade is pretty well over its fears of a serious shortage and is now studying the opposite danger of having too much of the high-priced but lower-grade soft coal, which had to be bought when coal first became available. The better coal is now available, and it is a commercial puzzle what to do with the poorer grades on hand.

The fuel distributor has made an announcement that the Northwest is reasonably assured against any serious shortage of soft coal. This has been realized for some time past, since it became apparent that there would be a reasonable functioning of the railroads. It is true that the interior has not been buying heavily. So far movement from docks is some 20 or 25 per cent lower than a year ago.

It is anticipated that prices on both soft coal and hard will average at least $1 a ton higher than a year ago, although no new hard coal has reached these cities, and no new prices have been announced.

The demand for steam coal is limited. Buyers are awaiting lower prices. They may win in their position, for there is accumulating a certain amount which will doubtless have to be offered at reductions.

DULUTH

Official figures just made public confirm reports that there was a heavy falling off in shipments from the docks during September. Only 16,178 cars went out, of which approximately one-third were loaded from Duluth and two-thirds from Superior. Last year 18,735 cars were shipped.

Receipts of bituminous coal during September were gratifying. In all 1,489,000 tons were received as compared with 657,170 during the same month last year, but anthracite receipts were only 10,600 tons as against 182,600 tons in September last year. For the season to Sept. 30, receipts of anthracite aggregated 27,600 tons, as compared with 1,380,000 tons last year, and bituminous receipts were 1,963,800 tons against 7,186,426 tons last year.

Prices on anthracite have been set as the same as during the latter part of 1921. Coal will go from the docks as follows: Stove, $12.90; nut, $12.75; egg, $12.50; pea, $11; buckwheat, $8.50. Anthracite is being allocated by the fuel administrator at St. Paul. The four cargoes which were received this week were sent to North and South Dakota, the Mesaba iron range cities and villages and to Duluth and Superior. Bituminous prices remain firm as last quoted.

Beside the four anthracite cargoes 52 of bituminous arrived here this week. It is thought that this will prove the high water mark in shipments as only 19 vessels are reported on the way.

New England

Steam Demand Still Quiet; Prospects Not Very Bright

Light Industrial Production and Use of Oil and Electricity Make Gaging of Requirements Difficult—Only Scattered Inquiry Expected—British Receipts Wane.

Demand for all grades of steam coal is extremely quiet. Inquiry is restricted to small users, and apparently there is little prospect of any comprehensive business for some weeks to come. The textile and other industries are still on light production and so much tonnage has been replaced by oil and electric power this year that it is more difficult than ever to gage probable requirements.

The trade seems to have settled down into an attitude where every sale is so much to the good, and only scattered inquiry is expected the balance of the year. Receipts of British coals are slowing down.

Pocahontas and New River shippers are sharing the general dullness. Receipts here are somewhat better on contract, due to marked improvement in dispatch at the various rehandling wharves, but spot transactions are very few. Coal at Newport News and Norfolk is not only in plentiful supply but accumulations show a material increase from day to day. The Western market is not proving as strong as anticipated, and that situation is throwing an extra volume to Tidewater.

While cargoes of British coal are still coming in and more are on the way, the harbor congestion is rapidly clearing up. So far as we can learn there are practically no new sales except of tail-ends that the shippers find themselves obliged to dispose of. On these latter the average price has ranged $6.50@$7 delivered alongside, although in a few instances coal has been sold on cars at the same figures. September showed heavy receipts of foreign coal but by the end of October the trade expects to see the last of these cargoes.

For the Pennsylvania grades there continues only mild inquiry. Orders are especially scarce within easy reach of Tidewater where Hampton Roads coals can be had at reasonable prices. More than a few operators represented in this market are obliged to consider shutting down through lack of business at prices that will pay the present wage scale. Some of the mining interests have already set a minimum price, and unless current demand takes a brisk curtailed production is inevitable.

Cincinnati Gateway

Domestic and Smokeless Exceed Gas-Coal Values

Drop in Steam Price Duplicated in Gas and Byproduct Quotations—Competition Expected to Cause Further Reversion—Lake Business Waning—Rail and River Shipping Grows.

Domestic and smokeless fields are the star features in the Cincinnati market just now. They have crowded gas coal from the center of the stage. The precipitous drop that was taken in the price of steam coal a week ago has been followed with a loss in values on the part of gas and by-product. Those who are market wise report that there will be even further recessions because of the pressure of competition that is being brought to bear by other fields thru those marketing through this focal point.

The Lake business continues to dwindle, although there is still a large tonnage headed that way but there are no cargo takers here now and little buying is being done to help along the supplies piling up. Rail and river shipping is a growing feature here with several companies announcing that they intend to expand in this direction.

HIGH-VOLATILE FIELDS

Kanawha

Kanawha mines are still laboring under the handicap of a car shortage which limits working time to two days a week. The market for steam coal is decidedly sluggish. That the price is not lower is of course due to the shortage of cars and the limitation it imposes upon production. Byproduct is in somewhat better demand than steam, and prepared grades, being extremely scarce, are still on a high level. Failure of industrial buyers to place orders is looking for a scarcity of the prepared grades, which is of course augmented by the shortage of cars.

Logan and Thacker

The tonnage in the Logan territory is but little more than a third of normal. Production we are not able to make accurate Lake deliveries and are in general experiencing difficulty in getting coal to their customers in the West which affects the spot market. Buyers are accepting coal in small lots with a view to forcing still lower prices.

The only factor which prevents unsettled conditions in the Kanawha Thacker field is a shortage of cars. Railroad facilities, however, have been somewhat improved. The best market is in the West but prices are undergoing many changes and the general run is on a lower level than Ohio fixed prices. The Lake movement is somewhat better and cars are coming back in larger numbers.

Northeastern Kentucky

Little improvement is to be observed in transportation conditions. Mines are not producing more than 25 per cent of capacity. There is a little freer demand at the Lakes and it is possible to get more coal through. Prices show a downward trend, at least as to steam coal which ranges $4@$4.75. Prepared grades are much higher. Gas coal is in better demand than steam fuel.

LOW-VOLATILE FIELDS

New River and the Gulf

With an inactive market for smokeless in the East, generally speaking, and particularly at Tidewater where coal has accumulated to some extent, a limited production in New River territory almost suffices to take care of the demand for mine run. The limited car supply is having a tendency to check the downward trend of prices. Mine run is commanding as high as $6.50 in certain Western markets.

Gulf mines are not operating more than two days and a half a week owing to poor transportation facilities. There is no probability that there will be any immediate improvement in the situation. Poor transportation facilities make less difference than would be the case if there were a stronger demand in Eastern markets and particularly at Tidewater. Better markets in the West are not helping Gulf producers, however, inasmuch as the railroads are unable to furnish facilities to move coal to such markets. There are more miners in the smokeless fields than there are jobs.

Pocahontas and Tug River

Conditions on the N. & W. appear to be somewhat more conductive to a larger production, but mines are not producing in the aggregate more than half of potential capacity. The bulk of the output is still being forced into Eastern markets owing to the inability of shippers to get much coal through to the West. The Tidewater market is decidedly sluggish.

Although there has been a slight improvement in the Pocahontas region, the reverse is true as to Tug River mines where for a time recently production has been cut to the very quick owing to transportation disabilities, which precluded a large movement to Western markets. Although there is not a particularly brisk market, the demand is still in excess of the supply, since mines are hardly producing enough to take care of contract requirements.

CINCINNATI

The smokeless situation is in rather a bad way because of the scant number of smaller cars to move coal to the inland markets and the endeavor on the part of the larger companies to live up to their contract requirements. What coal there is falling into the hands of the wholesalers is held at prohibitive figures. Little or no screenings are coming through and this makes its price on the basis of the run of mine.

Domestic buyers are flocking to this market in increasing numbers as a natural result of the cold spell. While there are a large number of mines turning to making prepared, as a result of the drop in the price of mine run yet the supplies are still inadequate.

The car supply is still in a horrible shape. Coal River, Cabin Creek and other Kanawha fields that have shipped only a small amount in many months are particularly hard hit, now that they have labor available.

The retail situation is in a cluttered state. Householders, caught with bare cellars when the cold snap came, are clamoring for coal. There is no change in prices.

West

DENVER

Production in Colorado, according to many of the larger operators, is less than 50 per cent of normal, thanks to bad transportation. However, all Colorado points are well taken care of as the supply is delivered by system cars, which are kept within the confines of the state.

All classes of coal are plentiful in supply in Denver with the exception of anthracite. Anthracite production has been stopped in Colorado on account on the car shortage. No changes in prices at the mines have been made since Sept. 1. Lump varies from $6 @$8. Nut is selling $5.50@$7.50, mine run, $4.25@$5.50, slack, $3@$4.50.

KANSAS CITY

The Kansas coal fields are getting better running time than the average of other fields and as a result the market is fairly easy and prices steady. Fuel oil continues a great factor. Some steam plants are still changing over to oil and some are changing back to coal, but on the whole, it would seem that in spite of what the operators have done in the way of reducing prices, oil is gaining. One reason for this is that when the operators made the price $2.50 for slack they had to make the price for domestic grades, lump and nut, $6, and this has caused such general dissatisfaction that there is difficulty in maintaining the $6 level. Much has sold down to $5.50.

SALT LAKE CITY

Business is still quiet. The weather continues summerlike and those who would buy coal for storage purposes are waiting for the findings of the grand jury, which set out a few weeks ago to examine the price-fixing charges preferred against the operators and dealers by a local newspaper. It is being stated that no indictments will be made.

The car shortage is hampering the mines and production has fallen considerably of late. One coal official declared it is now only 45 per cent of capacity. It is estimated that Salt Lake City has but 10,000 tons in its yards now.

News Items From Field and Trade

ALASKA

The Alaska Agricultural College and School of Mines opened at Fairbanks Sept. 18. A large number have made arrangements to enter. Miners all over Alaska wish to take instructions as soon as their working season closes. The school, organized and headed by Charles Ernest Burnett, formerly federal judge in the territory, opens with the largest library in Alaska, made up of gifts by individuals.

CONNECTICUT

The Elm City Coal Co., New Haven, has recently been incorporated to engage in the coal business. The capital stock is $25,000, and the incorporators include: Jacob Rodofsky, M. Y. Lifsher, and A. J. White; all of New Haven.

The Capitol Coal Co., of Hartford, has filed papers of incorporation under the laws of Connecticut to engage in the retail coal business The capital stock is $50,000, and the incorporators are: Jacob Berson; Joseph J. Berson; and Joseph J. Trachtenooth; all of Hartford.

ILLINOIS

The Callaway County Coal Co., which had been operating a strip mine near Carrington, Mo., for nine years, but which was recently dissolved, has sold its machinery and equipment to F. L. Crosby and Lester J. Miller, of Mexico; L. R. Herrick, of Farmer City, Ill., G. L. McCutcheon, of Canton, Ill., and Carter Norris, of Fulton, several former members of the old firm, who will operate a new corporation under the name of the **Cuba Coal Co.** The company has purchased 80 acres of land near Cuba, Ill., which, according to a government survey, has a decided advantage over the old Carrington field. The equipment is now being moved and the company expects to be in operation by the middle of November.

Coal has been found near Mt. Vernon, in Posey County, at a depth of 75 ft. A 30-in. vein was struck at 32 ft., but the thickness of the lower vein is more than 4 ft. The prospecting is being done by **Lawrence & Bratcher**, who have mines in Illinois. Work on the mine proper will be started in a short time.

The Verona Coal Co., Verona, has been incorporated with a capital stock of $15,000. The incorporators are: C. H. Fellingham, Fred Harford, R. J. Glenn, J. P. Handford.

Coal hoisting at the **Litchfield mine**, purchased several weeks ago at receiver's sale by **Harry Tanner**, Pana, will be in progress within a month. The mine has been sunk lower in order to tap a lower vein of coal. The present vein is six feet thick.

INDIANA

A petition for articles of incorporation for the **Chicago, Attica & Southern R.R. Co.**, which will take over and operate the abandoned Chicago & Indiana Ry., known as the Indiana coal road, will be filed with the secretary of state in Indianapolis soon. While the mines in the extreme southern section have been abandoned, the northern part of the line never has been developed. Brick and clay plants are strung along most every section of the line and many plants were threatened with extinction when the old line was abandoned. Charles F. Probst of Chicago and George Barnard, of Indianapolis, attorney and formerly a member of the Indiana public service commission head the corporation. Stock to the amount of $1,000,000 will be issued. The board of directors of the new company are in addition to Mr. Probst and Mr. Barnard, Roland G. Butler, Urbana, Ill., Shannon Nave, Attica, Ind.; Fred Lyons, Brook, Ind.; J. N. Rhode, Pine Village, Ind., and E. Scott Boone, Kingman, Ind.

The Dana Collieries Co. has been formed at Indianapolis for the purpose of mining coal. The company has a capital stock of $100,000 and the organizers are George Hilgemeier, Anna Hilgemeier and William K. Sprouls.

Felix M. McWhirter, president of the Peoples' State Bank in Indianapolis, has been asked by C. E. Spens, government coal distributor, to serve as a member of the advisory committee for handling the coal distribution problem in Indiana by keeping in touch with the Indiana fuel situation and informing the federal fuel administration of the needs of industry.

Mayor Shank of Indianapolis, has named five citizens to serve as a committee to work with the fuel administration in regulating distribution and prices of coal. Among the five named, two are out of the city, two have declined and one has accepted. **Arthur E. Bradshaw**, president of the Allied Coal & Material Co., has announced he will serve on the committee. The mayor has announced he will appoint others who will serve on the committee.

A consolidation is taking place between the **Indiana Bituminous Coal Operators' Association**, which is the old line labor organization of shaft mine owners, and the **Indiana Coal Producers' Association**, of strip mine men. The question of representation in Indiana on the new reorganization Committee of the joint operators' and miners' conference is now easily disposed of. The state gets two representatives, but since the strip association fuses with the main association, there is nothing in the way of giving the Brazil Block region one of the two memberships. The state will in reality have three seats because Phil. Penna, permanent chairman of the joint conference, is a member ex-officio.

KENTUCKY

In western Kentucky when strikes tied up other fields, miners made so much money that roads were full of miners who were traveling to their work in automobiles. Negro miners were always willing to buy a big car. Used cars were bringing 40 per cent more in the coal fields than in the cities. Today the coal car shortage is so severe that it is hard for miners to keep up even a "Liz" on surplus earnings. Reports of actual starvation conditions among miners of Tennessee and Kentucky fields have been made by the district office of the United Mine Workers at Knoxville, Tenn. Miners have been working but one day a week.

R. H. McCormack of Cincinnati **E. McConnaughy** of Dayton, and **C. H. Carson** of Kalamazoo, all of the Kearns Coal Co., were visitors at the Dudley and Marian mines in the Hazard district recently.

Earle B. Heffner, who was chief engineer for McKinney Steel Co. for the past five years and more, has severed his connection with the above concern. Mr. Heffner and associates have formed the **Heffner Elkhorn Coal Co.**, having 200 acres of coal on Marrowbone. This company plans on opening up this tract at the earliest possible moment and installing an up-to-date mine in all respects.

The Acosta Mining Co. has been formed by W. H. Cottingham, W. C. Burch and Ed. Purcifful.

The Smith-Alston Coal Co. has been capitalized at Hamlin Ky. for $20,000 and incorporation papers have been filed. The incorporators are M. V. Alston, G. B. Smith and G. R. Alston.

MISSOURI

The Carter Coal Co., of Wellington, has been incorporated with a capital stock of $60,000 and will promote and conduct a coal mine as well as a mercantile establishment in connection with it. The incorporators are Fred D. Flocke, Charles G. Grumbo, August Alsing, Herman H. Limtong, H. G. Wille, Edward H. Kuhlman, Henry G. Drewel and Adolph H. Kuhlman.

MONTANA

At a meeting held late in September, in Butte, [illegible] miners, decided to form a union of their own to be in a position to treat with operators when necessary. Nothing was said about wages, leaving the impression that the men were satisfied with the present rates for the present.

Albert Griffin has severed his connection with the Keene Mine, Bair-Collins Coal Co., Roundup. Mr. Griffin was superintendent.

NEW YORK

In order to give greater attention to C-H business in western New York and Ontario, a branch office has been opened by the **Cutler Hammer Mfg. Co.** This office is located in Buffalo. B. A. Hansen, formerly located in New York, has been placed in charge.

J. B. Clark, Jr. has recently become associated with the Pennsylvania Crusher Co. as sales engineer, and will make his headquarters at the company's New York office. For a number of years, Mr. Clark has been associated with the Koppers Company of Pittsburgh in the erection and operation of byproduct coke plants, including the Seaboard plant at Jersey City.

Grant B. McLaughlin & Co., on Oct. 1 opened a coal office at 713 Mutual Life Bldg., Buffalo. Mr. McLaughlin was formerly connected with the Donner Steel Co. and will also look after the iron trade.

OHIO

C. A. Clyborne, president of the Three States Coal Co., with headquarters at Bluefield, was a recent visitor to the Cincinnati office of his company.

For the third time, the **Columbus Board of Education** has asked for bids for approximately 10,000 tons of lump coal for the winter fuel supply. The last date for opening bids has been fixed at Oct 23. On former occasions all of the bids were rejected.

Quite a few coal companies, mostly for mining and distribution purposes, have been chartered recently under the laws of Ohio. Among the number are: **Windsor Coal Co.**, Steubenville, capital, $25,000, to mine in Jefferson County, incorporators Harry A. Bell, Thomas Rock, Bates Williams, A. Barakat and S. S. Hill. **The Maghes Coal Co.**, of Byesville, capital $25,000, by Aaron J. Maghes, Samuel Barnicker, Jacob Weiner, James W. Bell and E. M. Johnston. **The Atlas Coal Co.**, Cleveland, capital, $10,000, by P. J. Van Dame, Samuel Horowitz, A. Lukowitz, M. Mergner and E. R. Walters. **The Cottage Grove Coal Co.**, of Akron, capital, $75,000, by Nathan M. Berk, S. Bernard Berk, Katherine Wyss, Ross Darling and George W. Coble.

PENNSYLVANIA

A State charter was granted at Harrisburg recently to the **Chestnut Hill Coal Co.** Pottsville. It has a capital stock of $[illegible],000, and David L. Griffiths, Pottsville, is treasurer. The purpose is mining and preparing coal for the market and the incorporators are David L. Griffiths, Ralph M. Griffiths and Albert Morgan, all of Pottsville.

The Shaffer Coal Co., Ohiopyle, has been incorporated with a capital of $25,000, H. P. Shaffer, Terra Alta, W. Va., is treasurer, and one of the incorporators, the others being H. C. Shaffer, Cumberland, Md., and C. A. Lambert, Ohiopyle.

The Delaware Lackawanna & Western R.R. Co. has appealed from the assessment of anthracite tax by Auditor General Snyder, and S. L. was for two months producing of coal in 1921. The appeal raises questions whether the revaluations should stand and whether coal used by the companies in producing coal should be taxed. The tax involved amounts to $[illegible]. The latter four months of 1921 are covered by the **Glen Alden Coal Co.** appeals.

A charter has been issued to the **Fair Coal Co.**, Scranton, with a capital stock of $25,000, N. R. Brown, Scranton, is treasurer. Incorporators are: N. R. Brown, Thomas Harrington, Scranton, and Joseph P. O'Donnell, Kingston.

TEXAS

John Williams, president of District 21, United Mine Workers, has been removed by Sam Mahon, [illegible] international president, following [illegible] of treatment of coal miners in the central western Texas coal fields about Thurber. Miners and other units in Texas Rangers sent into the district. It is alleged they have intimidated, threatened and otherwise attempted to prevent striking coal miners to go to work. Mr. Wilkinson has also telegraphed Attorney General Daugherty regarding the situation and has requested an investigation by the Federal Government. The miners have been on strike for about a year and a half.

VIRGINIA

The Elmwood Coal Corporation, Gilmanton, has been organized and incorporated with James W. Daniel as president and [illegible] as secretary. The authorized capitalization is $50,000.

The Brooke Coal Co. has been incorporated with $50,000 capital stock to [illegible] coal and timber in Brooke County. The incorporators are [illegible] and L. H. Sargent is president. [illegible]

WEST VIRGINIA

Claiming that the U. M. W. have refused to sign the agreement with him and that he is bound to pay the penalty for non-performance of the contract, H. M. Sage is [illegible] operators' association. The union has charged the operator with non-payment of the check-off for the month of August. The operator claims that the check-off was paid to the Charleston and Kanawha Coal Co., and that this company refused to turn over the money to the union. The operator claims that the check-off was paid to the Charleston and Kanawha Coal Co. by agreement with him until the Federal court decision was rendered, and that this company refused to turn over the money on the closed shop plea. The case is to be heard in the district court of the Southern District of West Virginia. Officials of the International Union and local officers of the United Mine Workers of America are named as defendants. Sage has also instituted attachment proceedings with a view to obtaining the payment of money withheld by the check-off throughout Harrison County. Many of the mines have been closed for a number of days and it is understood by other companies.

The Blue Ridge Collieries Co., a Virginia [illegible] has been granted a West Virginia charter. Capital is 15,000 shares of no par value stock.

Vice President W. G. Paik of the Kanawha Coal Co. at Charleston, was a recent visitor to Bluefield.

Organization of the **Slater Creek Coal Co.** in Charleston coal field presages development work on the affairs owned on a fairly large scale, the company being capitalized at $[illegible]. Its offices will be at Charleston, having an active part in the organization are: A. S. Guthrie, E. H. McNeil, W. P. Hoff, A. J. Peck and L. S. Carter, all of Charleston.

The Cedar Grove section of Kanawha County is to be the seat of operations of **the Cedar Grove Coal Co.**, of Danville, Boone County, which is capitalized at $[illegible]. Associated with J. J. McLaughlin of Danville in this concern are: Horace S. Meldrum, Paul Smith, Louise Theiling and Libbie Walker, all of Charleston.

BRITISH COLUMBIA

Consideration of the coal mining returns for the past few months indicates that some records have been made in production. **The Western Fuel Corporation** of Canada during August had an output of [illegible] tons. As far as is known this is the greatest monthly output to the credit of the company since it began coal mining. The average production for a month is [illegible] tons. **The Canadian Collieries, (Dunsmuir) Ltd.**, also has improved its showing remarkably, production for August being [illegible] tons. **The Nanoose Wellington Collieries** had a production in August of 13,312 tons the best record yet hung up by this corporation. The same activity prevails in the Nicola-Princeton coalfield. **The Coalmont Collieries**, for instance, jumped their production to 18,059 tons. This is the highest mark reached by that concern. **The Middlesboro Collieries**, too, had an output of 9,500 tons, which compares more than favorably with past showings. Total production of the Provinces for this year to date approximates 1,600 tons which is an exceptionally fine record when it is remembered that the collieries of the Crow's Nest were closed down through strike from the latter part of March to August 28 last.

NOVA SCOTIA

The Gore Coal Co. has announced the discovery of a new seam of coal at a depth of more than [illegible] ft. This is the second seam located through drilling operations at Gore, and it is expected that shafts will be sunk shortly.

ONTARIO

The British American Coal & Ice Co., Ltd., of Ford City, has been incorporated with $40,000 capital stock. The provisional directors are Morris Shapiro, Arthur Stewart and Israel B. Levin.

York Coal Co., Ltd., of Toronto, has been incorporated with $100,000 capital stock. The provisional directors are James Franceschini, Harry H. Salmon and David F. Brazel.

WASHINGTON D. C.

The United States Civil Service Commission states that there is urgent need for eligibles to fill positions of junior engineer and deck officer under the United States Coast and Geodetic Survey, and that an examination for such positions will be held on Dec. 13-14, 1922. A prerequisite for consideration is that applicants shall have completed at least three and one-half years of a course in civil engineering leading to the degree of B.S. or C.E., in a college, university, or technical school of recognized standing. Graduation with one of these degrees is required before appointment.

Traffic News

[illegible] shipments of coal from the Kanawha and Cincinnati fields as well as any shipments from the Tri-State field, are said to be primarily responsible for the embargo [illegible] Coal Railroad will be in a position to handle [illegible] shipments is made evident by the announcement that the company has given orders for 3 new [illegible] cars. The coal carrier, however, will be well under way for the winter before these cars can be delivered.

Daily and weekly reports on freight car supply and distribution of all railroads [illegible] in Washington have been requested by the Department of Justice. The reports are to cover the [illegible] work of the railroads and are [illegible] to view of the present shortage of freight cars. The roads included are the Milwaukee, Great Northern, Northern Pacific, Chicago-Washington Harbor, Portland & Seattle, Grand Trunk Western & Canada, Canada Pacific and Toledo [illegible] Railroads.

In order to facilitate the handling of coal on the **Pennsylvania Railroad** orders have been issued for the [illegible] to [illegible] cars [illegible] Tuesday [illegible] cars [illegible] of the [illegible] of cars to [illegible] Information of the Interstate Trade Commission. COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, Editor

Volume 22 NEW YORK, THURSDAY, OCTOBER 26, 1922 Number 17

When and Where to Apply Self-Restraint

WHAT a lesson the public is teaching itself on coal! A most remarkable demonstration of the great axiom that the destiny of the coal trade is in the hands of the consumer is being staged. There have been buyers' strikes on coal before but never under the conditions of today. Previous general withdrawals of consumers from the market, to the discomfiture of the coal producer, have always had a background of large stocks and were explainable as the normal result of falling prices on an overstocked market. They have always gone too far, it is true, and reacted in the end to the disadvantage of the buyer. Hitherto these long sweeps have had no guidance; they have simply been the expression of uninformed mass psychology.

Six years ago this week the country awoke to the realization that consumers' stocks were low, consumption was increasing and that a nationwide car shortage had developed. Prices at once reacted to new high levels. The coal shortage then begun lasted until the armistice. Conditions with respect to stocks, consumption and car supply are essentially the same today as in the autumn of 1916. The differences are only in degree; the relative positions are the same. Yet the price is falling.

The United States Chamber of Commerce has just completed a survey of the country and reports that although reserves of soft coal are "less than normally carried," the bituminous-coal situation "is becoming easier" and that there is no "general complaint as to price." Production of bituminous coal is no more than sufficient for current consumption and permits no stocking. "It should be borne in mind, however," says the Chamber, "that this is an average figure [of stocks] of small plants and large plants, and covers stocks varying from a few days' to two or three months' and in some instances even longer."

The self-restraint of the buyer is being intelligently directed. The mine price of soft coal is even yet high enough to call forth all the production the railroads can carry. The buyers are taking all the coal they can possibly get, but they are buying it without panic. From the standpoint of supply and requirements—as contrasted with demand—this is a sellers' market. Yet the buyer is so largely in control that he is really making the price on a large part of the output.

In 1919 the positions were reversed. The country was overstocked with coal, consumption was falling sharply. The coal producers, fresh from the lessons of the war, having been forced by the Fuel Administration to learn their costs, refused to be stampeded into price cutting. It was a buyers' market in the summer of 1919, if ever there was one, but the price was maintained by the self-restraint of the seller.

If it be granted that steady prices and absence of violent fluctuations in the market make for stabilization of the coal industry, then the obvious conclusion is that self-restraint should be preached to and practiced by the side that will be benefited thereby. Teach the public its responsibility in a two-sided game, as well as the coal operator. It is easier and more sensible to drive home to the buyer his selfish interest in not going wild and paying prices for coal that cannot encourage production and thus to prevent high-price scandals, and to give the operator the right and opportunity to protect himself against the ruinous low prices that obtain at other times, than to campaign against the natural and human instinct of the buyer to beat the price to the lowest level irrespective of consequences, or of the producer to refuse to take a handsome profit when it is offered to him.

The present concerted restraint of the coal buyer is not an accident. It is the result of broad national planning, conceived in advance of the fact. It exhibits a phase of the national coal situation that we trust will not be overlooked by the Federal Coal Commission in its study. It is true that the chapter is but opening, that the experiment may fail, but it is certain that future chroniclers of the coal question will look back on the buyers' strike of 1922 as a well-conceived stroke of national policy, carefully executed, and that credit for its conception and execution will be placed where it belongs.

Solving Hard Coal's Commercial Problem

COMMERCIAL production of large sizes of anthracite, including pea, averages around 50,000,000 gross tons per year. Of this, in normal years, the railroads take about 2,500,000 tons; gas plants, 700,000 tons, mainly the egg and broken sizes, and industrials some 1,800,000 tons, a total of 5,000,000 tons, or about 10 per cent of the prepared sizes. This represents a substantial and desirable trade.

It was generally recognized during the war that household use should have preference in distribution of the larger sizes and the allotments of the Fuel Administration to other than domestic consumers were cut as much as possible. The allowance for railroad use, for instance, was but half the normal taken for that purpose. Somewhat the same situation has arisen this autumn. With retail distribution of the favored sizes largely on a hand-to-mouth basis and consumers' reserves at a low point, hard-coal shippers are holding back other consumers and discriminating in favor of the small user.

A small industrial consumer of egg coal recently called on the president of an anthracite producing company to inquire as to the prospect of getting 200 tons, his winter's requirements. He was told that he had not the slightest chance, that he was "out of luck," that in fact he "had his nerve" to come in and raise the question. The buyer mildly stated that he well knew that he was a "non-essential" but that during the war

he managed to get his coal and wondered whether matters were now so bad that he could get none.

He was not only given no encouragement but was sent away with the feeling that there was no hope for him in the future. He at once set about installing coal-burning equipment in his plant. Thus a small piece of hard-coal trade was lost. There was no effort to convert him to the use of sizes smaller than pea, although at that moment the steam sizes were in oversupply. This coal-company official might have taken an interest in the fuel problem of this anthracite consumer, called in his engineer—if he chance he has one—looked over the plant, advised on proper equipment for utilizing junior sizes and thus saved an outlet for a part of his product that even in the best times is difficult to move.

Attention to small details is the foundation of successful enterprise. If this incident, involving one of the largest anthracite producing companies and one of the smallest consumers, is typical, and it seems almost to be, then progress in solving the real commercial problem in hard coal—the steam size—is certain to be slow.

Today and Yesterday

NEW occasions bring new duties, and the mining engineer should be as cognizant of this as anyone. A great change has come over the mining industry in recent years. A few years ago the need for exploration dominated every other need. Every mining man in the coal regions of Pennsylvania and later of West Virginia and Kentucky was a geologist, and the residents of those sections were hardly, if at all, behind. Every farmer had coal land to sell, every lawyer and real estate man (they did not then term them realtors) had coal land to lease or dispose of, and every merchant had in mind taking options on coal land or already had it cornered and for sale. The mining engineer's intensive study of geology, consequently, not only solved every-day problems but gave him a standing in the community that he could capitalize.

The day of exploration is largely past. A little of the earlier interest and need for coal geology remains and will always remain. There are still outcrops to be traced and drillholes to be bored; there are still a few unexplored areas in the more important fields; there are still possible extensions of old fields; there are waste and faults, but these matters do not stand where they once did as the leading problems of the engineer. It is a day not so much of exploration of doubtful, as of development of known, deposits.

In mining today we are no longer satisfied to use the natural forces of nature assisted by mechanical appliances. The study of mechanical engineering therefore is the greatest need of the mining man. He no longer can satisfy himself with geodetics, with the geology of the coal measures, the chemistry of mine gases, the physics of air and heat, as was once his wont. He has now to delve and delve deeply into electricity; he has to attain a mechanical mind. He cannot safely let the industry move away from him.

For a while he may be able to regard his mechanical brother as a man in an inferior branch of the service and "make away with it." Or again, for a season he can hide his ignorance of electricity by relying on the advice and place of the salesman of an electrical house. But let him not deceive himself; he cannot do it forever. Let him study now when he has the opportunity; let him ask questions today, when ignorance of electrical lore is still regarded with tolerance; let him gain experience while the chance offers, or the time will come when so much has to be learned that a busy man cannot hope to acquire it and when his mind, no longer as retentive and flexible as in early years, will fail to grasp what is presented to it. The coming executive is going to be well booked on electrical methods. Are you hoping to become an executive or are you expecting to continue in that position? You cannot do it if indifference to such matters prevents you from studying electrical methods.

How Nicely They Do It

A PAPER from DuBois, Pa., contains the heading "Road Work Suffers as Back-to-Mine Move Grows" and describes how the men are leaving their labor on the high roads to work at the mines. The road contractors, if they ever give a passing thought to the irregular way in which their industry functions, need not worry about their men being idle in the winter. The mines will take care of them at good pay, which is about three times as large as the contractors on road work are offering.

The reason why the employees of road contractors do not have an idle season is that they are willing to work at low wages and so can readily drift from one kind of a job to another. If the coal mines paid $2.80 a day to their men they would be deserted in slack periods, and the miner, finding work elsewhere, would make no complaint about the layoff. But because he gets about $8 a day he can find no place to go where he can do as well. He is therefore disposed to stay, working part time at the larger sum and making as much as if he worked steadily at the smaller. Thus he continues his residence around the mines and finds fault with the operator if for several days each week the working whistle is not blown.

If wages dropped at mine workings to $2.80 per day the last would be heard about the overmanning of the industry. Why is it overmanned? Because it pays best, because it is desirable work—cool in summer, warm in winter—also because, unlike most rough work, it is reasonably steady. Most roustabouts have to spend several evenings each month hunting for jobs. They are laid off for every rain and sometimes do not have a chance to return to work till the roads dry. They do well to average an even 200 days a year and then only by eternal watchfulness for odd jobs.

The mine appears to them to be a good opportunity for reasonably steady labor at a high rate. With the present pay the men cannot be driven away from the mines, but should it fall to road-making levels it would be easy enough to wash one's hands of one's men. They would be gone within a day after the work stopped, for then any other job would be at least as remunerative even if not as reliable or as easy as coal mining. The mine workers are always protesting to the public of their hardships, their great hardships—low pay, bad working conditions, irregular work, powder charges, house rent, doctor and hospital check-offs—but the overmanning of the industry proves that they stay, that once they have joined the coal-digging confraternity they will not leave the mines. By this sign they surely make a more conclusive answer to their allegations than anything the operators can say.

Detection of Waste of Time And Current at An Anthracite Colliery

By D. C. Ashmead*
Kingston, Pa.

Few Know Just How Many Hours Their Breaker or Tipple Runs—John Conlon Colliery Measures Idle Time with a Recorder—Also Checks Current Used by Hoists—Care in Detecting Grounds

NEAR the city of Wilkes-Barre is the independent colliery of John Conlon with an output of about 300 tons a day. It is supervised directly by members of the Conlon family with a supervision probably more careful and competent than is customary with a mine of such an output.

The Conlons have long recognized that one of the greatest sources of loss in operation arises from broken time during working hours. Delays in one section of the operation often tie up the whole plant, for nearly all the plant operations are dependent, not only ultimately but almost immediately, on one another. Without storage provision division of labor inevitably produces great loss of time and in mining operations each department must do its work with unerring schedule or almost all other departments will be obliged to wait for the slow department to come up to the mark, thus entailing considerable monetary loss.

Frequently the length of time wasted is far greater than is recognized. Delays are vexatious and we rather like to minimize them when estimating their importance. Because their length is rarely a matter of record, few steps are taken to reduce their number and duration. Hoists are not used to their full capacity, locomotives stand idle, breakers fail to operate. Everywhere are men and machinery on the job yet without doing work of value, adding to the payroll but not to the product.

To detect the wasted time in their collieries the Conlons purchased a number of Servis Recorders. The interior of one of these simple recorders is shown in Fig. 2. The recorder consists in part of a clock to which is attached a recording chart. This paper is graduated to show 10-minute periods. In the other half of the recorder is a pendulum to which a pencil is attached. The recorder is hung vertically, so that the

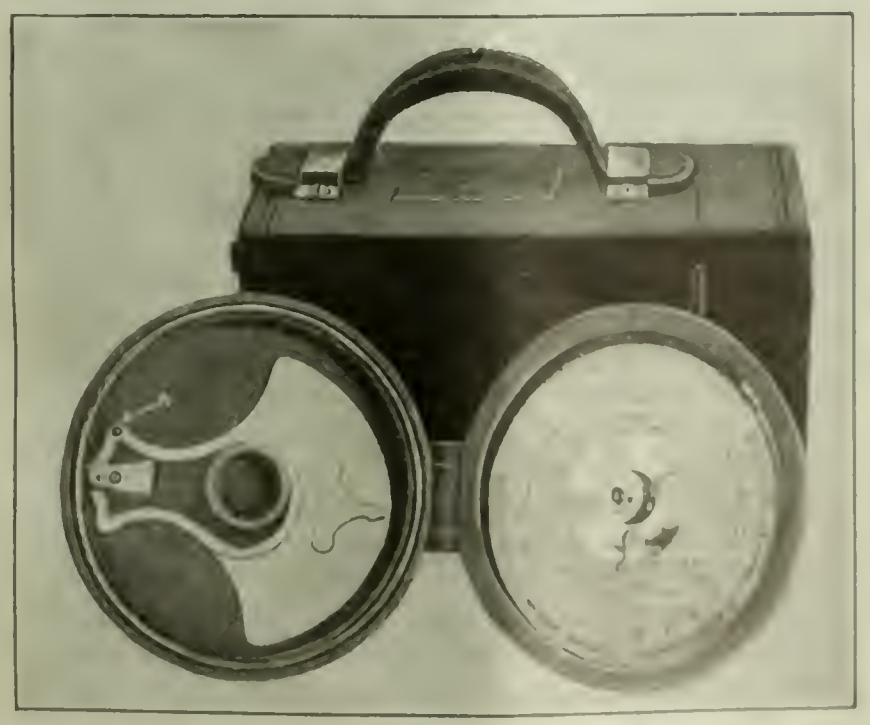

FIG. 1—RECORDER NOTES WHEN PLANT WORKS

Illustration is of interior of instrument. The right half is a paper chart which is revolved by clockwork. It rotates once in 24 hours. On the left is a pendulum in the form of a half disk and shown turned on one side. When the recorder is properly hung, the pendulum swings with the vibration of the breaker or mechanism to which it is attached. A pencil *A*, makes a mark on the chart whenever vibrations are to be recorded.

FIG. 2—CHART SHOWING WHEN BREAKER WORKED

From this chart the actual time of any delay and its length can be ascertained. When inquiries are to be made into causes for idleness, the story is already half told. After knowing the time is known the reason can be found and the cause determined. What suggests why, and why explains how the trouble can be avoided

*Anthracite Field Editor, *Coal Age*.

NOTE—Headpiece shows the John Conlon Colliery, near Wilkes-Barre, Pa. This is a long established, independent operation with offices at Hudson, Pa. About 100 men are employed.

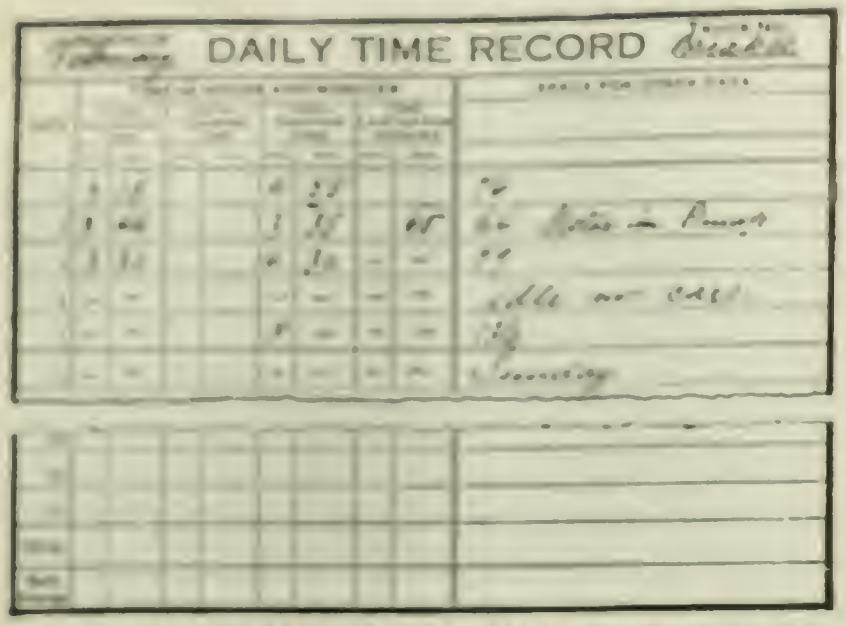

FIG. 3—TIME RECORD MADE FROM RECORDER CHART

pendulum swings free). The case is then closed and locked. As the machinery of the breaker on which the recorder rests vibrates the pendulum swings, making with each swing a mark on the recording dial. When there is no movement because the machinery or the breaker is idle no mark appears on the dial. In consequence the exact time during which the machinery is working is registered on the revolving platen. Every day these dials are collected and the time of full operation or its converse, the time of idleness, is measured.

Not only is the full time of operation shown but each stop also, and it is possible therefore to check up the entire operation of the breaker or motor by inquiring into the reasons for the particular shutdown. Finding out the causes of delay, some rearrangements may be made that will make such delays unnecessary in the future. Just the manner in which the records of this meter are made and used is shown in Figs. 2, 3 and 4. The first shows the actual performance of the breaker in one of its regular runs, the second shows how the results are tabulated day by day and the third expresses by means of a curve the operation of the breaker. By comparing the hours worked by the breaker and the number of cars hauled each day it is easy to determine if the breaker when working is at all times equally efficient.

So much for saving of time; now for savings of current. Two men employed to do the same work under precisely the same conditions will do it with entirely different expenditures of current. One man will be more efficient than another, and even where the efficiency of the least efficient has hitherto satisfied the management and is above the average, comparisons enable the

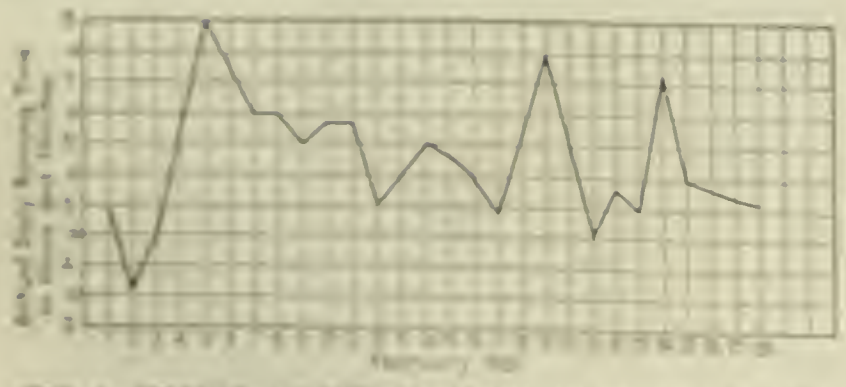

FIG. 4—RECORD OF HOISTING TIME IN FEBRUARY, 1911

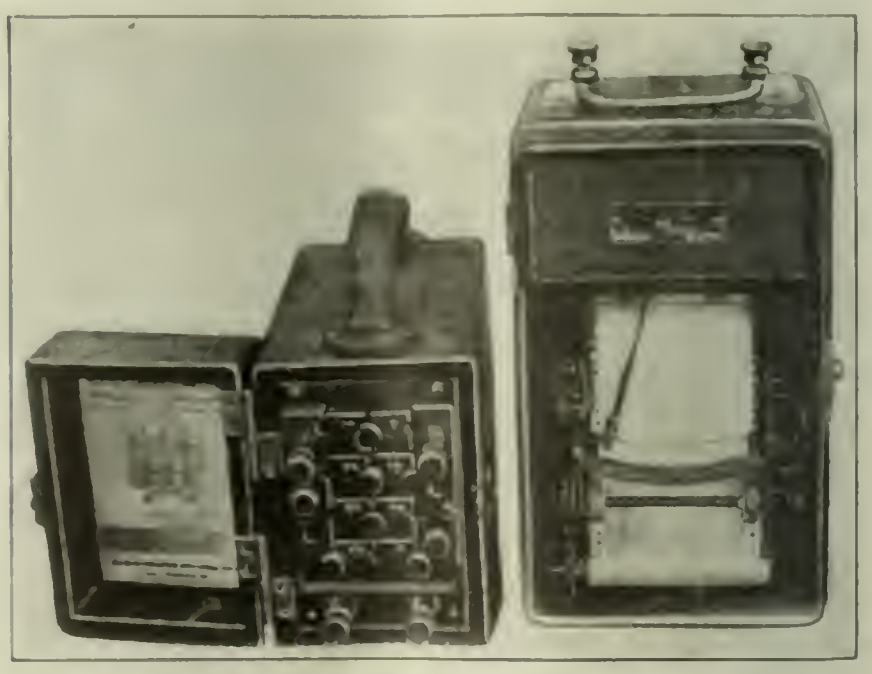
officials and the man himself to see how his efficiency can be raised.

At this mine a hoist is installed which raises the coal through a short slope up a plane to the top of the breaker (headpiece). It was decided that the efficiency of the men operating the hoist should be tested. A Westinghouse graphic meter (Fig. 5), showing the current used, was hooked to the line. This was done without the engineer being informed. From the two charts thus obtained, parts of which are shown in this article, one engineer can be seen to be considerably more efficient than the other. In the first chart the engineer is shown to have used at times as much as 240 amperes and withal did not bring his loads as rapidly to the surface. It is evident that he threw the controller fully on when starting. On the other the other engineer used barely 160 amperes as a maximum and in most cases less than 144 amperes, and yet his hoisting time was shorter.

From these diagrams it can be readily deduced, therefore, that one engineer got out more coal with less



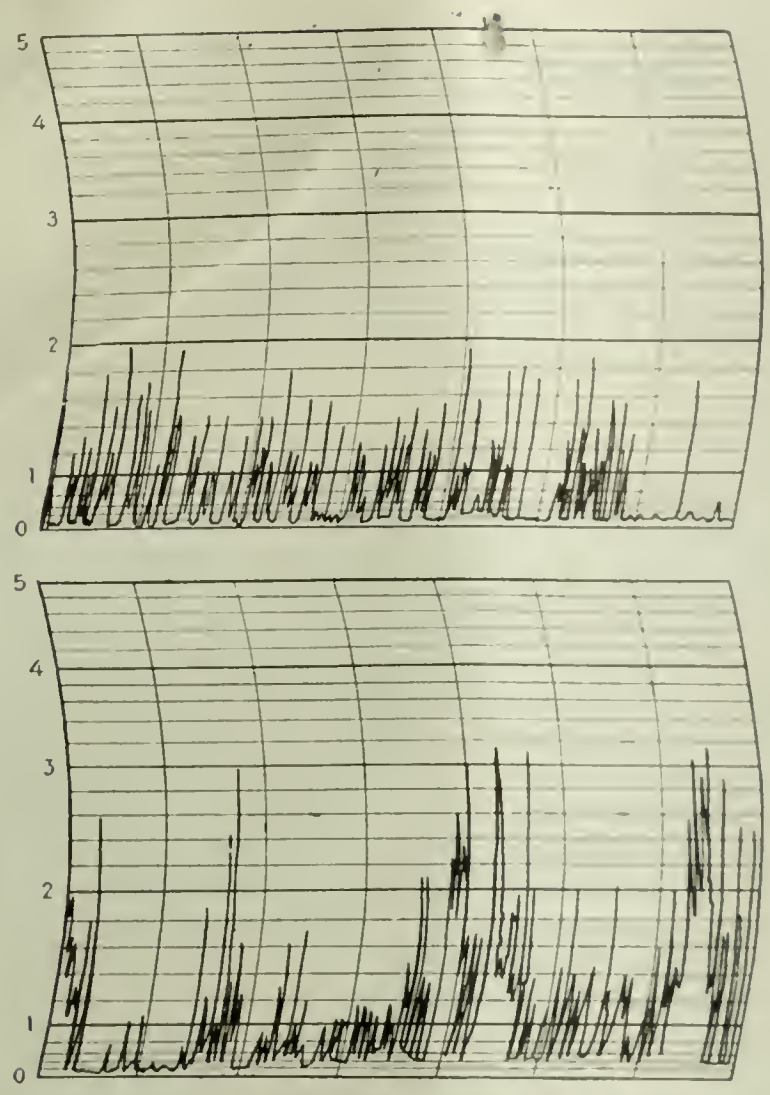


FIG. 5—GRAPHIC METER AND CONNECTIONS

This apparatus was used to ascertain how much power was being used to haul a car up the plane to the top of the breaker and how quickly the work was done.

power and in less time than the second engineer. Evidently with proper instruction the less efficient man could learn to do his work as well as the other man; if not he could be given work where his lack of co-operation or skill would not so greatly injure the company.

The use of electric power without the performance of work is one of the most unnecessary wastes of power around a mine. This type of waste is caused by short-circuits and grounding. At the Conlon Colliery much care is taken to prevent loss of power due to grounding, and for this the simple device illustrated diagrammatically in Fig. 8 is shown. A bank of four lamps (shown also in Fig. 9) connected in series is placed above the switchboard. Lamp No. 1 is connected to wire No. 1 from the transformer and lamp No. 4 with wire No. 3. A connection is made from the ground to a Westinghouse voltage relay. Another terminal of this relay is connected to a point between lamps Nos. 2 and 3. The other two terminals are connected with the leads to wires Nos. 1 and 3. One of these connections is in series with the no-voltage release coil on the main switchboard.

If there are no grounds on any of the lines, then the voltage of the ground lead is 186 volts. An increase

FIGS. 6 AND 7—RECORDS OF TWO MEN HOISTING SIMILAR LOADS ON INCLINE

The engineer whose power consumption was recorded in the upper chart, Fig. 6, used little power and, as can be seen by the frequency and regularity of his peaks, made more runs per hour. The second man was a current waster and did not land as many trips as the first man. He evidently needed instruction.

of potential of 4 volts in this ground will open the contacts on the relay and release the circuit breaker, on whichever line it happens to be.

In case of a ground in line No. 1, lamps Nos. 1 and 2 will light up; if in line No. 3, lamps Nos. 3 and 4 will light up, but if the ground is in line No. 2 all the lamps will burn brightly, in all cases increasing the voltage, which when normal is at 186. When the voltage rises

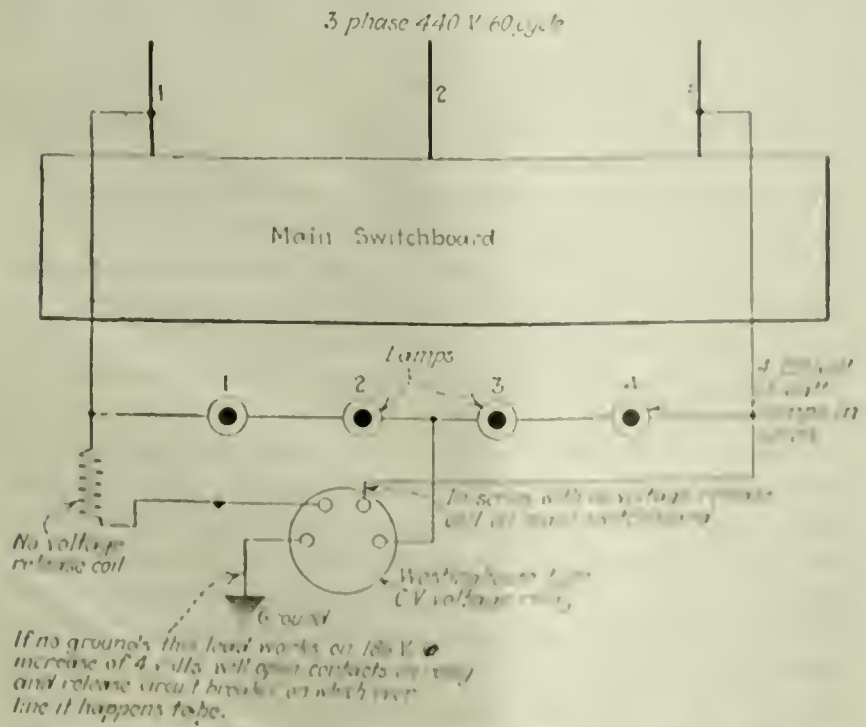

FIG. 8—ADJUNCT TO SWITCHBOARD LOCATES LEAKS

Short-circuits and grounding cause many current losses, preventing the power being used for useful purposes. To this device the Canton colliery gives much credit for lowering the cost of current to 9c. per ton.

in the ground above 186, the relay will open, breaking the circuit in the series coil on the circuit breakers and opening the circuit.

Having a system of this kind it is possible to detect instantly whether there is a ground in any of the circuits. Knowing this the electrician can locate the leak and make the needed repairs. It also tells him when the repairs have been made satisfactorily. When the lines have no grounds the lamps burn with a dull-red light.

By being able instantly to detect losses due to grounds and to ascertain what power is lost in electric machinery by inefficient operation this company has been able to keep its power bill down to about 9c. per ton of coal mined. No steam is produced at this mine. All the power is electric, and therefore with the proper testing apparatus and a man who understands its proper use large savings have been made. There are many

FIG. 9—WIRING OF LEAKAGE DETECTOR

In case of a ground in line No. 1, lamps Nos. 1 and 2 will light up. If one occurs in line No. 3, lamps Nos. 3 and 4 will light up but if the ground is in No. 2, all the lamps will burn brightly, in all cases increasing the voltage which, when normal, is at 186. When the voltage rises in the ground above 186 the relay will open, breaking the circuit in the series coil which forms part of the circuit breaker and opening the circuit

operations in the anthracite region which show a power cost running many times the figure given here, for anthracite unfortunately cannot be mined with as small a power consumption as most of the bituminous coal of this country.

STUDY OF THE PHENOMENA of coal-dust explosions has been continued by the U. S. Bureau of Mines during the present year in a specially designed steel laboratory gallery. This gallery is 10 in. in diameter and 14 ft. long, and is provided with a breeching that has a small cannon and relief valves. Dust under test is injected into the gallery at points spaced 1 ft. apart throughout the length of the gallery and compressed air is used for projecting the dust. A study was made of the interval between the time of projecting the dust and firing the cannon and the influence of the temperature and humidity of the air within and surrounding the gallery was determined. More than 200 tests have been conducted with standard Pittsburgh coal dust, in a part of which inert shale dust was used to limit or prevent the propagation of flame. The gallery has been equipped with the necessary pipes and meters to admit of the use of natural gas for the study of the influence of low percentages of gas on the explosibility of coal dusts. A number of dust samples from industrial plants and from coal mines have been tested in the gallery in connection with explosive hazard reports made by field engineers of the bureau.

Problems of Bituminous Coal Washing and Measures Now Being Taken for Their Solution*

Review of Washery Methods—Trouble with Wet Coal in Byproduct Coking—Why Wash Fine Coal?—Preferably Screen It Out, Wash the Coarse and Mix Washed Coal with Unwashed Fines

BY G. R. DELAMATER
Harrisburg, Pa.

IN THE last three or four years only a very few coal washeries have been constructed in the United States and it is not difficult to find the reason for this fact. During the past twenty years many washeries have been built employing the wet process with a wide variation in the method of its application. It would seem that a marked prejudice against this process in general is now held by practically all who are engaged in the mining and preparation of bituminous coal.

Until about ten years ago the jig in various forms was almost the only type of concentrator employed in the washing of bituminous coal. An exception was the Campbell bumping table, which has been installed in several of the largest washeries in the country. That the results obtained were quite satisfactory in many instances is proved by the recent construction of a second plant for the Cambria Steel Co. at Johnstown, Pa., which is one of the few washeries built in the last four years. Some effort has been made to introduce trough and log washers, but these proved unsatisfactory and attracted but scant attention.

Wet concentrating tables of various types, although extensively employed in ore-dressing plants, had never been used in this country for the preparation of coal, as it was quite generally felt that their capacity, considering the cost involved, made them impracticable for such use. Furthermore, their employment in ore concentration was confined to the small-mesh material, jigging of the larger sizes being the usual practice. No doubt this custom in a field generally conceded to be well advanced in the art of concentration had the effect of fixing the concentrating table in the minds of coal men as being unsuitable for treatment of the coarser sizes.

STAG CANON FUEL CO. INTRODUCES WET TABLES

The Stag Canon Fuel Co. of Dawson, N. M., probably was the first firm to attempt development of a wet table for the concentration of coal, both small-mesh material and some of the larger sizes. The results obtained attracted the attention of manufacturers of wet concentration tables and resulted in the development of several good types suitable for coal treatment.

Possibly the next development of importance was the introduction of the Dorr thickener to replace the old drag-conveyer sludge-tank equipment used as the first step in the reclamation of the washed coal from the water. Closely following this came the introduction almost simultaneously of the Wendell and the Elmore centrifugal continuous coal driers.

Rapid replacement of the beehive by the byproduct coke oven imposed an even greater need for improvement in coal-cleaning methods. For example, exceedingly wet coal charged to the beehive oven was not deemed objectionable and at times was even considered desirable, but coal with a moisture content in excess of 8 per cent charged to a byproduct oven usually resulted in a loosening of the carbon deposit on the walls of the coking chamber, thus creating leakages which seriously affected the yield of byproducts. It was found that in some instances the centrifugal drier so successfully overcame this difficulty that it was no longer necessary to store the washed coal in draining bins before it was charged. It should by no means be assumed, however, that the centrifugal drier always can be used successfully, as many conditions may be encountered where it would not be at all suitable.

BONSON TABLE GAVE QUITE PROMISING RESULTS

Various methods of dry concentration developed but probably the first to attract serious attention was the Bonson dry concentrating table. Promising results were obtained in its first application to coal, but, unfortunately, those in control of this process failed to co-operate with men of the coal industry thoroughly familiar with the requirements and conditions to be met. As a result the improved table failed to accomplish results equal to those achieved with the original device, and interest in this process died out completely.

The next development of note was the introduction of the "Chance Process" by the T. M. Chance Co., of Philadelphia, Pa. In this process sand is introduced into the water in a suitable container and by agitation is maintained in suspension, thus creating a liquid of high specific gravity. Separation of the impurities from the coal is accomplished in a manner similar to that employed in the laboratory float-and-sink test, where zinc or calcium chloride is used to produce a liquid of the desired specific gravity.

It would be well to mention here that some ten or twelve years ago J. R. Campbell, chief chemist of the H. C. Frick Coke Co., patented and experimented on a commercial scale with a calcium-chloride process, but while the separations were exceedingly satisfactory other objectionable features developed which caused the abandonment of this effort.

When the T. M. Chance Co. started development of their process on a commercial scale in the Pennsylvania anthracite field gratifying results were obtained; but it was found that with the rectangular tank which they were using they could not obtain a constantly consistent separation of the impurities from the coal. Upon adopting the old and well-known inverted Robinson cone tank, however, this trouble was overcome.

H. R. Conklin has under development at one of the breakers of the Hudson Coal Co. at Scranton, Pa., a process quite similar to the Chance method except that in place of a coarse granular sand a fine material is

*First part of article on coal-washing practice [second part and appear in issue of Nov. 8.

used, preferably of high specific gravity and ground to pass a 200-mesh sieve. This process necessitates the employment of a Dorr thickener to reclaim the solids by which the desired gravity of the liquid is maintained. This process has shown some highly encouraging results. Its development and introduction is now controlled by the J. V. N. Dorr Co., of New York. No effort has as yet been made to apply either of these processes to the cleaning of bituminous coal on a commercial scale.

Coincident with these developments came the introduction of the Trent process. This is a radical departure from all other methods employed in the cleaning of coal. By agitation the pulverized coal is mixed with water and a suitable oil. The oil has an affinity for the carbon but not for the non-combustible particles. An amalgamation of the oil and carbon results. The ash reductions accomplished are quite remarkable as compared with results obtained by other systems of concentration. Some difference of opinion exists concerning the reliability of this process for the reduction of sulphur, also as to its practicability for cleaning coal to be used in the manufacture of metallurgical coke

Dry Tables to Be Operated at McComas

Almost simultaneously with the introduction of these various processes Sutton, Steele & Steele, of Dallas, Tex., introduced a dry concentration table. The general apathy existing with regard to any wet process resulted in almost immediate interest being taken in this new table. A plant was built and put into operation in Oklahoma, another in New Mexico and testing plants were constructed both at Dallas, Tex., and at Welch, W. Va. Finally, a contract was given for a completely equipped plant to be built at McComas, W. Va., for the American Coal Co. This should be ready for operation about Jan. 1, 1923.

The present inactivity in coal-washery construction probably arises from the uncertainty in the minds of coal men as to whether a more satisfactory dry process has at last been found. Many coal companies are ready to contract for coal-cleaning plants but are patiently waiting for conclusive proof of the efficacy of the dry process through its additional commercial application before deciding between wet and dry processes for their own operations.

Within the past year two additional dry processes have appeared, one known as the Seagrave dry concentration table, now controlled by Walter J. Sykes, of Danville, Ill., and the other known as the Stebbins dry concentration table, being introduced to the coal field by Briscoe & Stahl, of Detroit, Mich.

While much is claimed for the Seagrave table, based on results said to have been obtained in ore concentration, no machine yet has been built and tested on coal, and therefore its value to this industry is unknown. The Stebbins table also is a Western development. It is reported that this table is being quite extensively and successfully used in ore and borax concentration. Testing and development has been under way at Detroit on both bituminous and anthracite coal with gratifying results. This table doubtless will be heard from in the future.

At present, therefore, the situation seems to be one of uncertainty, first because of dissatisfaction with old wet concentration methods and second on account of the incomplete development of both the new wet and the dry processes. Much of the dissatisfaction with any wet process arises not so much from any inability to accomplish satisfactory reductions in ash and sulphur content as from difficulty encountered in dewatering the washed coal, also from attendant coal losses and undesirable operating conditions resulting from wet coal of the smaller sizes.

The use of the thickener greatly diminishes coal losses in the smaller sizes, yet a question may be raised as to its suitability to coal-washing work as compared to that of the old drag-chain sludge-tank method on account of the moisture content of the reclaimed coal. As a water clarifier the thickener is far superior to the sludge tank, but the reclaimed coal product is in a fluid state while that of the sludge tank is a wet solid and in better condition for intermixing without further dewatering with the rest of the coal product of the plant.

By simplifying the equipment needed in wet concentration and by reducing the number of the operations needed, the objection to the use of water for that purpose will be removed, especially if the dewatering difficulties and coal losses can be eliminated. Granting this, wet concentration may yet hold a most important place in the cleaning of coal.

I have purposely neglected to mention another development introduced by myself about four years ago in which the screening of the coal plays an important part. Before taking up the details of this process I wish to emphasize the importance of the screen in the future of coal concentration. In many instances it will be found that sufficient ash-and-sulphur reduction may be accomplished if the coarse coal only is washed, thus necessitating the screening out of the smaller sizes before the washing process is begun.

With dry concentration close sizing of the coal has been found advantageous. Scant success has resulted from efforts made to dry-concentrate coal below 16 mesh, and the difficulties and expense encountered in eliminating obnoxious dust where attempt is made to clean such sizes make dry concentration of fines of doubtful value.

Jig for Lump, Air for Slack, Use Dust Raw?

While fair success is reported in dry concentration of the larger sizes it has yet to be proved that such sizes can be more cheaply cleaned in this manner than by a jig. In many respects the intermediate sizes would seem to be the legitimate field for the dry process. While it may ultimately appear that some coals can be more efficiently and cheaply cleaned by wet process and others by dry, it is more than probable that a combination of the two will suit the majority of cases. Thus the screen is sure to enter the coal-cleaning problems of the future.

Prior to the introduction of screening equipment of a type wherein the screen cloth is electrically vibrated at great rapidity without movement of the heavy frame of the machine, the cost of screening coal in large quantity and through comparatively small mesh made consideration of such a process prohibitive. The data presented herein, however, will show the possibilities of the use of this type of screening equipment.

Attention is particularly called to the fact that instead of washing all the coal, the fines were screened out ahead of the washery and only the oversize from the screens treated, the unwashed fine material being bypassed and mixed with the washed oversize coal

Instead of this resulting in a higher ash and sulphur

content in the finished product as compared to that obtained when all the coal was washed, it was found that with the ash and sulphur in the raw coal the same, a much higher yield resulted. It also was discovered that by the use of such a method a considerably lower ash and sulphur content of the finished product could be obtained even though the yield still remained above that resulting from washing all the coal.

I do not claim that such a method will apply to all cases, yet I feel that as the coal upon which tests were made was a mixture from more than one hundred mines in the states of West Virginia and Pennsylvania, the results obtained would indicate that such a method may apply to a greater or less extent to many if not most of bituminous coals. Each operator finding it necessary to wash coal owes it to himself to investigate thoroughly his own product in order to determine whether such a method of operation would be helpful to him.

I know of at least one instance where an operation supplying large tonnages of steam coal for power-plant use has found that its customers, while naturally desirous of obtaining low-ash coal, are more vitally interested in obtaining fuel of a constant-ash content, as this renders it easy to obtain consistently efficient power-plant operation. In this instance careful investigation has shown that by washing coal that is retained on a 1-in. screen and mixing with the washed product all coal that will pass this screen, a product results that is not only of almost constant ash content but is also much lower in ash than the average steam coal on the market. Furthermore, the washing of only the coarse sizes results in no difficulties from high moisture.

What if the Smaller Sizes Are the Dirtier?

The elimination from the washery of the smaller sizes of coal will strike many as inapplicable to their own washery problems for the reason that some of these smaller sizes have the highest sulphur content of any of the sizes present. That was true also of the coal used in these tests. It might seem quite reasonable to assume that, under such conditions, the smaller sizes must be washed, yet it is more than likely that but few washery operations have ever had carefully conducted tests made to determine to what extent the sulphur content of the final product is affected by any sulphur reduction that may result from the washing of these small sizes. The same also may apply to the ash.

I feel that it is reasonably safe to say that, on account of the lack of such investigations, few are in a position to know definitely the real effect of washing these small sizes. It also would seem reasonable to assume that little is known of the portion of the average bituminous coal which can be but little affected by washing and that, on account of such portion being washed, some of it may not only be found as a part of the coal lumps apart from coal found with the refuse but may account for a considerable portion of the free coal in the refuse. Another condition that was brought to light in our work was that there are in some instances certain sizes of the coal which are more or less non-coking.

During the time that I was in charge of the coal washery section of the U. S. Geological Survey, before the formation of the present Bureau of Mines, I frequently noted the fact that the majority of coal washeries in this country produced a rather low-ash refuse and that usually this was due to the presence in the refuse of considerable coal of the smaller sizes. This not only applied to coals of the Eastern states but also those of the Rocky Mountain district. Later experiences with coal from various parts of the country and from the Argentine Republic and Alaska have brought this situation more and more to my attention, with the result that the tests were made, the results of which will be set forth in a succeeding article. I have also recently made a study of this situation in the Alabama field. David Hancock, consulting engineer and chemist, of Birmingham, Ala., has made extensive studies the result of which quite conclusively prove this contention as regards much of the coal in that district. He has devised a special chart upon which are graphically shown in a surprisingly effective manner the results of float-and-sink tests made upon the raw coal, and the washed coal and refuse products of various coal washeries in that district. Others in that field also have proved by similar investigations that it would be advantageous to bypass the fine coal around the washery.

Sandstone Dykes Through Whitehaven Coal

AS USUALLY interpreted a dyke is an igneous intrusion passing across the geological strata. Thus defined a sandstone dyke is an absurdity. The material could not be of igneous origin but the crack in which the sand was found might have been formed by an earthquake and so be due directly to volcanic action. If, then, the term may be permitted, dykes of sandstone have been found in the coal beds of Whitehaven, Cumberland, England.

They were described at a meeting of the British Association for the Advancement of Science by Professor A. Gilligan. The Whitehaven sandstones, extensively exposed in the cliffs along the sea front, show no such signs of cracks and sand fillings. The sandstone probably rests somewhat unconformably on the Lower Productive Coal Measures, and it is believed that the earthquake action occurred shortly after the period of deposition of the Lower Coal Measures and not later. Only in one case is the crack a true fault, and then the displacement is only 2½ ft.

The average width of the dykes is from 2 to 4 in., but sometimes they increase to 10 in. or dwindle down to mere films. The dykes are sometimes split. Veins of calcite and barytes traverse the dykes longitudinally and transversely and lenticles of shale and coal also are of frequent occurrence in some portions of the dykes. Professor Gilligan said that he believed that the dykes were filled by deposition from the unconsolidated sands that ultimately formed the Whitehaven sandstone. In the discussion Professor Kendall mentioned one or two examples of earthquake dykes which he asserted had been filled by sand forced up from below.

For the Purpose of Determining Specifications for the construction of concrete stoppings in coal mines that may be developed on the public lands of the United States, the U. S. Bureau of Mines, in co-operation with the Bureau of Standards, is constructing in the experimental mine at Bruceton, Pa., a chamber in which it is proposed to conduct tests to determine the strength of reinforced concrete stoppings when subjected to a pressure up to 50 lb. per square inch, suddenly applied. The tests require the construction of a permanent stopping, which was completed at the close of the fiscal year, and a test stopping, which is under construction in accordance with a design prepared by the Bureau of Standards. The work is under the personal direction of J. W. Paul, chief coal mining engineer, assisted by H. C. Howarth.

Crested Butte Field Produces Four Kinds of Coal From a Territory Five Miles Wide

Anthracite and Three Grades of Bituminous Coal Are Mined in This Cold Timber-Line Region—Lava Flows Have Matured the Coal, Leaving Three Per Cent of Volatile Matter

By Charles M. Schloss
Denver, Colo.

NOWHERE, perhaps, in the world can a greater variety of coal be found in as small an area as in the Crested Butte field of central Colorado. Four kinds of coal, ranging from a bituminous of low rank to an anthracite of high rank, are all mined within a circular area five miles in diameter.

Crested Butte lies in the Elk Mountains on the western slope of the Colorado Rockies. The field is handicapped by its isolation and by the fact that all it produces and all it ships in must travel by a narrow-gage railroad and be transferred to or from standard-gage equipment. It prospers nevertheless, distributing its anthracite over the entire western half of the United States as well as north into British Columbia and south into Mexico. The transference point is Salida, on the Denver & Rio Grande Western R.R. Here the Rio Grande Southern narrow-gage road commences its 316-mile stretch to Crested Butte.

That region at its five plants mined in 1921 only 197,228 tons of coal, a little over 2 per cent of the total output of Colorado during that year, that output being 9,141,947 tons. The four coals mined are all high-grade coals. They are respectively non-coking bituminous, a bituminous making a strong coke, semi-anthracite and anthracite. They will analyze as in Table I.

TABLE I—ANALYSES OF CRESTED BUTTE COALS

Type	Moisture, Per Cent	Volatile Matter, Per Cent	Fixed Carbon, Per Cent	Ash, Per Cent	B.t.u.
Non-coking	5 52	34.64	56 39	3 45	13,250
Coking	2 46	34 43	59 60	1 51	14,011
Semi-anthracite	0 40	10 80	80 60	8 20	14,430
Anthracite	2 70	3 32	88 15	5 83	14,099

The non-coking coal is an excellent domestic fuel, the coking is the equal of any heavy-draft locomotive bituminous coal in the United States, and the anthracite fully equal to that of Pennsylvania. The latter has the advantage over the better known coal in that Eastern state in being much freer from dirt, rock and bone. It is, further, with one exception the only commercially developed anthracite west of Pennsylvania, the one exception being a small bed at Los Cerillos, N. M., near Albuquerque.

Because of its excellence, Crested Butte anthracite enjoys an unusually broad market, bounded by the Pacific Coast on the west, Mexico on the south, Kansas City and Omaha to the east, and Canada to the north. Some goes to Mexico, some to British Columbia; one car found its way as far north as Nome, Alaska. Denver consumes more than any other city, San Francisco is next, and Kansas City third. Kansas and Nebraska, however, are the large consumers.

The operators in the field have standardized on the following sizes: Nos. 1 and 2, 2½ in. to 5 in.; Nos. 3 and 5, 1¼ in. to 2½ in., and No. 6, ¾ to 1¼ in. Nos. 1 and 2 are adapted for large domestic furnaces and open grates; Nos. 3 and 5, for base-burners, kitchen ranges, small domestic furnaces, and open grates; No. 6, for domestic furnaces with small openings in the grates, kitchen ranges, laundry stoves and for banking furnace and range fires. On the refuse piles of Crested Butte a third of a million tons of anthracite dust have accumulated. It is only in recent years that a market for this "carbon dust" has been found. Smelters manufacturing zinc oxide for paints find it a prime fuel and reduction agent.

To the one who seeks the whys and wherefores of natural phenomena the Crested Butte field gives much material for investigation and study. Geologists basing their hypotheses on the presence of porphyry masses and eruptive mountains credit the variety of coal found here to a flow of eruptive rock emanating from the main range and covering much of the sedimentary strata. The intense heat of the incandescent liquid rock meta-

MORE DISTANT VIEW OF CRESTED BUTTE FIELD WITH MOUNTAINS IN THE REAR

A truly mountainous region, some of the mines being 10,000 ft. above sea level. Buildings must be placed where snowslides will do least damage.

metamorphosed the bituminous to anthracite wherever it came anywhere near the coal. No trace, however, of the lava flow remains; it has been entirely removed by erosion.

Due to various rock movements the coal beds are more or less irregular in thickness. Many local, but not serious, faults are present. The roof and floor are either sandstone or shale. The bituminous beds vary in thickness from 4 ft. to 16 ft., the anthracite from 2 ft. 6 in. to 4 ft. The coal beds are either horizontal or on a moderate pitch. Many props are used, but their cost is not high. They are cut on the hillsides around the mines.

The coal at Crested Butte was discovered in 1879. Lack of shipping facilities delayed exploitation until 1881, when, upon the advent of the railroad, the first bituminous mine was opened. This same property has been producing ever since—more than 40 years.

From an engineering or mining standpoint Crested Butte offers nothing extraordinary. Its methods and machinery are not unusual. Two of the mine openings are so much higher than the railroad that gravity planes are necessary to land the trips at the dumps. The remainder are at tipple level. One mine sank a shaft but later abandoned it and began taking coal from another bed through a slope; the other openings are either drifts or slightly pitching slopes; the steepest has an inclination of 7 deg. Two are gaseous and use electric lamps; open lamps are used in the others.

In 1921 two shortwall coal cutters cut all the machine coal—only 3,641 tons. Longwall advancing methods are successfully applied by one company, room-and-pillar by the remainder. The machines operate in room-and-pillar workings. In 1921 55,323 pounds of black powder were consumed, that being used more than any other explosive. However, 5,415 lb. of permissible and 4,650 lb. of dynamite also were used. Haulage motors are conspicuous by their entire absence. Mules and hoisting drums substitute for them. Coal washeries and cleaning plants, likewise, are not found. Some refuse is picked out at the faces and the remainder in the screening plants.

Old Ruby Anthracite Mine, Now Abandoned

Note the trees around the plant growing up to levels near the timber limit. Climate is so cold that Japanese, Greeks, Mexicans and negroes avoid it.

Cable Cut by Rock from Bottom Shot Fires Crevice Gas

Ignition of Gas in Atmosphere Filling Longwall Face Fatally Burns Eighteen Men, Doing Hardly Any Damage in Mine of Canadian Collieries, Ltd.—Shot Said to Be Flameless—New Electrical Regulations

EXCELLENT as were the safety provisions at the No. 4 Mine of the Canadian Collieries (Dunsmuir), Ltd., at Cumberland, Vancouver Island, Canada, gas nevertheless collected in it and exploded on Aug. 30, killing eighteen men. A report made by George Wilkinson, former chief inspector of mines for British Columbia, who was given a special investigation commission by William Sloan, Minister of Mines, details the circumstances and gives advice as to the manner in which a repetition of such a disaster may be avoided. Of those fatally injured on this occasion only two were British, one being a Russian, six being Japanese and nine Chinese.

Briefly, Mr. Wilkinson finds that the source of the trouble was a flash, or open sparking, caused by an arc in the electric trailing cable at the socket used to connect this cable with the main electric circuit. This electric cable furnished the necessary power for the operation of a coal-cutting machine. The latter, a Sullivan alternating-current chain cutter, was of a type approved by the U. S. Bureau of Mines for use in gaseous mines.

New Rules for Electrical Operations

"After giving the matter careful consideration," says Mr. Wilkinson, "I would recommend the adoption of the following rules as part of the Coal Mines Regulation Act and would further suggest that the use of electricity be fully investigated by the Department of Mines, so that, if possible, definite conclusions may be reached as to the conditions under which the use of this power underground in coal mines may be permitted." The rules recommended are:

(1) The terminals of main feed lines in no case shall be located within 50 ft. of any coal face. (2) The current shall be cut off and the cables made dead in that vicinity when blasting, and the current shall not be switched on again until blasting is finished and the places are examined and pronounced safe and until the cables have been examined and found free from any defect. (3) All permanent electrical installations and transforming stations underground shall be made fireproof. (4) All switches and terminal connections shall be protected or enclosed so as to prevent persons coming accidentally into contact with them, to avoid danger from arcs or short-circuits resulting from fire or water. Where there may be risk of igniting gas, coal dust or other inflammables, all parts shall be so protected as to prevent open sparking. (5) All cables used underground shall be covered with insulating material, and, where high voltages are used, properly armored cables of standard thickness shall be provided. (6) All trailing cables shall be of properly armored construction whatever voltage is used.

Confidence is expressed that these rules will give an additional margin of safety. Rules 1, 2 and 3, it is asserted, should be put in force at once. As for Rules 4, 5 and 6, it probably will require three months to obtain and install the armored cables and other material required to make them effective. Mr. Sloan already has taken the action necessary to give these recommendations the effect of law. Orders in council have been passed and from Oct. 2 the rules enumerated have been a part of the Coal Mines Regulation Act. In the course of "general remarks" the report reads:

"It was a small explosion to take such a heavy toll and only a combination of circumstances made it do so. Occurring on a longwall face many men were in the path of the flame despite the short distance it traveled. As most of these men were working at the face and the seam was not thick, they could not escape. It is my opinion that if the current had been cut off the cable while the shot was being fired there would have been no explosion, and the fireboss erred in not requiring this to be done seeing that the terminals of the feed cables were in such close proximity to the shot.

"The terminals of the main feed line should not have been located so close to the face and fixed flameproof terminals should have been used. I do not mean to infer that an arc could not have been created if the terminal boxes had been installed, for if the blow had been of sufficient force to draw the bare end of the connecting cable clear of the insulated material, an arc might nevertheless have been created, but the chances of this happening would have been decreased. It is questionable whether, owing to the quantity of gas liberated by the strata and the peculiar conditions existing, it would be wise to continue the use of electric mining machines in this section.

"Up to the present, because electric power has been used to only a limited extent in the mines of British Columbia, no specific regulations governing its use have been made. No doubt it will be used more extensively in the future as it already is in the coal mines of the United States and Great Britain.

Danger Lurks in the Cable Connection

"These electric coal-cutting machines were installed by the Canadian Collieries (Dunsmuir), Ltd., nearly seven years ago, and the recent accident is the first recorded. Though the machines are approved by the U. S. Bureau of Mines, their safety must be judged by the weakest link, which in my opinion is the cable and especially that connection which is in close proximity to the working face.

"Edison electric safety lamps are used throughout the mine. The only exceptions were the few flame safety lamps used for testing purposes. No one was permitted to blast the coal in this section, and most of the bottom lifting was done without blasting. Explosives were used only in places where the rock was so hard that it could not be lifted without it. Even then only permissible explosives were used.

"It is hard for the higher officials and the inspectors to watch every detail in a mine of this size. The terminals of the main lines are being moved from time to time, and this detail comes mainly under the control of the under officials. Enough electricians were employed to do this work, and an adequate number of certificated officials were employed to supervise it. In

addition to the large staff of regular officials, the company employed a safety engineer who holds a first-class certificate of competency. He constantly patrols the works inside and out, checking up and pointing out any defect that may cause accidents."

The mine has but one main entrance from which at a point 75 ft. from the portal two slopes diverge, No. 1 slope being 7,000 ft. long and running due north, and No. 2 slope being 9,000 ft. long and running north 45 deg. east. Levels have been turned off the latter slope in an easterly and westerly direction.

The explosion occurred in what is known as the longwall district off No. 20, East Level, No. 2 slope. Part of the face is machine-mined, the coal from that part being shoveled into cars by loaders. Another part is worked by hand miners. A trailing cable 200 ft. long connects the main circuit to the machine.

With reference to the condition of the mine as to gas, Mr. Wilkinson quotes the daily reports of firebosses from Aug. 28 to Aug. 29, the inspectors' reports for the months of June, July and August, and the gas committees' reports for the same three months. From these reports, he observes, it is plain that much gas is being made in this section of the mine, chiefly due to the roof breaking through to a small seam of coal about a foot thick which lies about 15 ft. above.

The firebosses' reports show that explosive gas has been found in small quantities in No. 3 level and other places in that vicinity and that a ½-in. gas cap was obtained at points along the roof line, but that it was less as the lamp was lowered and probably did not exceed ½ in. from No. 3 level to the end of the longwall face. No explosive gas or gas caps have been reported below No. 3 level.

According to the length of the flame caps and their relation to percentage, as shown in a pamphlet issued by the Department of Mines, the above-mentioned caps of gas are equivalent to 2.08 per cent and 1.08 per cent respectively. The low explosive limit is 5.5 per cent. The withdrawal point as set by the Coal Mines Regulation Act is 2.5 per cent, leaving a margin of safety of 3 per cent. But the margin in this case appears to have been 3.42 per cent.

Many Deaths but Little Explosive Violence

Mr. Wilkinson states that conditions as he found them in his examination of Sept. 1 indicated that the mine had been little damaged by the explosion. He goes on to tell in detail of the conditions in each level visited. Regarding No. 1 slant off No. 4 level* he says: "About a ½-in. gas cap was obtained in this place and an atmosphere that was explosive in a cavity on the right side of the roadway above the terminals of the main circuit of the electric power line. The trailer cable from the mining machine is connected with the main line at this point.

"A shot had been fired in the floor of this place, and it was almost simultaneously with the firing of this shot that the explosion occurred. A rock flying from the shot had come in contact with the trailing cable with sufficient force to break the insulation and bare one wire and had also torn one of the three connecting wires from the socket where they were connected with the main circuit. The shot had done its work well.

"No damage was done in this place but much dust was deposited on the timbers. The shotlighter with two of the workmen out of the place stood in No. 2 roadway off this slant about 30 ft. distant from the shot. They were slightly burned on the face, hands and arms. A car standing about 45 ft. from the face had not been moved. In No. 3 slant, No. 2 level, No. 1 place, there was no damage. A car was standing at the face and apparently had not been moved. The badly burned body of John Johnston, a miner, was found on the slant about 80 ft. back from the face.

"In No. 2 place, off No. 3 slant, No. 2 level, there were signs of considerable heat from flame. Two shovels were standing against a cog on the face line in this place. There had not been sufficient force to move them. In No. 3 slant a 5-ft. post was found with the saw in position for cutting. A car was standing undisturbed."

Ignition of Gas Rather Than an Explosion

Commenting on the evidence Mr. Wilkinson asserts that the outbreak may better be termed a burning of gas than an explosion. He adds: "It would appear as if the percentage of methane had bordered on the lower explosive limit. The flame passed up the longwall face with the air current. The shotlighter, who was standing 30 ft. below the point where he was firing the shot, was only slightly burned. E. McAdam, who was working in No. 1 level, about 700 ft. up the face, did not see any flame, consequently the distance it traveled along the longwall face did not exceed 750 ft."

It is stated that conditions point to No. 1 slant of No. 4 level as being the point of ignition. It was in this place that a shot was fired in the bottom, as described. The roof in the place is broken and full of slips and crevices, and there is a cavity which has a length of 8 ft., a width of about 1½ ft. and a height above the roof line of about 1.2 ft. Fissures and crevices extend back into the gob; to what distance and height is unknown. A fault with an approximate downthrow displacement of 3 ft. had been crossed by the place above this. It had run out before it reached this place, but it extended for some distance in the opposite direction. This resulted in a considerable area of exposed roof being badly broken, and no doubt the breaks in this roof continued upward to the small seam which overlies the one being worked. The crevices made by these breaks would provide a large storage space for methane, as the ventilating current could not be diverted to clear them. This gas also would be out of reach of anyone testing, as a safety lamp could not be got into the crevices.

Small quantities of explosive gas had been found in several places on the return side of No. 1 slant for some time prior to the explosion. This being so it is not safe to presume that the crevices higher up, which could not be examined because of their inaccessibility, also contained methane. The distance traveled by the flame was not great, and it died out after passing the working places in the disturbed area, showing that there was lack of explosive material elsewhere.

Commenting further on the cause of ignition it is stated that the main three-phase circuit was carried up No. 1 slant, No. 4 level, to a point approximately 16 ft. from the coal face and about 4 ft. from the end of the bottom lifting. The top cable was about 1.7 ft. below the roof line and the bottom of the cavity. The lower cable was about 3 ft. above the top of the rock to be lifted. Mr. Wilkinson speaks again of the break-

* Apparently all these areas relate to longwall district No. 20, East Level, No. 2 slope. This No. 1 slant is not the first level in the mine but the first in the district. Furthermore, the longwall face apparently extends from No. 1 level to No. 4.—Editor.

Moodlal, a permitted explosive, was used.

ing of the wire by flying rock following the firing of a shot and asserts that there must have been considerable flash from the arc so created. The break occurred only about 2 ft. from the cavity.

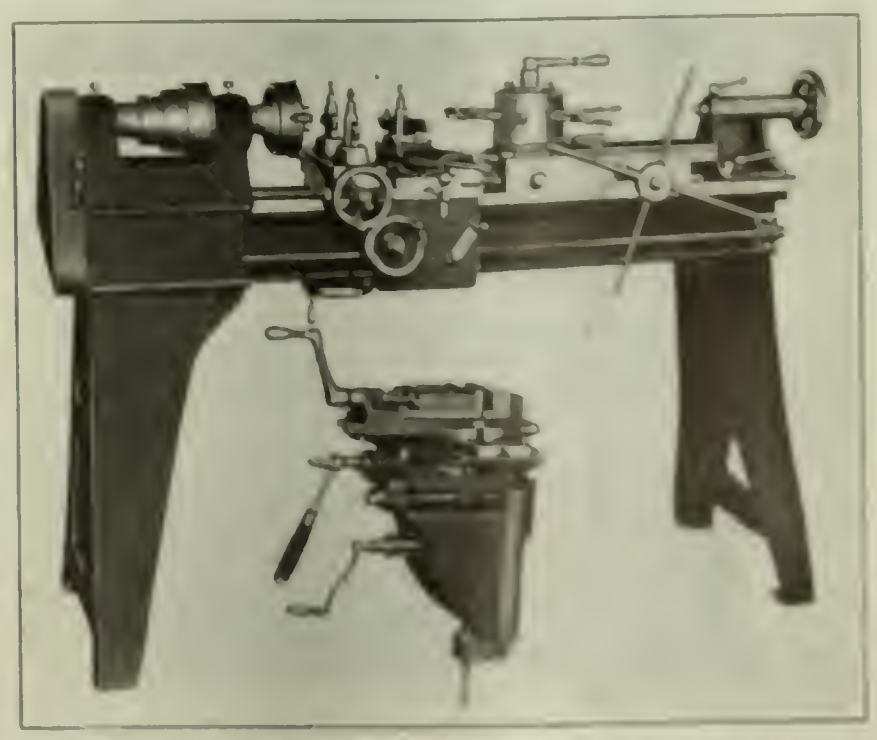
There were only two possible sources of ignition; one, the arcing of the electric circuit, and the other, flame from the explosive in the shot. The shot was a good one, according to Mr. Wilkinson, and the chances that any flame resulted are remote. It was some 8 ft. from the cavity, whereas the junction point of the trailing cable was only about 2 ft. distant. He adds: "From conditions as seen after the explosion I have to conclude that actual ignition must have been from flame or sparking from the electric wires."

References are made in the report to the evidence of the fireboss at the inquest to the effect that he had carefully examined the place before firing the shot and found no gas and also that he had examined the cavity in the roof with similar results. Mr. Wilkinson expresses doubts of this. It is possible, he says, that this was done, and that there was a change between the time of examination and the firing of the shot. However, assuming that the cavity was clear, so far as could be ascertained by the fireboss, the crevices above it no doubt contained gas.

On June 26, 22,000 cu.ft. of air were provided for the use of sixty-two men and eight mules; on July 25, 20,000 cu.ft. were supplied, and on Aug. 11, 25,000 cu.ft. were circulated for the same number of men and mules. The amount passing is nearly three times that required by the Coal Mines Regulation Act under normal conditions, according to Inspector Jackson's reports. Since the installation of a booster fan, electrically driven, for augmenting the ventilation the quantity passing in this district has been increased some 6,000 cu.ft. per minute.

Officials of the Canadian Collieries are said to have been faced with unusual difficulties in the ventilation of the mine, which is of large extent, having been operated for thirty years or more. Large extraction of pillar areas in the earlier days of operation, without any thought for the future, has made many difficult problems which the present-day management is endeavoring to solve. Thomas Graham, the superintendent, and his staff have made many improvements in the past five years. Among these are "the building of permanent stoppings with a gunite finish on main airways practically throughout the mine, the installation of a second fan of the Sirocco double-inlet reversible type with a rated capacity of 200,000 cu.ft. per minute against a 6-in. water gage and the construction of a new and separate return airway through the old works for practically the whole length of the slope."

Work Both Wood and Metal on One Machine



ONE of the "side issues" of every coal mine—one of those things that contribute nothing directly to the extraction of coal yet without which little coal would be produced—is the mine shop. In the old days this was a blacksmith shop pure and simple—a place where mules were shod, picks sharpened and drills and augers dressed. With the passage of years, however, the equipment of the mine has changed and similarly the needs of the shop. The electric locomotive, the coal cutter and various mechanical appliances of a similar nature necessitate a type of repair impossible with only forge, anvil and possibly hand drill press.

Of all the machine tools yet invented it is well recognized that the lathe, being the most flexible, possesses the greatest possibilities. American manufacturers have developed this machine to a high state of perfection; that is, they have developed many special lathes adapted to special uses. In the mine shop, however, particularly if this shop be small, the special tool is the type to be sedulously avoided. On the contrary, the kind of lathe most to be desired is an "all around" machine or what might be termed a jobbing lathe—that is, one upon which a great variety of operations may be performed without its being specially designed or adapted for any one in particular.

In the accompanying illustration is shown a lathe recently placed on the market and well adapted to the small shop having a variety of work to perform. This lathe is designed for turning either wood or metal and is made rigid enough to withstand the possible high-speed vibration of the former and the heavy cuts of the latter.

Possibly of most interest to mining men, however, is the large number of attachments with which this machine may be provided. For metal working these include grinders, buffers, millers, gear cutters, etc., and for woodworking they embrace sanders, grinders, buffers, polishers, band saws, jig saws, jointers, planers, saw tables, mortisers and the like. Of course, the procurable equipment includes raising blocks, a compound rest and a turret. Many others also are available, built especially to fit this machine.

Thus it will be seen that this machine is adapted to the performance of many operations. The attachments, such, for instance, as the band saw, take up far less floor space than would separate machines performing the same service. When not in use these may be taken off and set to one side out of the way. This machine is being built and marketed by the Little Giant Co., of Mankato, Minn.

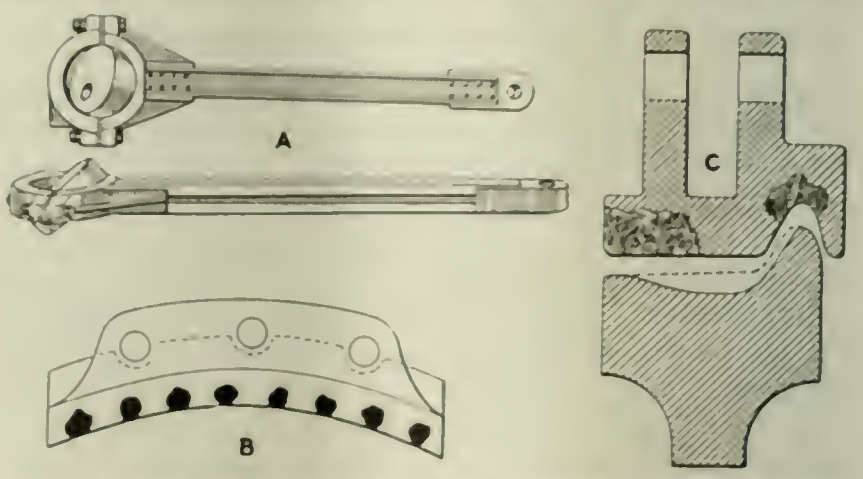
Huntington Show Suggests Modern Ways of Reducing Coal Cost—II



Abrasives for Keeping Tires in Condition—Self-Renewing Water-Softening Material—Means of Ridding Mine Towns of Typhoid—Buckrt Conveyors—Helical Gears

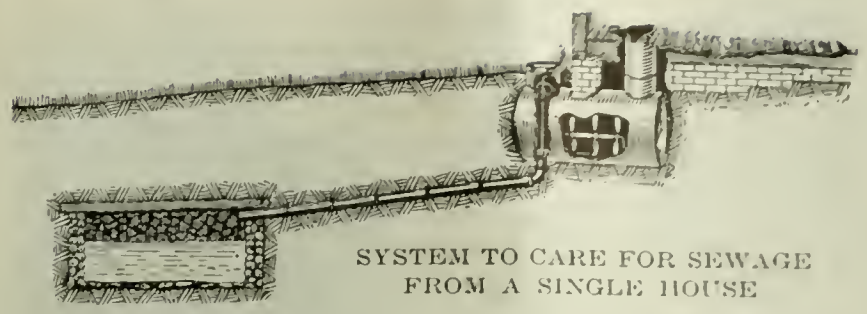
IN AN ARTICLE regarding the Huntington Coal and Industrial Exposition, Sept. 18-23, appearing in *Coal Age* last week, the wide, low, capacious mine cars of the West Virginia mining region as shown at several booths were described as well as an electric rivet heater and a mine hoist of large rope capacity.

At another booth was an exhibit of "feralun," the substance which, set in a brake wheel, wears off false flanges and so makes it unnecessary to take the wheels off their axles, to turn down the tires and replace the wheels, to lay off mine locomotives temporarily while this work is being done, and to renew shoes. Moreover, wear and tear on frogs and switches are prevented by this grinding, as also the derailments that are the result of false flanging. The cutting of fishplate bonds is avoided and electric welded bonds if attached to the upper part of the rail are protected from injury.

When the brake shoe with abrasive material imbedded in it has ground down the false flange, the body of the shoe that has no cutting abrasive rests on the main portion of the wheel, the part that runs on the rail and is worn by traction and sparking, and the cutting substantially ceases except as much as is necessary to keep

UNIVERSAL-MOTION ECCENTRIC AND ABRASIVE SHOE

A is an eccentric for use with shakers or in other places. With it proper alignment is a matter of no consequence, as the eye is a self-oiling ball. *B* shows locomotive shoe with abrasive material set in the tread and *C* a cross-section of such a shoe and part of the wheel on which it acts. When the wheel has worn down as shown the abrasive wears off the "false flange" and restores the surface.



the wheels true. Abrasive shoes are put also on new wheels to prevent them from getting out of shape. The keeping of false flanges off tires saves the rail surfaces from much wear.

Interesting also was the exhibit of the Permutit Co. Permutit is a zeolite (so called because it intumesces or acts so rapidly as to be said to boil when acting on the hardness in water). It is a sodium aluminum silicate that exchanges its sodium for lime or magnesia when those elements come in contact with it in the form of the hardness in water. It has the advantage that it can be regenerated by passing through it common brine (sodium-chloride solution). In consequence when permutit is used to soften water before its introduction into the boiler of feedwater heater, the chemical after change need not be thrown away but can be used again and again after it has been regenerated by brine. The regeneration cycle is ordinarily arranged to take place at night, when the plants are closed, or two softeners are placed in parallel to give a 24-hour continuous serv-

SOFTENING PLANT AT HUNTINGTON, W. VA.

This unit was installed at the mine of the Huntington Coal Co., in Mingo County, W. Va. The plant delivers 84,000 gallons of hot soft water daily from a river containing an average of 44 grains of hardness per gallon. By use of two alternating units the water is softened continuously 24 hours per day.

SYSTEM TO CARE FOR SEWAGE FROM A SINGLE HOUSE

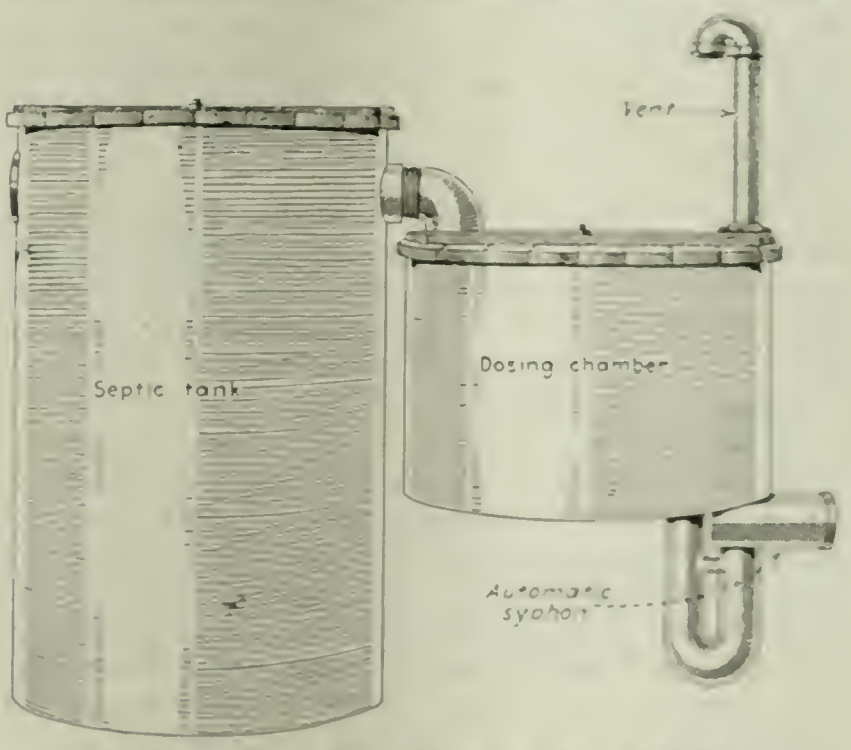
In this illustration the porcelain parts of the toilet are omitted. The fecal matter falls into a circular tank which contains a digesting solution. The material to be rendered innocuous and fluid is both moved forward and agitated by paddles, which themselves are set in motion by the opening and closing of the lid of the toilet. The overflow, a harmless effluent, passes to a cesspool and is absorbed by the subsoil.

ice, one softening the water while the other is being regenerated for further usefulness.

Overdosing the water does not produce any harmful effluent, no matter how soft the water may be. In consequence there is no need for watchfulness in this regard. In fact the rule is to overdose the water so that water of zero hardness may be produced. With hydrate of lime or soda ash a certain degree of hardness still remains in the water, because the bodies resulting from the reactions are themselves soluble in water and because colloids form which refuse to settle.

Another advantage is that permutit forms no sludge. In consequence the effluent does not need to be held for sedimentation and no sludge has to be discharged. Yet another quality of value is the rapidity with which the zeolite works. Permutit is said to do in 10 minutes what would take an ordinary reagent four hours to perform when cold. Thus the volume of water under treatment at any one time can be greatly reduced with reduction in the size of the treatment tanks. Pumps may not be needed, as the permutit treatment tanks are connected under pressure with the line and do their feeding under the line head.

All of which seems like a record of perfection. There is a drawback, however. Though the zeolite is never discharged it has to be regenerated with salt, which though cheap is not obtainable without expense. The lime treatment is only half as costly as the zeolite for temporary hardness. On the other hand, the soda-ash treatment is twice as expensive as the zeolite where the hardness is permanent. Viewed in that way where the hardness is half temporary and half permanent the zeolite treatment is just about as expensive as the combined lime and soda-ash treatment, chemically considered. However, the reduction in tank size and the absence of sludge is in favor of the permutit, and a further benefit is found in the fact that the water is softened to a zero hardness and does not contain any excess reagent or any soluble products from the reaction. Still, permutit, though the preferable as a softener of permanent hardness, cannot compete in cost with lime as a means of removing temporary hardness. Therefore the best practice is often to use lime for the latter and permutit for the former. Whether to do so is a matter for expert determination.



SIMPLER MEANS OF PURIFYING SEWAGE

The fecal matter falls into a tank above the floor level, is digested by the fluid contained therein and overflows through a pipe to a barrel drilled with holes. The purified fluid passes into the subsoil.

The Kaustine Co., Inc., exhibited its line of sanitary products and here it may be said that one cannot be favorably impressed with the sanitary conditions in mining villages with the houses perched often above one another and sewage seeping down from the imperfect vaults now in general constructed. The evil is perhaps not painfully apparent. It takes a medical man to realize it. There has been little objection made by the residents of mining villages, though they are the persons subjected to the evil effects just described. Still, many mine operators have sensed the dangers of seepage and flies and wondered whether they could not make their village more typhoid-proof.

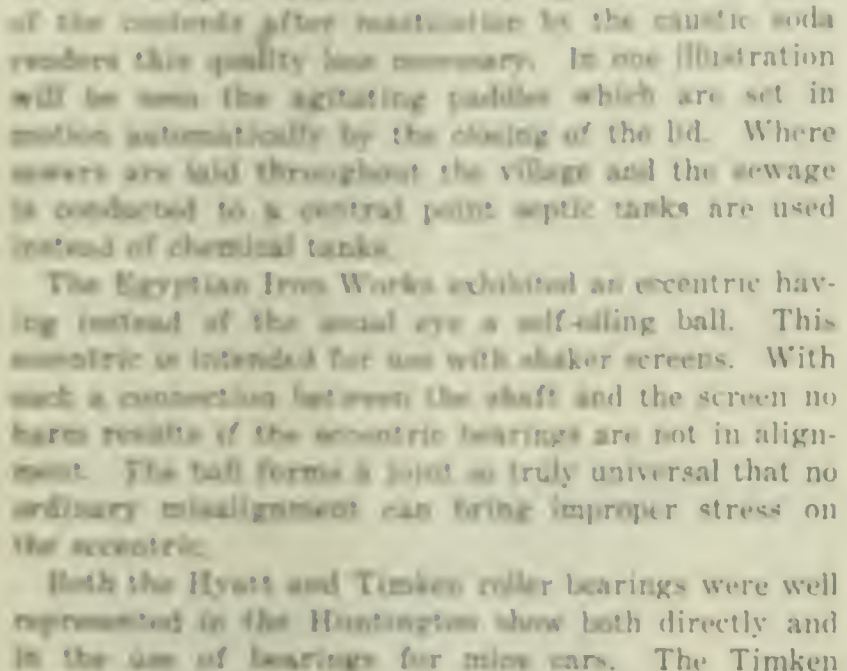
I am told that the owners of many mining plants in West Virginia are not only aware of the danger but are ridding themselves of it. In the issue of *Coal Age* of Sept. 14 was a description of a convenience in the mines of the Ford Collieries Co. whereby the fecal matter was rendered not only innocuous but truly fluid by the use of a chemical. This outfit was furnished by the Kaustine Co. J. L. Murphy informs me that commercial caustic soda is not the only ingredient in the preparation used as a disinfectant, deodorant and digestant of this fecal matter but that, in order to make the action more rapid, many other ingredients are used and the strength greatly exceeds that—3 per cent—mentioned by Dr. R. R. Sayers as competent to perform the work demanded. Mr. Murphy says that as rapidity in operation is desirable, dosages are applied greater than those which if given plenty of time will do the work effectually.

WHERE MUCH SEWAGE IS TO BE TREATED

A septic tank is used first. In this no chemical is used. The microbes which work in the unaërated fluid below the scum that forms in this tank rapidly purify the sewage. The much-modified sewage overflows from this tank into the dosing chamber, where the assurance of complete purification is made doubly sure. It is discharged from this chamber discontinuously by an automatic syphon.

The illustrations herewith do not include the plumbing with its ventilation pipe and in some cases as shown there is no plumbing; only iron parts are provided, with an iron lid, as shown in one illustration. It has been found that porcelain parts fare but ill in some of the residences and even in the bathhouses around the mines.

All the illustrations shown are for single units, but multiple units are provided where these are desirable for schools, stores, bathhouses, churches, assembly rooms, clubhouses and like places.



Caustic soda has a disastrous effect on galvanized vessels, as these are made of Armco iron, which is 99.84 per cent pure. This is covered with an enamel that is unaffected, it is said, by acids, alkalies or the elements. The top of the tank is fitted with a revolving trap which serves to keep the tank reasonably tight, but the nature of the contents after sterilization by the caustic soda renders this quality less necessary. In one illustration will be seen the agitating paddles which are set in motion automatically by the closing of the lid. Where sewers are laid throughout the village and the sewage is conducted to a central point septic tanks are used instead of chemical tanks.

The Egyptian Iron Works exhibited an eccentric having instead of the usual eye a self-oiling ball. This eccentric is intended for use with shaker screens. With such a connection between the shaft and the screen no harm results if the eccentric bearings are not in alignment. The ball forms a joint so truly universal that no ordinary misalignment can bring improper stress on the eccentric.

Both the Hyatt and Timken roller bearings were well represented in the Huntington show both directly and in the use of bearings for mine cars. The Timken Roller Bearing Co. lays stress on the ability to take up wear in the bearings while eliminating that in the running gear.

The Jeffrey Machine Co. showed a full-sized loading machine which loaded coal all the day long. The Westinghouse Electric & Manufacturing Co. had a bar-steel conductor-cable-reel locomotive running on trucks and both the Westinghouse and the General Electric Co. had an exhibition of their automatic substation equipment.

A. Leschen & Sons Rope Co. had a model illustrating its equipment at the mines of the Bradshaw Coal Co. at Bradshaw, W. Va., on the Dry Fork Branch of the Norfolk & Western R.R. The coal is 600 ft. above the railroad and the point nearest the railroad is 1,200 ft. distant therefrom. This company had been using a surface incline to reach the bottom of the hill and mules to haul the cars over the Dry Fork of the Tug River. The rope is supported only at the ends and it has a rated capacity of 125 tons per hour, or 1,000 tons per day of eight hours. However, one man can readily lower 50 per cent more and do it safely. The span is 1,320 ft. and the fall 580 ft., the cost for operation being approximately 1c. per ton.

TIPPLE AT THE STATION, BRADSHAW, W. VA.

The plan of bringing on a further level a grade 600 ft. above the railroad and approximately 1,200 ft. distant therefrom, through which the cars of coal from the mines were transported by means of the bucket over the hill.

ANOTHER VIEW OF ROPEWAY

Only two buckets are used, one going up while the other goes down. Rope incline handles 1,000 tons in 8-hour day.

The R. D. Nuttall Co. had a booth where were displayed the helical gear reduction units by which continuity of contact, reduction of noise and vibration are attained. With such a gear the load is transferred from the pinion teeth to the gear teeth progressively, gradually and without shock regardless of how badly they are worn. They do not drive by a series of impacts, as is inherently the case when an ordinary pinion drives a spur gear. It is asserted that the wear being uniform permits a new pinion to be applied to a worn gear with satisfactory results. Compared with ordinary spur gearing the teeth have a greater rolling contact and are provided with a large quantity of metal at their roots. Unlike a herringbone gear the pinion can float across the main gear without injury. These gears are suited for many purposes, among them for driving hoists and pumps. At the Carnegie Coal Co.'s plant at Atlasburg, Pa., a helical gear of this kind has been installed for driving a 12-ft. exhaust mine fan, replacing the steam drive.

The Nuttall firm also showed a trolley and pole head for holding it. This trolley is provided with a centering spring that brings the wheel back to its normal position. Instead of the pole head covering the sides of the pole it covers the top and bottom. In consequence when the trolley escapes from the trolley wire and hits against an offset in the roof or on the edges of cross beams, the blow falls on the steel fork and not against the wood of the pole. This prevents it from being shattered. The cable is firmly clamped to a grooved plate, using bolts instead of set screws. The motorman is almost sure to have a wrench with which he can tighten up the connection should that be necessary, yet is quite likely not to be provided with the wherewithal to tighten setscrews where these are used to clamp the connections to the trolley-pole head.

AT THE PITTSBURGH (PA.) experiment station of the U. S. Bureau of Mines, J. D. Davis, fuels chemist, and J. F. Byrne, research fellow, Carnegie Institute of Technology, have investigated the relative tendency of Pennsylvania coals to ignite spontaneously. The research consisted largely in the development of methods for the determination of the comparative sensitivity of coals to oxygen.

Problems of Operating Men

Edited by James T. Beard

Where Coal-Mining Practice Could Be Materially Improved

Examination Started Too Long Before Men Enter the Mine for Work—Practice in the North of England —Economy in Handling Coal at the Working Face

BORN in England and starting work at the early age of 13 years, for ten years I labored there as a miner's helper and doing various kinds of work about the mine, before deciding to come to this country.

Looking back over that early experience in England and judging it by what I have seen in American mines, I find there is much to be learned by way of comparison. In the fifteen years that have passed since I came to America, I have worked in many coal mines from southern Illinois to British Columbia. During that time, my eyes have not been closed to what has been going on about me and I find that many lessons can be learned through close observation and comparison of the means and methods employed in different localities.

Firebosses Start Examination Too Long Before Men Enter Mine

It was reading the numerous letters that have appeared in *Coal Age*, regarding the fireboss' identification mark, that leads me to offer a few comments on this work. I am deeply impressed with one fact; namely, in the large majority of cases, the fireboss starts his examination too long before the time for the men to enter the mine for work.

In Illinois, it was a common thing for a fireboss to start his examination eight hours before the beginning of the morning shift. I found that this was wholly in compliance with the coal mining laws of the state, where the mine examiner is required (Sec. 21) to examine the underground workings of the mine within eight hours preceding the time the dayshift goes on duty.

Let us assume, for example, that a fireboss begins, say at 1 a.m., to examine a section of a mine in his charge. In his examination, we will suppose that he finds a small quantity of gas in several of the places, but not sufficient to render work in those places dangerous.

Now, we will assume that a big cave takes place on the intake or return airway of that split, after the fireboss has completed his examination. As a result, the circulation is choked and gas accumulates in the section. Believing everything to be safe, the men are admitted to the mine and proceed to their several places. It is nothing strange that conditions such as these bring calamity.

At other times and places where the fireboss starts his examination only two hours previous to the entrance of the miners for work, I have known of places that were found to be clear of gas at the time the examination was made; but a cave occurring a little later would knock down a brattice and short-circuit the air, allowing gas to accumulate at the face in a very short time.

Booster Fans Installed in Mines, Menace to Safety

Again, I have observed gaseous places that were hard to ventilate and required a small blower or booster fan to keep them clear of gas. Let me ask, Who knows when the belt driving such a booster is going to slip or break; or when a cave will tear down the wire that conducts the power to operate the fan? Either is liable to occur at any time and the fan be put out of commission.

In some localities, bumps are frequent, causing roof falls that destroy brattices and short-circuit the air. This may take place at a time between the examination by the fireboss and the entering of the men for work.

Practice in North of England

Allow me just here, to refer to practice in the North of England, where the firebosses enter the mine only an hour previous to the beginning of the miners' shift. The mine manager is at the shaft bottom to receive the firebosses and give them any orders that might chance to be left by the night-shift overman.

The examination by the firebosses being completed, if everything is reported safe for work, the men are checked in, each miner being given a safety lamp before he leaves the shaft bottom. Every lamp has been examined and locked and often the men are searched for matches before being permitted to enter the mine.

It goes pretty hard with a man who is caught with matches on his person. The officials are sure to make an example of him, by imposing a fine or hailing him to court for imprisonment. At the entrance of each section, the fireboss in charge awaits his men and there is no chance for a man to enter his place when it has been found to be in an unsafe condition for work.

When a fireboss has admitted his men to their respective places, he devotes the balance of the shift to a careful examination of the shots and timbering, in each working place. All shots must be properly mined and tamped before they can be fired.

Improvements in Loading Coal Adopted in Montana Mine

I was pleased to note a reference made in *Coal Age*, Aug. 24, p. 288, to the improved method of loading coal at the working face, as adopted by the Keene mine management, at Roundup, Mont. It appears that the company have been studying more economical methods of mining and handling the coal at the working faces, in the rooms.

The plan adopted of standing from three to five cars at the face of a room, the cars to be loaded at one time, will expedite the work and reduce the cost of gathering cars in the workings. The new plan, no doubt, calls for an investment of several hundred dollars for extra mine cars; but this expense will be more than offset by the reduced cost of operation.

Coal-Face Conveyor System

In the mining of a seam of low coal overlaid with a good roof, allow me to suggest that there is much economy in the use of a conveyor system laid parallel to the coal face. Such a conveyor, operated by a small electric motor, will afford easy loading all along the face and will be found a profitable investment.

Not the least of the advantages of a conveyor system at the working face is the fact that little or no brushing of the roof is necessary. As the conveyor works along the floor, miners can load commercial coal with the greatest ease. A chunk of coal that requires two men to roll it onto the conveyor will generally be carried along without further trouble.

A conveyor system of this kind is generally protected by a series of cribs. As the face is advanced and the conveyor line shifted forward, new cribs are built and the old ones removed, allowing the standing area to cave. Whether a conveyor is installed or a track is laid along the face of the coal, there is provided an ideal longwall system that will prove a source of great

seeming in the operation of the mine and reduce the cost of production, which is a most important item in present-day mining.

In a pamphlet just received from England, I read that a large coal company offered a prize for the best solution of the question: "What is the most important job on the colliery?" While we are told that the judges decided that the general manager held the most important position at a coal mine, our own opinion is that the position of the fireboss is more important than that of any other mine official. It would be interesting if *Coal Age* readers would discuss this question, giving their ideas of the relative importance of mine officials.

Kemmerer, Wyo. WILLIAM ALLAN.

Steel Guides and Buntons in Mine Shafts

Steel cage guides and shaft buntons in use in Europe fifty years ago—Description of modern Belgian coal shaft in Campine region.

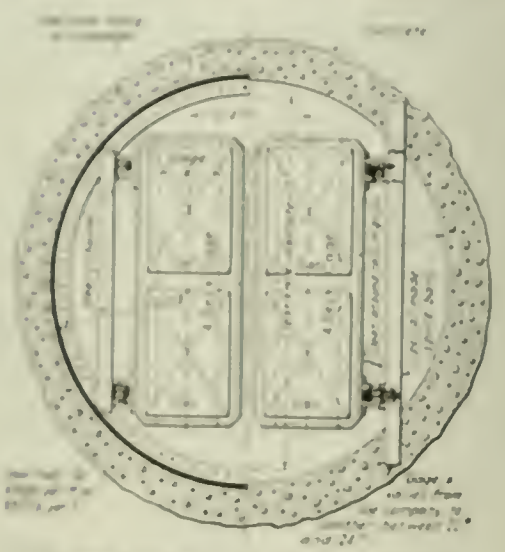
IN DESCRIBING the equipment of the Rosedale Shafts, in *Coal Age*, Sept. 7, p. 414, George A. Richardson appears to be under the impression that the use of steel rails as cage guides, in mine shafts, is something novel. He calls it a "revolutionary development."

As a matter of fact, steel rails have been used as guides in the deeper coal shafts of the European continent, ever since such rails have been rolled commercially, and that is, since the early stages of the Bessemer-process development, which would put us back fifty years, or say to the seventies.

But, even before that time, when railroads were using iron rails they were using rails as cage guides in Belgium. In the sixties, Alphonse Briart, a famous Belgian mining man of those days, replaced with iron rails the wooden guides in all the hoisting shafts of the Marchienne-Basseup Collieries. There were eight or nine of these shafts, some of which were deeper than 1,000 ft.

USE OF IRON RAILS AS SHAFT GUIDES FIFTY YEARS AGO

From the beginning, Mr. Briart made use of the heaviest rails procurable. At that time, two kinds of rails were being manufactured, currently, on the continent: the flanged rail with which we are familiar in this country and the two-headed type, which still survives in the British Isles. Mr. Briart used the former as cage guides, while the latter, placed on edge, served as buntons. More than half a century ago, therefore, rails were not only used as guides, but for buntons as well.



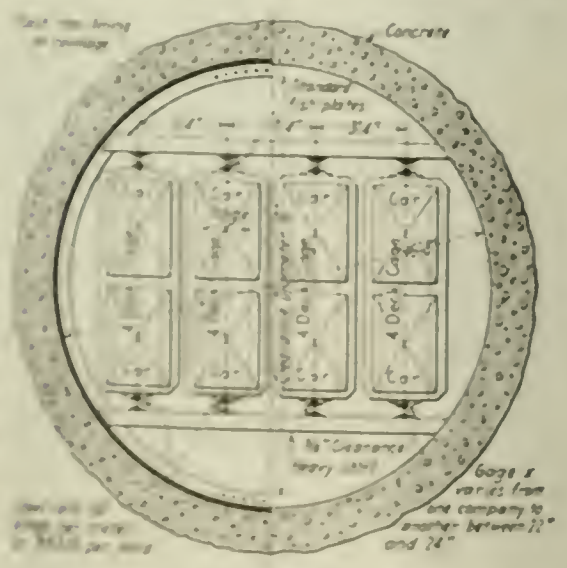
That mining men had their doubts about safety catches being effective on iron guides is proved by a certain amount of literature that found its way into the publications of the Mining Engineering Society. However, it was soon demonstrated by tests that various use

only stopped a cage more promptly on iron guides than on wooden ones, but did it without damaging them. The same kind of catches, acting on wooden rails, always slipped down on them for quite a number of feet, furrowing them terribly and making them unfit for further use.

TESTS PROVE STEEL GUIDES MORE EFFECTIVE THAN WOOD

During the seventies, when steel rails became available on the continent, they were employed as guides in preference to iron; and it was then very promptly and conclusively demonstrated that all the types of safety catches in use were as effective on steel as on iron.

In the accompanying sketch (Fig. 1) I have shown how steel guides were



Cross-Section of Belgian Shaft Showing Steel Guides

sometimes installed in deep shafts, at the time when I gained my mining experience in Belgium, in the early nineties. The drawing is made from memory and the dimensions given are the only ones I am able to remember definitely.

HEAVIEST RAILS USED FOR GUIDES

In 1890, shafts 3,000 ft. deep were quite numerous in Belgium; and there were a few, in regular operation, at

Modern Belgian Shaft in the Campine Region

depths much greater than this. All of these were provided with steel guides and steel buntons. Nothing but the heaviest rails procurable were employed. The 50-kilog.-per-meter rail (99.3 lb. per yd.) has been manufactured continuously in Belgium ever since the late eighties.

The buntons shown in Fig. 1 were, I think, 30-cm. (12-in.) channels. I am certain they were not less than 25 cm. (10 in.). There was nothing cheap about such work. There could not be, considering the speed with which hoisting had to be done, in order to reach outputs of 800 or 900 tons, in eight hours, from shafts 2,500 or 3,000 ft. deep. Hoisting speeds of 10 m. (about 33 ft.) a second were then reached. Today, they hoist at speeds even greater than this, say 19 m. (about 61 ft.) a second being often maintained during 65 per cent of the hoisting operation.

DETAILS OF A MODERN SHAFT IN THE BELGIAN CAMPINE REGION

In Fig. 2 I have shown how a modern Belgian coal shaft is equipped. The example I have selected here is a shaft in the Campine region. I was in that shaft recently. There are two pairs of four-deck cages and two hoisting engines. Each cage-deck carries two cars. The dimensions given are the only ones I have noted, besides the following data:

This shaft is 2,350 ft. deep. The eight cars hoisted in a cage contain a total of 4.8 gross tons of coal. The cars themselves together weigh 2.4 tons. A cage weighs 4.5 tons. The rope hanging in the shaft weighs 6.6 tons. The total weight hoisted is, therefore, 18.3 gross tons.

As is usual in Belgium, this shaft is lined with cast iron, besides being concreted all around as indicated in the figure. The cast-iron lining, in this case, is 220 m. high (700 ft.), because of a corresponding thickness of quicksand which had to be frozen before the shaft could be sunk. The same sinking process has been used for all the shafts of the Campine region, on account of this quicksand formation, which is nearly constant over that part of Belgium.

While I was there, the double hoisting outfit, shown in Fig. 2, made seventy-six hoists, bringing to the surface 608 cars and 364 tons of coal in one hour, from a depth of 2,350 ft. I was told that this was less than the record, which then stood at 5,056 cars and 3,034 tons of coal, in a day of eight hours; or at the rate of 632 cars and 379 tons of coal per hour.

New York City. F. C. CORNET.

Driving Wide Rooms

Loading contest shows record output, per man, per day—Influence of width of rooms on output — Discussion asked.

IN THE issue of *Coal Age*, Aug. 10, p. 216, is given an account of the results of a loading contest that took place between two mines of the Standard Island Creek Coal Co., located at Cora and Taplin, W. Va., respectively.

The account gives the average daily output of two men, working at these

respective mines, as being 50.5 tons of coal, per shift, in the one case, and 45.9 tons, per shift, in the other; or, practically, the capacity of a 50-ton railroad car, per day, for each man.

This is a record output for a miner working in 4-ft. coal and drilling, shooting and loading his own coal without assistance. It is stated that one of these men was working in a double-track room, 36 ft. wide, while the other was driving two places, each 18 ft. wide.

Reading this account interested me, particularly as I have lately been endeavoring to convince our foreman at Coral, Indiana County, Pa., that he should widen his rooms from 20 to 36 or 40 ft., believing as I do that this would increase the daily tonnage, per man.

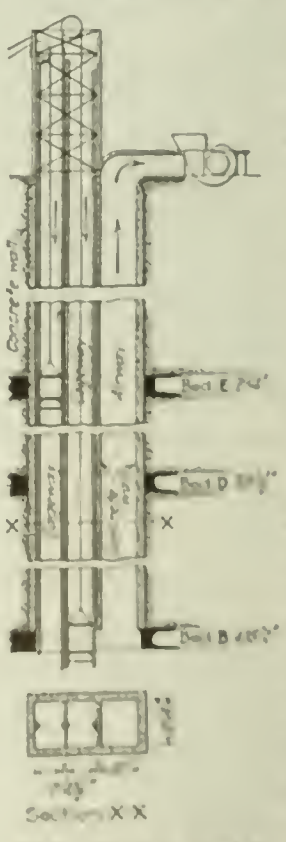
We are working coal 78 in. thick and overlaid with from 200 to 390 ft of cover. The seam which is the upper Freeport seam and is very soft, consists of 26 in. of top coal and 42 in. of bottom coal, separated by 10 in. of binder. The roof is mostly sandrock and taking the mine as a whole, it is considered very good. Occasionally, we strike a "cutter," where the roof will cut or shear from 3 to 10 ft. The floor of the seam is solid and very regular.

I would like to have the question discussed as to what influence, if any, the width of rooms have on the possible daily output, per man. It would be interesting to hear from some of the men of the Standard Island Creek Coal Co., on this question, giving their roof conditions and other data that would bear on the subject.

L. F. KLINGENSMITH,
Potter Coal & Coke Co.
Greensburg, Pa.

Inquiries Of General Interest

Triple-Compartment Hoisting and Airshaft



Double Compartment Hoistway and Airshaft Combined—Effect of Movement of Cages on Circulation of Air—Suggestions Regarding Design of Shaft and Its Equipment

HAVING in contemplation the sinking of an airshaft, at a point some distance in advance of our present workings and desiring to design and equip this shaft in a manner that it can be used as the main hoisting shaft, at some later time when the underground development has proceeded to an extent to make that advisable, we solicit the advice of *Coal Age* and its practical readers, in hopes of gaining information that will enable us to avoid mistakes that might otherwise be made.

In order to make clear the situation, I have prepared the accompanying sketch showing the cross-section of the proposed shaft, and outlining the headframe and hoisting sheaves above the shaft, together with the fan and fan drift connecting with the air compartment of the shaft. Below the sectional elevation is shown a plan of the shaft with its three compartments, comprising two hoistways for the cages and an air compartment in one end of the shaft.

As indicated by the arrows, the two hoistways are made the downcast and the air compartment is then the upcast for the mine, the fan being operated as an exhaust fan. In accordance with our best practice, the fan is set back from the shaft a short distance, as a safeguard against its possible destruction by the blast of an explosion, should one occur in the mine.

The shaft is to be lined with concrete throughout its entire depth and a 12-in., reinforced concrete curtain wall will separate the air compartment from the hoistway adjoining it. This curtain wall will extend from the top to the bottom of the shaft, thus providing separate intake and return airways in the shaft.

SECTIONAL PLAN AND ELEVATION OF SHAFT

It is assumed that the ultimate quantity of air circulating in the mine and passing through this shaft will be 200,000 cu.ft. per min. It is the intention to operate the cages at a maximum speed of 900 ft. per min. Briefly stated, this shaft will serve the following purposes: 1. Ventilation. 2. Hoisting and lowering men and supplies, and hoisting coal and rock from the mine.

As shown in the sketch, there are three beds of coal cut by the shaft; namely, beds, *B*, *D* and *E*. Hoisting operations will include the following: (a) Lowering supplies from the surface to the several levels, *E*, *D*, *B*. (b) Hoisting coal and rock from bed *B* to the surface. (c) Lowering coal from the two upper levels to bed *B*. (d) Hoisting and lowering men working in the several levels.

Having made this explanation, I would like to ask three questions, as follows: What effect will the presence of one of the cages at either of the upper levels have on the circulation of air in the hoisting compartment? 2. What effect will the travel of the cages up and down the shaft have on the air in the hoisting compartment? 3. What suggestion has any one to offer in the matter of design of the shaft, with a view to realizing the most satisfactory result from a ventilating standpoint?

It should be further stated that of the 200,000 cu.ft. of air, which is the proposed maximum circulation that will pass through the shaft, 150,000 cu.ft. will be required in the lowermost seam, Bed *B*, while the remaining 50,000 cu.ft. will circulate in the two upper levels, Beds *D* and *E*. I trust that this will make the proposition clear to all and hope for many good suggestions.

———, Pa. Chief Engineer.

This is an interesting proposition that we are glad to present to the practical readers of *Coal Age*, knowing that they will respond by giving many helpful suggestions respecting the design and equipment of this shaft, having in view the most economical and satisfactory results in its operation. By way of opening the discussion, we offer the following brief suggestions:

First, it is not assumed that this shaft is sunk so far in advance of the present working face in the old mine, but that connection with those workings will quickly provide a way of escape in case of accident in the new shaft, which would be necessary to comply with the Pennsylvania mine law.

While it is a common practice to sink a triple-compartment shaft, providing a double-compartment hoistway and airshaft combined in one there are serious objections to this plan. First, and chief of all, is the fact that an accident occurring in the shaft endangers the circulation of air in the mine.

It is true that, in this case, a 12-in., reinforced-concrete curtain wall separates the airway from the hoistways. But it is a question whether this curtain wall would withstand the terrible force of an explosion in the mine should one occur. In our judgment, a far better arrangement would be to sink two separate shafts, making one a hoisting shaft and using the other exclusively as an airshaft and escapeway in the later operation of the mine.

Answering the question regarding the effect on the air due to one cage being at the upper level and practically closing that compartment of the shaft to the free passage of air, or the effect on the air due to the travel of the two cages up and down the shaft, our experience has been that neither of these conditions have any very material effect

of each cage, however, should be built so as to permit the passage of air through them and the cages should not fit tight in the shaft, but a clearance of 3 in. at each end and 6 or 8 in. on each side of each cage should be provided.

In order to obtain the required division of the main air current, regulators will have to be placed in the two upper seams *D* and *E*, which would naturally take the larger proportion of the air, unless the current is thus restricted in them. We hope this question will be fully discussed from every angle by readers of *Coal Age*.

Examination Questions Answered

Kentucky Mine Foremen's Examination. Lexington, May 30, 1922

(*Selected Second-Class Questions*)

QUESTION—*Explain how natural ventilation in a mine is affected by the change of seasons.*

ANSWER—In the winter season, the outside temperature is generally lower than that of the mine and the cooler intake air, being heavier than the warm return current, an air column is produced that assists the circulation of the air produced by the ventilator.

Again, in the summer season, the outside temperature is generally higher than that of the mine. The result is, then, that the warmer intake air, being lighter than that of the mine, an air column is produced that opposes the circulation produced by the fan.

In general, therefore, a mine is more easily ventilated in the winter than in the summer season.

QUESTION—*What method would you adopt to have a continuous flow of air past the face of each working place?*

ANSWER—In the first place, a reliable means of producing the circulation of air in the mine must be adopted. Again, the air must be carried forward by means of well built stoppings, doors, air bridges and brattices, so that it will be made to sweep the face of the coal, in each working place. Frequent inspection of these appliances is necessary to keep them in good condition, such as to insure a continuous flow of air in the workings.

QUESTION—*What are the general requirements in regard to the distribution of air in mines, and what must be done when the current is seriously interrupted?*

ANSWER—The main intake air current must be divided into two or more splits, and the quantity of air passing in each split must be proportioned to the need therein. The number of splits must be sufficient to comply with the requirements of the mining law, so that the number of men working on a single split will not exceed what the law allows.

Should the air current be seriously interrupted, the men must be promptly notified and withdrawn from the mine. They must not be permitted to return, until the trouble has been removed and the mine examined and found safe for work.

QUESTION—*If the velocity of an air current is 725 ft. per min., in an airway 6½ x 8½ ft., what is the quantity of air passing per minute?*

ANSWER—The sectional area of this airway is $6.5 \times 8.5 = 55.25$ sq.ft. The quantity of air passing is then $725 \times 55.25 = 40{,}056+$ cu.ft. per min.

QUESTION—*Find the ventilating pressure in a mine when the downcast temperature is 60 deg. F., and the upcast 200 deg. F., the barometer being 30 in. The depth of both shafts is 300 ft.*

ANSWER—The weight of 1 cu.ft. of air in the downcast shaft is

$$\frac{1.3273 \times 30}{460 + 60} = 0.07657 \text{ lb.}$$

Likewise, the weight of 1 cu.ft. of air in the upcast shaft is

$$\frac{1.3273 \times 30}{460 + 200} = 0.06033 \text{ lb.}$$

Therefore, the difference of pressure, for a single foot of depth in this shaft is $0.07657 - 0.06033 = 0.01624$ lb. The depth of both shafts being 300 ft., the unit of ventilating pressure, in this case, is $300 \times 0.01624 = 4.872$ lb. per sq.ft. To find the ventilating pressure, or the pressure producing circulation in this mine, it would be necessary to know the sectional area of the airway, which is not given.

QUESTION—*What is meant by absolute pressure?*

ANSWER—The term "absolute pressure" describes the total pressure exerted on the air, which includes the atmospheric pressure (14.7 lb. per sq.in., sea level) and any additional pressure due a ventilator. The latter may be either positive or negative, according as the fan is blowing or exhausting air from the mine.

QUESTION—(*a*) *What is meant by ventilating pressure, in mine ventilation?* (*b*) *What is the unit of ventilating pressure?*

ANSWER—(a) The ventilating pressure, in mine ventilation, is the total pressure producing the circulation of air, in a mine. It is equal to the mine resistance, and is the difference of pressure between the intake and return airways.

(b) The unit of ventilating pressure is the pressure per square foot of sectional area in the airway or fan drift. It is found by dividing the ventilating pressure or mine resistance by the number of square feet in the sectional area of the airway. While the ventilating pressure is expressed in pounds, the unit of ventilating pressure is expressed in pounds per square foot. The unit of ventilating pressure is sometimes expressed as "ounces per square inch," 1 oz. per sq.in. being equal to 9 lb. per sq.ft.

QUESTION—*Explain the difference between ventilating pressure and absolute pressure.*

ANSWER—Ventilating pressure is the difference between the pressure on the air in the intake airway of a mine and that on the return air, in the same mine. It is this difference of pressure that produces the circulation in the mine.

QUESTION—*An airway, 16.7 ft. wide and 8.9 ft. high is passing 65,000 cu.ft. of air per minute. What is the velocity of the air current?*

ANSWER—The sectional area of this airway is $16.7 \times 8.9 = 148.63$ sq.ft. The velocity of the air current is then $65{,}000 \div 148.63 = 437.3$ ft. per min.

QUESTION—*If powder smoke requires 2 min. and 17 sec. to travel 149 yd., in an airway 10 x 12 ft. in section, what quantity of air is passing in the airway?*

ANSWER—The time, 2 min. 17 sec., is 137 sec.; and 149 yd. is $3 \times 149 = 447$ ft. The velocity of the air indicated by this observation is, therefore, $60(447 \div 137) = 195.76$ ft. per min. The sectional area of the airway is $10 \times 12 = 120$ sq.ft. The quantity of air passing in this airway is, therefore, $120 \times 195.76 = 23{,}491+$ cu.ft. per min.

QUESTION—*With a pressure, at sea level, of 14.7 lb. per sq.in., and the barometer 30 in., how far can you set a pump above the surface of the water, vertically, and not use rods for pumping? Show by example.*

ANSWER—The theoretical height of water column supported by an air pressure of 14.7 lb. per sq.in. is, $14.7 \div 0.434 =$ say, 34 ft. Owing to friction and leakage of valves, it is safe pumping practice to make the vertical height of the pump, above the surface of the water in the sump, not to exceed nine-tenths of the barometric pressure; or, in this case, $0.9 \times 30 = 27$ ft.

Seven-Hour Day Causes Increase of £30,000,000 a Year In Production Cost of British Coal

By C. H. S. Tupholme

A great deal of publicity has been given to the subject of miners' wages in Great Britain. There are other branches of productive activity in Great Britain, however, in which unemployment and short time are so prevalent and earnings so low that a great percentage of employees are compelled to subsist for long periods on the "dole." The latest official figures show that in such great industries as iron and steel, shipbuilding, and engineering, unemployment is much greater and employment itself more broken and irregular than in the coal-mining industry.

In considering the position of the British miner it is necessary to realize that even in these days of industrial depression he enjoys privileges denied to other workers. Relatively his lot is little worse—in some cases it is distinctly better—than that of workers in certain other trades —railwaymen and municipal workers excluded.

It is a popular assumption that miners are in receipt of wages only 20 per cent above those paid up to the period immediately preceding the war. This is a misconception. The average earnings of miners throughout the country work out at approximately 45 per cent more than the pre-war scale. Piece workers are allowed 14 per cent more than their old rates to enable them to earn as much in a working day of seven hours as they formerly did in one of eight. The miner also is privileged in respect to housing and fuel. At a time when accommodation is still difficult to obtain many miners pay nothing for their dwellings, or receive an allowance in lieu of rent. House coal, which is a fairly substantial item in the miners' domestic economy, is given to them either free of charge or at a price which little more than covers the cost of cartage. These two items have to be taken into account in considering the miner's position in comparison with that of his co-workers in other callings.

Leaders Allege That Miners' Earnings Are Too Low

The miners' leaders fully recognize that wages absorb the vast bulk of the proceeds from the industry, leaving the owners with a profit much less than the minimum provided for them in the terms of settlement of June, 1921. Nevertheless they persist in the claim that the earnings of the mine workers are below the "subsistence level" and need augmentation.

They now propose that the owners so raise prices to the general body of consumers as to provide a sufficient revenue from the sale of coal to afford the miners what they deem a living wage. This can only mean that there be some sort of selling combination by which coal prices shall be maintained at an artificial level. The principle is one diametrically opposed to the present methods and to the traditions of the mining industry, which before the war provided cheap as well as abundant coal. In other words, it is proposed to substitute for healthy competition a system of trustification entirely alien to the traditions of British commerce.

This expedient is likely to find little favor in the eyes of the consumer. It is directed to the same end as the proposal for a government subsidy—viz., the placing of a further burden on the community to extract an uneconomically high wage for the miner at a time when every section of the public is handicapped by high prices and overtaxation. The principle is vicious, since it is certain that if it were once admitted its application would be invoked by all other workers who considered themselves inadequately remunerated. But it is not the domestic consumer alone who would be affected by such a scheme. The great staple industries of the country—iron and steel, engineering, textiles and the railways—in paying more for their coal would find their working costs so increased as to necessitate restricted operations. The cost of living would again bound up, trade depression would become intensified, and there would be a great increase in unemployment.

One of the most serious effects of any arbitrary regulation of selling prices would be the crippling of overseas trade. The coal industry experienced the disastrous effects of foreign competition during and immediately subsequent to the period of coal control. If an artificial price is to be substituted for the open market price in international trade, nothing is more certain than the re-entry of competitors, and much, if not all, of the good effected during the past twelve or fifteen months will be undone.

It is vital that the industry should not carry a personnel in excess of its strict requirements, while it is equally necessary that every man employed should do a fair day's work. The introduction of the seven-hour day at a time when a return from artificial to economic conditions was foreshadowed was a measure which could not have been recommended had its advocates foreseen results. During this period of bad trade and uneasy markets, co-operation and solid, hard work have been more necessary than at any time in the annals of the coal trade.

The statutory reduction of working hours has had the effect of increasing the costs of production to an extent which has left its mark on the whole trade. This measure has necessitated the employment of large numbers of extra day-workers, and at the same time it has added to the cost of piece work in wages by 14 per cent. Wallace Thorneycroft and other authorities upon coal-mining matters variously estimate the increased production cost due to the act at from 2s. to 2s. 6d. per ton. At the present rate of output this saving would produce about £30,000,000 in a twelve-month, of which 83 per cent would be available as a supplement to mine workers' wages under the terms of the existing agreement.

While the relations existing between the mine owners and their work people are by no means unsatisfactory, it is obvious that much benefit would be derived by closer co-operation between the two parties. The employers are anxious to restore the industry to economic health and feel that if the men's accredited spokesmen take the long view and join with them in their efforts to this end, the most serious obstacles would be overcome. There are some factors, such as the exchanges and conditions abroad, which are outside the control of the industry; but others are amenable to control, and if these are approached in the spirit of conciliation much can be done to make the position of the trade more tolerable.

The deliberations of the National Coal Board will have proved valuable if they merely serve to elucidate the truth that better times for the miner and the industry generally are not to be obtained by schemes which are economically unsound and socially undesirable.

U. M. W. International Board Takes Steps To Restore Kansas to Good Standing

Steps to restore the autonomy of the Kansas district, No. 14, United Mine Workers, whose charter was revoked more than a year ago after district officers and a number of members of the district had been expelled from the union, have been taken by the International board of the Mine Workers, which is in session in Indianapolis. A convention of the Kansas district members has been called for Pittsburg, Kan., Oct. 25.

A constitution for the district will be drawn up at the convention and arrangements made for an election of district officers to take the place of the others. The question of reinstatement to membership in the union of Alex Howat and other officers and members of the district who were expelled from the union is to be considered separately. The charter of the Kansas district was revoked and Howat expelled after he had called strikes in violation of contracts

Federal Coal Commission Names Hammond Chairman And Proceeds to Map Out Program

By Paul Wooton
Washington Correspondent of *Coal Age*

The first act of the United States Coal Commission at its initial meeting, Oct. 18, was to designate John Hays Hammond as its chairman. The commission immediately plunged into a discussion of a program for its work. No formal announcement has been made as to how the work will proceed, but certain of its policies already are apparent. It is the intention of the commission to keep the public informed as to each step of its progress. It recognizes that in this way the public will be able to absorb more knowledge as to the problems of the coal industry. The commission recognizes that the only chance that it has to accomplish anything is to obtain public support for its recommendations. It is believed that if the public mind goes through the same processes that the minds of the commissioners will go through, they will be prepared to pass intelligent judgment on the conclusions. Frequently when conclusions constitute the first knowledge that the public has, much time must elapse before their real purport is understood. Thinking takes time. Recognizing that fact, the commission hopes to be able to carry the public along with it as the study progresses.

Lewis Invited to Informal Conference

The problem is so intricate that the commission expects to call to its aid each subdivision of the coal industry. One of its first acts was to invite into informal conference John L. Lewis, president of the United Mine Workers of America; Alfred M. Ogle, president of the National Coal Association, and S. D. Warriner, a leading anthracite operator, and to ask each to appoint a consulting committee, which is to maintain close contact with the commission and assist it by presenting such facts as may be called for from time to time.

Since E. E. Hunt is secretary of the commission, it is reasonable to suppose that he will resort to much the same form of organization that functioned so successfully during the President's unemployment conference—the plan also used at the conference on limitation of armament. At those conferences advisory committees composed of representatives of the varied interests concerned were used with great success. For instance, an advisory committee on storage would be composed of representatives of coal operators and of large consumers—those most likely to benefit or be interested in storage. This plan, if acceptable to the present commission, would be carried out in such a way that an advisory committee would be formed for each of the important problems within the industry. In this way the commission would be saved a large amount of work and would be furnished with much predigested material.

Since the commission must make its preliminary report on Jan. 15, advantage must be taken of all means to expedite the study. It is probable that the commission will call upon those most concerned to lend it some of their specialists. Only in this way can the commission procure the requisite skill necessary to its work.

Now that the commission is in action an opportunity has been given to judge as to its capability and as to the ability of the individual members to work together. The first sessions indicated that President Harding's mixture of two engineers, two lawyers, two economists, and a newspaper man is less discordant than some critics might expect. Apparently they will work well together. Judge Alschuler gave early evidence that he is experienced not only in weighing evidence but, as shown too in his packing-house experience, is skilled in obtaining evidence for himself.

Mr. Marshall is so well known for his quaint philosophy and his Hoosier directness that sight frequently is lost of the very practical way in which he reasons on problems which come before him. It already is apparent that any policy to win his support must be 100 per cent American. One of his acid tests is whether or not a man puts his American citizenship first.

Dr. Smith brings to the commission not only his own large store of knowledge acquired from having kept abreast with the coal situation day by day for a long period of years but his knowledge of the federal machinery and his acquaintanceship with the government personnel in Washington has made it possible quickly to co-ordinate the commission's work with the coal activities of the various federal departments. This is in direct contrast with the experience of numerous new boards and commissions, where there has been an exasperating loss of time before actual work could start.

Mr. Howell has a wide acquaintance with men and has an accurate knowledge as to the part coal plays in the industrial South. He has demonstrated a keen appreciation of the public's equity in coal.

No one could approach a task better prepared to serve efficiently than Mr. Neill. It has been just twenty years since he began his work with the Roosevelt Anthracite Commission. His connection with the anthracite industry has been almost continuous since. He also brings to the commission a knowledge of transportation, but above all he has a sympathetic understanding of each side of labor disputes.

Mr. Hammond, in addition to his understanding of the engineering phases of the inquiry, has a genius for organization which he is applying actively to the plan for the commission's staff.

An analysis of editorial comment in more than one hundred newspapers reveals that the *New York Call*, a socialist organ, is the only one commenting unfavorably on the personnel selected for the commission.

E. E. Hunt, Coal Commission's Secretary, Has Had Broad Economic Experience

E. E. Hunt, of Springfield, Ohio, has been selected as secretary of the President's coal commission. Mr. Hunt has been in charge of the study of intermittency in the coal industry which the Department of Commerce has been pursuing since last March. For the purposes of that study a sizable contribution was received from the Cabot fund. The study was an outcome of the unemployment conference, of which Mr. Hunt was secretary. Mr. Hunt had been associated with Mr. Hoover throughout the preparation of the report on waste in industry.

E. E. HUNT
Secretary, U. S. Coal Commission

Mr. Hunt was graduated from Harvard in 1910. From 1910 to 1914 he did editorial management work. With the outbreak of the war in Europe he was sent to Antwerp by the Committee for Relief in Belgium. He was in charge of the entire Antwerp district, in which he supervised the work connected with feeding and providing fuel

economics of the industry, but its technical data will be gladly and freely placed at the disposal of the commission.

"The Geological Survey has followed two general lines in its coal investigation under each of which a score or more of topics might be enumerated:

"(1) The extent and location of the underground reserves of coal, including the segregation and valuation of the public coal lands in the West. This appraisal of our national wealth in coal is a continuing project in which additional work is done each year.

"(2) The business of mining and marketing coal. The Survey's annual reports on coal production furnish a forty-year history of the industry, including not only statistics of production but also information on trend of size of mines and of companies, mine capacity, men employed and days worked, mining methods, prices and disposition of product.

"These records are not merely a statistical history of the industry. Each annual report contains extended comment by an observer devoting his entire time to the industry, on the economics of production and distribution. The important facts as to labor controversies, consolidations, changes in methods of mining and fluctuations of demand and supply are there referred to. The coal specialists of the Survey have been associated with the outstanding events in the industry throughout that period. E. W. Parker, in charge of coal statistics in 1902, was made a member of the Roosevelt Anthracite Commission. His successor, C. E. Lesher, was adviser to the Peabody Committee on Coal Production, and later chief statistician for the Fuel Administration. In fact the files of the Fuel Administration were turned over to the Interior Department and the coal specialists of the Survey are perhaps more familiar than anyone else available with the material in those files which bears upon the Commission's work. Statisticians of the Survey have been in attendance at the several investigations made by committees of the House and Senate in recent years and are familiar with the evidence presented at those hearings.

"For the past seven months the Survey has co-operated with the conference on unemployment in the preparation of statistics bearing on intermittent operation. The preparation of these exhibits, based largely on Survey records, has been in charge of F. G. Tryon, the present coal statistician of the Survey. I understand that the records will be turned over by the Secretary of Commerce to the Coal Commission.

"The technical and clerical staff which has built up all these records will be perhaps of more value to the commission than the records themselves. The staff have had years of experience in investigations of the coal industry and with their auxiliary equipment of mailing lists and computing and tabulating machines they may be of assistance in carrying forward new studies needed by the commission. The experienced clerical workers of the coal statistical unit were used as the nucleus around which the Fuel Administration built up its extensive statistical service.

"Closely co-ordinated with the Survey's work on coal is the corresponding work on coke, manufactured gas, natural gas, petroleum and electric power. The annual and current reports on production of these fuels and electric power and the special investigations made from time to time, such as the recent superpower survey, have furnished a body of material on the supply and demand of heat and power which the commission may wish to consult in weighing the place of coal in our national life."

Seven Injured by Slate Fall in Mine at Brownsville. Pa.; Three May Die

Seven men were injured, three probably fatally, in a fall of slate Oct. 10 in the Maxwell mine of the H. C. Frick Coke Co., near Brownsville, Pa. Pinned under the débris of the first fall, the seven men were helpless when a heavier second fall of slate enveloped them.

The seriously injured are Dewey Rankin, mine foreman; Steve Ritsky, assistant mine foreman, and Edward Queen, all of whom may die as a result of their injuries. Others injured are Peter M'Kenna, Fred Reynolds and two unidentified foreigners.

In a short time the men were dug from beneath the slate and carried to the surface.

A Public Policy for the Coal Industry*

By James A. Emery†

What does the outsider see in the coal industry today—not the prejudiced, nor the impassioned, nor the embittered, nor the merely selfish observer of your industry, but the citizen who has a sincere interest in the relationship of your great industry to the social and political problems that it is creating? During six months of deliberately suspended production he has perceived upon the one hand a solid, unified organization of workers, so powerful that it has been able to successfully resist not only economic argument but official persuasion; and on the other hand he has perceived a great industry of highly intelligent and responsible operators disintegrated and disunited, with no single responsible group or spokesman who could speak the collective thought and the collective judgment and state the collective policy of a great American industry!

Does that not suggest that there never was a more favorable, a more desirable, a more necessary moment in which this great industry should enter upon a highly systematic, organized self-examination, self-analysis and self-declaration of policy for self-government?

All the forms of government that we have had any experience with in this world must live under restraint and authority, and they either take that authority from without or they impose it from within; and the difference between popular and autocratic institutions is that the one finds its rule imposed upon the outside and the other imposes its rule upon itself by voluntary self-restraint established from within. Doesn't the coal industry need today a scientific, self-examination of its own facts?

It is essentially in the public interest that the control of private property shall be preserved within the limits of public interest; and these change with the intensity and complexity of public life, because government is no longer a mere maintainer of order. It must, under the circumstances of modern life, undertake to carry out production and distribution against arbitrary interruption, and these high obligations have fallen upon it with an intensing degree of necessity.

Appointment of Commission Due to Public Opinion

The public view of this thing, as I see it today, has been very fairly expressed in the appointment of a so-called fact-finding commission. My only anxiety is whether it will discover the facts or whether it will merely paint a picture of its theories. But no industry is so well fortified to meet the facts of life today as the one that knows itself, and by a critical examination is prepared to present, as occasion arises, an accurate picture of its own operation. And that is what American industries have been doing.

I would venture to urge upon the coal industry (to urge not only in its own interest but in the interest of the public as well, that ultimately will be the terrible sufferer if a public policy is established for the coal industry that does not correspond with the facts) the establishment of a public policy based upon facts. There is nothing that the American people have paid so terrible a price for, or have suffered for so much in the past ten years of their life, as the substitution of political answers for economic answers to economic questions. And no policy will succeed with the coal industry that is not predicated upon its facts.

First of all the coal industry cannot do better at this time, cannot fortify itself more successfully, than to undertake to organize for its own self-examination in the determination of facts with respect to itself. Until it knows itself, it cannot relate itself to others. And, secondly, it is for it to establish its public relations. I mean by that not only to make itself known as it is to the public, but to make itself known as it is to the public's representatives.

It is an easy matter to "cuss" Congress; we all do it, and then we rest ourselves by "cussing" the state legislatures or the local Board of Aldermen. But representative government is a mirror in which we reflect ourselves, because it not only pictures our virtues but it very accurately defines our defects—and the besetting sin of American business has been indifference to politics. God help the man who says that business ought to keep out of politics. Business ought to get into politics, because if this nation is going to endure it isn't going to have its policies determined by a mob, but it is going to continue to be what its founders believed it would be: an aristocracy of intelligence and character, directing a democracy of right and opportunity!

Who can organize and give direction to a public policy for the coal industry better than the men who know it? They will be listened to exactly in proportion to the breadth of enlightened selfishness with which they commend themselves to public attention. Remember, that if you don't sit in the saddle to correct evil and guide the horse of reform, there are many willing riders who think they can ride the beast better than you can.

The country has suffered from the social advice of gentlemen who could not fill pulpits to the satisfaction of a congregation. It has been advised on employment relations by men who never hired a domestic servant except in their wife's name. It has had great public policies established for it by gentlemen who had no responsibility for their utterance except the price of their lecture.

A people like ours, gentlemen, will live when we meet our public responsibility and take upon ourselves the responsibility to honestly perceive and undertake to accurately define, first, our obligations, and then I say with equal sincerity, and determination to assert and enforce our rights.

Advises Frank Facing of Employment Relations

I believe that with the coal industry demonstrating its sincere interest in the public welfare, it is in a position to present to the public, and its representatives, through self-organization and self-examination, an accurate picture of what it is and what its relationship to the public ought to be. But, gentlemen, I don't believe that we will ever accomplish for the coal industry what we hope to see accomplished—to preserve it from not only incompetent and unwise but invalid regulation—unless the industry is ready in an organized way to frankly face the problem of its own employment relations. I say that it faces invalid regulation. Why, I think that the field of coal regulation today is the last great battleground of local self-government, as opposed to overwhelming federal control.

The people of the United States have had ample warning of the situation that was bound to develop in the coal industry. Year after year the danger signs were lifted in the public sight, and year after year an indifferent and apathetic people refused to heed them. And now we come to emergencies, and emergencies always excite government under popular pressure to extreme exercise of unusual power. The neglect to establish social controls in the public interest, that would insure the protection of public right, protected in the person of private agents performing a semi-public service, has led us to the situation in which we are today, but not without considerable assistance from within the industry itself.

Nobody can read the history of employment relations in the coal industry, as spread upon the records of the courts of the United States, without perceiving that sometimes found the miners' union at times a convenient means of equalizing what it termed competition. You will recall that Aesop wrote a fable about the fox who lost his tail, and having lost it he spent a good deal of time in persuading other foxes that a tail was a useless appendage. And there have been operators who, suffering under union control and domination, have not only undertaken to persuade others that they needed it and didn't need the freedom that they enjoyed, but encouraged the union, without realizing what it was they were encouraging.

Today the field of employment relations in the coal industry represents a condition that threatens the economic

*Abstract of address before American Mining Congress, Cleveland, Oct. 11, 1922.

†Chief counsel American Manufacturers' Association

and social security of the United States. But when a great industry cannot adjust itself to changed economic conditions but must submit not to argument nor to reason nor to fact, but to force, it has lost control of the first function of management, and its first duty to meeting a public situation. The coal industry today knows that it is on an unreasonable basis, and it has just had demonstrated to it the fact that it cannot get out from under it.

An organization that is committed to the proposition that it deserves the full social value of its product and interprets that to mean its value less transportation is by its commitment to a public policy going to stop short of nothing but control, and that control can take two forms: One, the direct absorption of the industry, which it never expects to accomplish. The other, the political control, similar in form to that which was proposed for the railroads, in which the National Government will buy, for the high political influence of the miners' union, the possession of the mines which they, with the exertion of their political authority, will control. And yet, faced with this philosophy, knowing that they were contributing daily to the growth of a great organization, now numbering around 600,000 militant men, devoted as a principle of philosophy to the nationalization of the mines, the operator has become the recruiting sergeant for the proponents of nationalization and the collector of its funds, to be dispersed in the destruction of his own right of private property.

I think never did the call go out so strongly to American business men to recognize their great public responsibilities, and certainly never has opportunity more gracefully and yet more forcefully presented itself at the door of the coal industry to say to it, "For God's sake, gentlemen, establish the effective means of self-study, self-analysis, self-government within yourself, that you may demonstrate to the American people the realization of your responsibilities as the trustees and fuel agencies of our civilization, and having fortified yourself with the armor of fact and with the weapon of experience and information, analyzed and reduced to practical terms, proceed then, in the light of your experience, to undertake to organize your public relations with the people of the United States and with their agencies, as the effective means of providing defense for yourselves and an effective public policy to protect and promote the interest of the United States."

Surely the coal industry can and will meet the responsibilities of this hour and save us in other industries, as they save themselves, with our co-operation, our sympathy, our understanding, the hand of brotherhood extended to them, to assist them in the working out of their own problem, but calling upon them to provide the means of making co-operation good by establishing self-organization, self-control, self-direction and self-development within themselves, that in a single responsible voice or a single group voice may speak the collective thought and collective opinion of the coal industry to the American people and its representatives, not only with fairness, with breadth of mind and common understanding, but with a firmness that is determined alike to recognize its obligations and to assert, without fear of the consequences, its rights as citizens.

Municipal Departments of New York to Utilize Small Sizes of Anthracite

After a conference of the heads of municipal departments of New York City, Oct. 23, it was announced that during the coming winter the city would burn small sizes of anthracite. This will release hundreds of tons of domestic sizes of anthracite for household consumption, it was said. City Fuel Administrator Arthur A. Learoyd said that Commissioner Whalen would readvertise for bids on the substitute fuel agreed on to be used in city buildings.

IT IS HARD TO TELL what we when the world is coming to.—*Greenville Piedmont*

IF EUROPE DOESN'T WORK OR PEACE, she may be forced to rest or peace.—*Asheville Times*.

Retail Margin of Profit on Coal Fixed in Ohio Averages $1.86 Per Ton

Retail margins of profit on each ton of coal sold in Ohio, whether Ohio-mined or imported, have been fixed by Fuel Administrator Neal and approved by Governor Harry L. Davis. The average profit permitted retailers under the schedules is $1.86 and there are approximately 106 different margins fixed. This completes the first entire regulation by the state from the mine to the consumer under the emergency legislation recently enacted. Price margins are effective as of Oct. 20, giving five days for publication of notice to various dealers. The margin applies to the price at the mine plus the freight rate to the dealer's yard. The lowest retail allowance is 65c., in Gallia County, while the highest is $2.75, permitted in Cleveland. Under the new order where the customer makes his own delivery he is to have a reduction of 75c. per ton from the margins allowed.

Prices Ohio consumers must pay for West Virginia smokeless range from $9.99 to $11.34 a ton, in accordance with the official price list given out by State Fuel Administrator Neal. The prices are based on the federal maximum fair price of $6 a ton for West Virginia coal at the mines. Variance in transportation charges to Ohio points is responsible for the range. The price in Columbus is to be $10.09 to $10.29 a ton. In other cities they are: Cleveland, $10.74@$11.34; Sandusky, $10.64@$10.84; Toledo, $10.54@$10.74; Canton, $10.07@$10.84; Youngstown, $9.99@$10.94; Akron, $10.07@$10.84; Dayton, $10.39@$10.49; Marion, $10.04@$10.24.

Michigan Governor Seeks Aid of Congress To Fix Reasonable Prices at Mines

Legislation designed to regulate distribution and cost of coal and coke in Michigan having been approved by the Legislature and signed by Governor A. J. Groesbeck, the latter has arrived at the conclusion that the most direct way of holding down prices is to be found in establishing reasonable prices at the mines. He is urging the governors of various other states to join him in appealing to Congress for action to that end.

The Governor also is conferring with Conrad E. Spens, Federal Fuel Administrator, in the effort to obtain more reasonable prices on anthracite than are quoted by some of the independent operators, seeking business in Detroit with quotations of $12@$14 at the mine.

Dealers applying for licenses in Wayne County are required to report on the quantity of coal they sold last year, the amount they have sold so far this year and how long they have been in business. This information is expected to supply a basis for computing the fuel requirements of the state and for determining the eligibility of the dealer to be classed as a legitimate coal merchant.

The new Michigan law is quite similar to the legislation enacted in New York State, though the Michigan law is said to be less drastic in some of its provisions.

Coal Consumption by Utilities in August Highest of Any Month Since February

Electric public-utility plants consumed 2,814,141 net tons of coal during August, according to a recent report of the Geological Survey. This is the largest tonnage for any month since February and compares with 2,563,607 tons in July. Production of electricity in 1922 has been accomplished through steadily increasing use of fuel power, while water-power production has declined gradually from the high mark of the year attained in May.

Evidently the scarcity of coal has increased the use of oil and gas, as August saw a record-breaking output of electricity, averaging 131,100,000 kw-hr. per day, exceeding the June record by 2½ per cent and July by 5 per cent. The heavier production no doubt was due to the increase in the domestic and commercial lighting load brought about by the activity in the building industry and by the demand by industries who were forced by lack of coal to turn to public-utility plants for power.

German Coal Situation Proves Not as Bad as Pictured

By H. O. Herzog
Berlin, Germany

The annual report of the German National Coal Association, dealing with the production, evolution of prices, consumption and supply between April 1, 1921, and March 31, 1922, has just been issued. Of special interest is the balance of loss drawn after the final division of Upper Silesia. Of 75 mines which produced 43,800,000 tons in 1913 and approximately 30,000,000 tons in 1921, representing 75 per cent of the total production, 59 have gone to Poland. Measured by the production of 1913, the loss to the national wealth thus incurred is 400,000,000 gold marks per year. The actual loss of coal to the supply of the interior of Germany is, however, not so large as has been commonly stated in public, the fact that the province itself consumed the third part of the output, while another third part was exported under Entente control to surrounding countries, having more or less been kept from public attention. Actual shipments to the interior of Germany have averaged 12,000,000 tons during the last two years. The output of the mines remaining to Germany may for this year be assumed at 8,000,000 tons. Deducting therefrom the now greatly reduced local requirements, which probably will be 2,000,000 tons, 6,000,000 tons will remain for the supply of the German interior. The net loss to the latter, therefore, is only 6,000,00 tons per year.

The National Coal Association is an institution called into existence by the law of March 30, 1919, regulating the control of coal; it forms part of the organization provided for this purpose, the other members being the National Coal Commissary and the National Coal Council. The first named is the executive and the latter an advisory body, best described as a coal parliament. In this organization the Coal Association represents the producers; it is formed as a joint stock company with a nominal capital of 250,000 marks, in which the coal syndicates of the various districts and the States of Prussia and Saxony in their capacity as mine owners are shareholders. It does not transact business in the proper sense, having nothing to do with sales or distribution. Its object is the adjustment of coal prices in conjunction with the other members of the organization of control, and eventually to assume the function of the coal commissary.

Summarizes Country's Coal Situation

Although a few representatives of the labor class are sitting on its board of directors and also are represented in the board of managers, the Coal Association is more or less a combine of the producers' interests, wherein lies its chief importance as a public institution. This is reflected in the annual report of the association, which goes far beyond its actual object and is a summary on the whole coal situation.

The picture presented by a review of the production at the present rate and that of the past years is not at all hopeful. In no mining district has the pre-war average been attained, or the average of the short-handed war time been reached. The best result so far reported is that of Lower Silesia, where the output in 1921 was 84.5 per cent of that of 1913. The next best were Saxony, with 82.6 per cent, and the Ruhr district, with 81.8 per cent. The worst case is that of the Aix la Chapelle fields, with only 64.2 per cent. Upper Silesia, with 67.7 per cent, was only a trifle better. Considering that the output of 1913, upon which these figures are based, is the highest on record, these figures do not make a bad showing.

In nearly all cases, with the exception of the Aix la Chapelle district, a considerable recovery has taken place since 1919; in the Ruhr district, for instance, it was from 61.9 per cent to 81.8 per cent of the 1913 output. When, however, the means whereby this recovery has been achieved is taken into account, these figures have a sinister significance.

Over 1,000,000 men were employed in 1921 in German coal mining, including brown-coal mining, as against 660,000 in 1913. The increase of employees in bituminous-coal mining from 1913 to 1921 was no less than 263,000, or nearly 50 per cent. The output of the inside workers per hour in 1920 dropped to 116 kg. as against 136 kg. in 1913. During 1921 the average was even a trifle lower, showing a slight recovery during the first three months of this year. According to consecutive reports this recovery was only temporary. The efficiency of labor in the Ruhr district is at present about 85 per cent of pre-war standard and in Upper Silesia it is only 77 per cent. When it is considered that 840,000 men employed in coal mining produce now only 80 per cent of what 580,000 men produced in 1913, the standard of efficiency appears to be still lower or approximately only 55 per cent. Almost identical conditions prevail in brown-coal mining.

The quantity of coal at disposal for the supply of the country within the present frontiers, after deducting the Entent tribute and the compulsory export from Upper Silesia and ignoring small quantities of free export, averaged in 1921 75 per cent of that of 1913. The increased production of brown coal, amounting to 36,000,000 tons, is one of the few favorable aspects of the situation. The efficiency of brown coal has been estimated at 2/9 of that of bituminous coal, which is entirely too low, considering the progress made with brown-coal combustion. The report leaves out of discussion how the financial situation of the mines has been affected by the prevailing price policy. In touching upon the evolution of coal prices in comparison with the increase of wages and other component parts of cost and production the report leaves it to the reader to draw his own deductions.

Cost at Mines Moves Skyward

The increase of the net cost price at the mines exclusive of taxes and other levies is 49.76 times that of 1913. The cost of labor for one ton of coal during the same time has increased 51.93 times. It is interesting to note that in pre-war times the ratio between wages per shift and cost of labor per ton was 5.50 to 6.20 marks, while in April, 1922, the ratio was 177 to 322 marks. The relation has, therefore, charged from 1:1.2 to 1:1.82. Other details of production cost have increased above pre-war prices in a still larger proportion, as, for instance: Rails, 64 times; iron ties, 77 times; oil, 60 times; wire, 77 times; structural steel work, 100 times; boilers and piping, 110 times; electro-technical equipment, 65 times.

This demonstrates that the level of coal prices is maintained to a certain degree at the expense of the property of the mines, leaving them hardly any margin for renewal and extension. As a consequence the equipment is largely run down, especially in the case of coking plants.

While the National Coal Association is loyal enough in public to attribute these unfavorable circumstances to the general unfortunate situation, in private conversation bitter complaints are heard of the short-sighted price policy which prevented the accumulation of sufficient funds for renewal and extension while they were still possible. The time for such is now considered past. The only way out of the existing difficulties is the extension of the working time. Opposition of the miners to overtime has lately receded, but the concession made lately for three extra shifts of two hours each per week is, unless considered only as a start, entirely insufficient.

To sum up the situation, in 1913 Germany had a surplus of coal export over import of 14,000,000 tons; in 1921 76,500,000 tons of coal were left for the country's consumption as against 119,000,000 tons in 1913. The total deficit in the supply compared with the latter year, taking into account both bituminous and brown coal, was in 1921 38,500,000 tons, which, when added to the export surplus, shows a total loss of 73,000,000 tons. The deficit in supply has to be made up by imports as long as it is not covered by increased production. The next few months will show what

Effect of National Wage Agreement On British Coal Mines

Some interesting results of the working of the national wage agreement which has been in force in Great Britain for more than a year have recently been given out by the Mining Association, which body represents the operators in the United Kingdom.

The first quarter, Ca., immediately preceding the great stoppage, resulted in a loss to the owners of £14,684,936. This was the position when the strike began. The cost to the pits of the stoppage is estimated at a minimum of £[illegible]. The following table gives the results of colliery operation during the first year (to June, 1922) of the national agreement:

TRADING PROFITS

[illegible]	£103,872
[illegible]	484,685
[illegible]	712,065
[illegible]	918,384
[illegible]	5,504,586
[illegible]	1,325,749
[illegible]	41,609
[illegible]	22,959
[illegible]	45,810
	9,399,519

TRADING LOSSES

[illegible]	£52,349
[illegible]	141,799
[illegible]	13,618
[illegible]	17,921
[illegible]	49,344
	275,031

If the net trading profits are set off against the loss during the strike it is seen that the net loss was £1,328,962. In the corresponding period of 1913 the profits were £28,000,000.

From last November to June of this year the owners have paid out £2,500,143 to make the wages up to 20 per cent above the standard.

During the year under review the tonnage and profit or loss figures were:

	Tonnage Raised	Profit (+) or Loss (−) Total	Per Ton
[illegible]	[illegible]	+ £103,872	+ 0s 1 0d

Enginemen to Become Coal Operators

The Brotherhood of Locomotive Engineers is to enter the ranks of the coal operators, according to a statement by Albert F. Coyle, editor of the *Brotherhood of Locomotive Engineers' Journal*. "The Locomotive engineers are making a $[illegible] investment in West Virginia and Kentucky coal mines," said Mr. Coyle, "which means not only a fair deal for the miners but better and cheaper coal for the consuming public.

"The leading officers of the brotherhood have obtained control of more than 4,000 acres of the best coal land in the United States, situated on Coal River, in Boone County, West Virginia, and in Floyd County, the heart of the Big Sandy coal district, near Prestonsburg, Ky.

"The Coal River Collieries, as the new company is called, is owned by hundreds of locomotive engineers throughout the country, who have subscribed in small amounts to the capital stock of $[illegible],000,000.

"The engineers are not only going into the business of mining coal; they are also planning the establishment of retail yards to sell their coal at reasonable prices to railwaymen and other workers in the large cities. Locomotive engineers and their friends have already organized these auxiliary coal yards in Ohio and Michigan, and have placed contracts with their coal companies for delivery direct from the mine pits to consumers. It is estimated that the mines will have a capacity exceeding 6,000 tons a day."

Smokeless Output in August Exceeded That Of a Year Ago, Despite Car Shortage

Notwithstanding the handicap of a car shortage, 2,847,738 net tons of coal was produced in the four smokeless districts of West Virginia in August, according to figures just compiled. Output during the first eight months of 1922 exceeded by six and a quarter million tons that of the corresponding period of 1921. If production can be continued at the same rate during the remainder of the year, there is every prospect that 1922 will eclipse the banner production year of 1916, when 36,000,000 tons was produced.

The following is an analysis of smokeless production for August and for the eight months of the year:

AUGUST OUTPUT OF SMOKELESS COALS IN WEST VIRGINIA
(In Net Tons)

District	1922	1921	1922 Decrease	1922 Increase
Pocahontas	1,479,004	1,155,645		323,359
Winding Gulf	458,329	443,604		14,725
New River	511,990	510,200		1,790
Tug River	398,415	315,075		83,340
Totals	2,847,738	2,424,524		423,214
Totals, July	2,630,565	2,164,185		
Totals, June	3,777,558	2,869,574		
Totals, May	3,687,874	2,975,711		

The Norfolk & Western hauled 1,872,875 tons of the August output, the Virginian 432,103 tons and the Chesapeake & Ohio 542,850 tons. The total coal movement in net tons of the three roads during that month is shown in the following table:

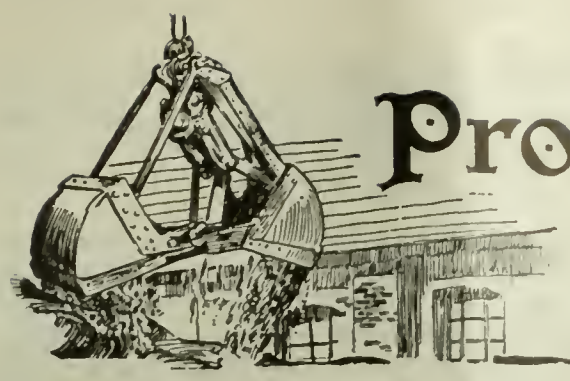
HAULED BY NORFOLK & WESTERN

Pocahontas	1,474,370	Clinch Valley	185,645
Tug River	398,415	Kenova	143,320
Thacker	570,020		
Total			2,771,820

HAULED BY CHESAPEAKE & OHIO

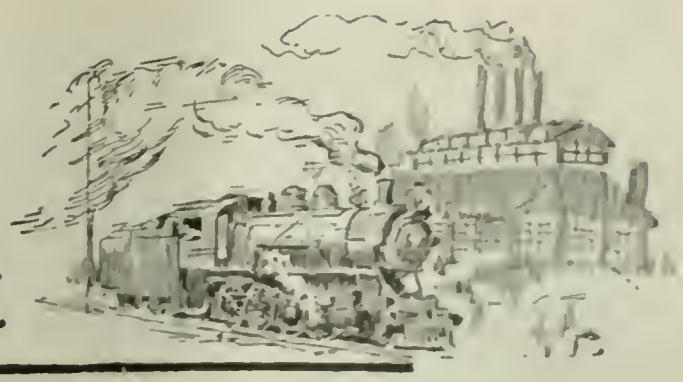
Logan	764,450	Kanawha	152,860
New River	423,060	Coal River	120,150
Winding Gulf	119,790	Kentucky	236,820
Total			1,817,150

HAULED BY VIRGINIAN RY



Winding Gulf	338,539	New River	88,930
Pocahontas	4,634	High Volatile	67,050
Total			499,153

Forty-Eight More Men Indicted for Murder In Connection with Herrin Massacre



The special grand jury at Marion, Ill., finished its work on the Herrin massacre case Monday, Oct. 23, by indicting forty-eight more men for the murder of Ignace Kubenis, a victim who died of wounds since the jury recessed last month. Circuit Judge Hartwell says the indictments are illegal because returned at a term of court subsequent to the one at which the jury was impanelled. State's Attorney Delos Duty disagrees with him.

Only a few witnesses were heard on Monday, and they are said to have told of wounds inflicted on Kubanis, and which are said to have resulted in his death. This makes 434 persons the grand jury has indicted in connection with the rioting in which twenty-three men were killed.

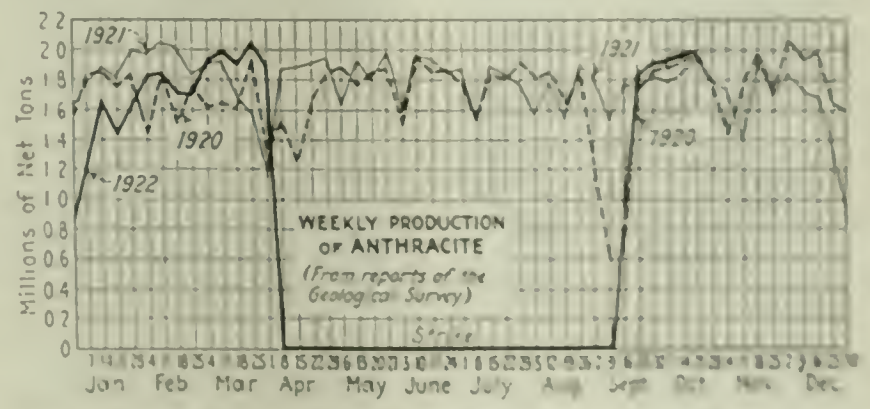
MOST MEN'S IDEA of a living wage is about two dollars more than they get.—*Portland Oregonian.*

Production and the Market

Weekly Review

Colder weather has strengthened the domestic market. Industrial buyers, however, are as yet unchanged in their attitude of aloofness. Cars are so short and the steam market so weak that the net result is a continuation of the price decline which has been in effect for the last 60 days. *Coal Age* Index of spot bituminous coal prices receded to 352 on Oct. 23, a drop of 16 points from the preceding week; the average price corresponding to this index number is $4.26—the week before it was $4.45.

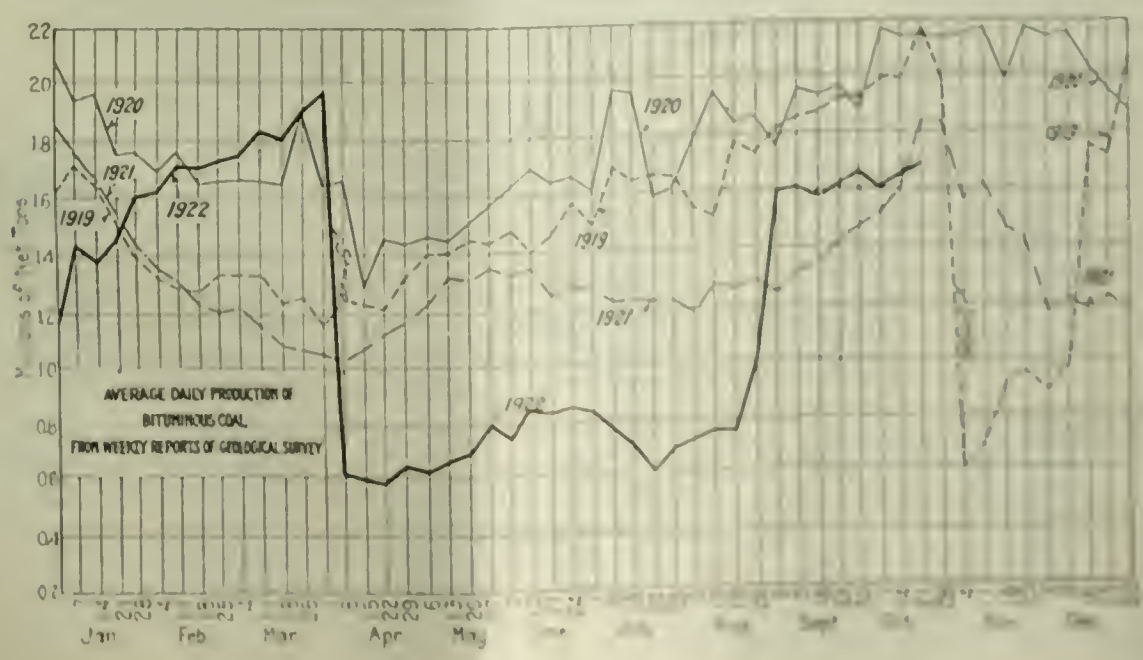
Car shortage is prevalent everywhere and poor transportation conditions make deliveries slow and uncertain, but circumstances indicate that there would be a heavy surplus of coal if the carriers were able to give better service. As it is, production is becoming more evenly balanced with current demand, and even the slight upturn in general industrial buying which has been brought about in the last ten days discloses the narrow margin between supply and demand.



Even Railroads Have Delayed Stocking

The stocking program has not yet started. Even the railroads are not building up any appreciable reserves. The feeling seems to prevail that with the end of the Lake season and more seasonable domestic weather there will be plenty of tonnage then available to care for current needs and to build stocks. Day-to-day requirements constitute the main market activity and prices show a wide range. Some coal, caught on a poor market, sells off, while on the other hand a consumer in need of coal pays the higher quotation without a murmur. There is no complaint heard about the ruling prices, nor is the consumer evincing any apprehension about the state of the market when colder weather may be expected to interfere with the movement from the mines.

New England is deaf to the offerings being made to that market. Large consumers in that territory have sufficient coal on hand to await developments in November and December. The smaller buyer is taking some additional tonnage that he has been considering since last July, but the amount is not sufficient to check the declining current quotations, whether all rail or coastwise. British coal is still a factor along the Atlantic seaboard, but receipts are falling off daily.



The Cincinnati gateway is feeling the competition of coals from outside territory and prices have softened all along the line. Eastern inland markets, however, feel the heavy drain on production made by the Lakes and railroads, and this section presents the firmest market of today. Chicago and Midwestern points are saturated with steam coals, produced in an effort to meet the onrush of domestic orders.

Anthracite domestic sizes are, of course, in heavy demand and the cold weather has brought urgent orders to the retailer. Movement still centers on the East, although Lake business is increasing. Western and

more distant points are receiving meager shipments, much of it at high independent figures.

Steam sizes are burdensome. Sales are slow and companies are running these coals to storage, while various railroad embargoes have been placed against their movement, as the congestion of these loads threatens to affect production of the much-needed family sizes.

ILLINOIS

"Complete returns on coal production in the third week of October show an increase to about 10,200,000 tons of mine coal," says the Geological Survey. "The number of cars loaded on Monday, Oct. 16, as reported by the railroads was 41,284 cars, establishing a new record for this year. On Tuesday loadings declined to 41,200 cars, and on Wednesday to 33,806. These were, however, the highest loadings reported on any second and third working days of a week since the close of the strike. On Thursday there was a further decline to 28,784 cars."

Dumpings of Lake coal were 905,130 net tons during the week ended Oct. 23, as compared with 1,090,599 tons in the preceding week. This movement has been gradually declining since it reached the peak, during the third week in September. Total movement for the season to date stands at 13,451,130 tons; during the corresponding period of 1920 it was 20,870,397 tons.

The recent heavy receipts of soft-coal cargoes has reassured the Northwest, and while domestic business is strong the steam demand has fallen off. When navigation closes, the other sources of supply will be drawn on to help out the shortage on the docks. North Dakota lignite and Montana coals in increased production can keep the Dakotas going; southern Minnesota and southern Wisconsin can use Illinois coal, and northern parts of Minnesota and Wisconsin only need be dependent on dock supplies. The utilization of the Western coals may have a lasting competitive effect on the future dock trade.

New England all-rail receipts of soft coal were 3,636 cars during the second week of October, as compared with 3,272 cars in the preceding week. A low price of $3 was offered last week to railroads in this territory, but no takers are recorded. British cargoes and coastwise fuels leave little

Same week in 1921	899,681	182,595

	Surplus Cars All Cars	Surplus Cars Coal Cars	Car Shortage	
Oct. 8, 1922	5,500	3,024	141,252	40,499
Sept. 30, 1922	5,843	3,486	130,325	38,954
Same date a year ago	142,970	82,535		

room for all-rail coal in this apathetic market, and when the present high freight rate from the mines is considered it is realized that Hampton Roads is in excellent competitive position for what little business is offering.

Hampton Roads dumpings have held around 260,000 net tons for the last three weeks. During last week 260,358 tons were dumped as compared with 262,997 tons in the preceding week. Coastwise trade has dwindled of late but

coal on hand at the piers is not gaining, as car shortage and transportation troubles have affected receipts. The stage appears set for a considerable resumption of coastwise shipments, both on spot and contract, as soon as the congestion of boats is cleared up at New England ports.

ANTHRACITE

Production of anthracite has passed the 2,000,000-ton mark. The output during the week ended Oct. 14 was 2,075,000 net tons, and early reports for last week indicate that production in that period will again be in the neighborhood of 2,000,000 tons.

All-rail shipments to New England were 3,226 cars during the second week of October, as compared with 2,759 cars in the previous week. The East has fared the best since mining was resumed, and the domestic situation, while still troublesome, shows marked improvement. Western points are taking a little coal, much of it at high independent

Coal Age Index 352, Week of Oct. 23, 1922. Average spot price for same period, $4.26. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions each of slack prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

figures. Lake dumpings during the week ended Oct. 23 were 153,553 net tons.

COKE

Beehive coke production continues its slow but steady upward trend. The output for the week ended Oct. 14 was 183,000 net tons, as compared with 173,000 tons in the preceding week. The present rate is nearly double that of a year ago, when the business depression was acute.

Connellsville prices continue to break and only an occasional purchaser is coming into the market. Softening bituminous coal prices cause coke buyers to feel that they are due for lower quotations. Pig iron is so quiet that furnaces are conservative in making arrangements for reopening.

MONTHLY OUTPUT OF BYPRODUCT AND BEEHIVE COKE IN THE UNITED STATES (a)

(Net tons)

	Byproduct Coke	Beehive Coke	Total
1917 Monthly average	1,978,000	2,194,000	4,172,000
1918 Monthly average	2,144,000	2,442,000	4,586,000
1919 Monthly average	2,001,000	1,450,000	3,451,000
1920 Monthly average	2,183,000	1,749,000	3,932,000
1921 Monthly average	1,000,000	601,000	1,601,000
June, 1922	2,000,000	400,000	2,400,000
July, 1922	2,000,000	400,000	2,400,000
Aug., 1922	1,700,000	350,000	2,050,000
Sept., 1922	2,000,000	400,000	2,400,000

(a) Excludes beehive coke made at mines not connected with byproduct plants.

Foreign Market And Export News

Continental Buyers Appear As American Orders Abate

Setback to British Producers Only Temporary—Falling Prices a Magnet—Export Situation Improves—French Markets Stronger—Wages of German Miners Raised to Boost Production

British producers received only a temporary setback when the flood of American orders abated. The drop in prices which followed immediately attracted Continental buyers, and the export situation is steadily improving, with production being maintained and prices strengthening.

French markets also are stronger. Domestic sales lead the demand. The owners have averted a mine strike by temporarily withdrawing their recent demands for an adjustment of working time. Wage increases have been granted German workers in an endeavor to speed up production.

British Prices Rise as Export Demands Increase

Great Britain is finding an active market for the Admiralty coals and prices are firm. Lower grades are in oversupply, with weakened quotations. The output during the week ended Oct. 7 was 5,200,000 gross tons, according to a cable to Coal Age. This exceeds the previous high mark established for the week ended Sept. 2 when production reached 5,201,000 tons and is 33,000 tons above the preceding week.

Operators in the north of England are optimistic. October production was sold up early in the month and sellers are only entertaining inquiries for November at full market values, and in some cases at fair advances on the present ruling prices. The demand is still mainly from Germany, though Italy and France are well in the market. Durham especially is doing good business and there have been considerable sales of coking coal for monthly deliveries over next year at 20s. per ton f.o.b., quantities ranging from 15,000 to 30,000 tons. Much of these sales are for deliveries during January and March.

Now that the peak of the United States call has passed conditions in the Welch coal trade are more unsettled, though some brightening is evident during the past two weeks owing to a revival of the European demand, as a result of which the entire British coal trade has improved. The drop in prices following the filling of American contracts has had the effect of attracting Continental buyers, especially Germany, France and Italy.

The Scottish trade is marked by a general upward trend of prices, and round sorts have advanced by as much as 2s.@2s. 6d. per ton. The chief customer is Italy, though some cargoes are still being booked to the U. S. and Canada.

The miners have threatened to strike on Nov. 5 in Wales with the object of forcing the non-unionists into the ranks of the Miners' Federation. Extensive propaganda work is to be undertaken by the Miners' Federation with the object of bringing the non-unionists into line.

Business Slumps at Hampton Roads

Business continues to lag at Hampton Roads, with coastwise trade dwindling and bunker business scarcely holding its own, in the face of continued decline in prices. Export business is practically at a standstill.

While the supply of coal on hand is large, it is distributed through the trade in such small amounts that few dealers have any considerable cargoes on hand.

The general tone of the market is dull, and little prospect of immediate revival is in sight. Dealers are hopeful, however, of better business later in the fall when shipments by rail to the West begin to lessen.

World Production of Coal in First Half of 1922

In spite of the great strike in the United States the world's production of coal in the first half of 1922 was greater than in the corresponding period of 1921. The total output in the six months, January to June, 1922, according to reports collected by the United States Geological Survey, was approximately 568,600,000 metric tons.

Continued for twelve months, this rate of output would yield a total of 1,137,000,000 tons. Settlement of the strike in this country insures that world output in the second half of the year will be greater than the first, but even so, it seems unlikely that the total for 1922 will much exceed 1,180,000,000 tons. This is an increase over 1921, but a decrease of nearly 140,000,000 tons from 1920.

PRODUCTION OF COAL IN PRINCIPAL COUNTRIES OF THE WORLD, JANUARY-JUNE, 1922

Country	Metric Tons	Per Cent of Total

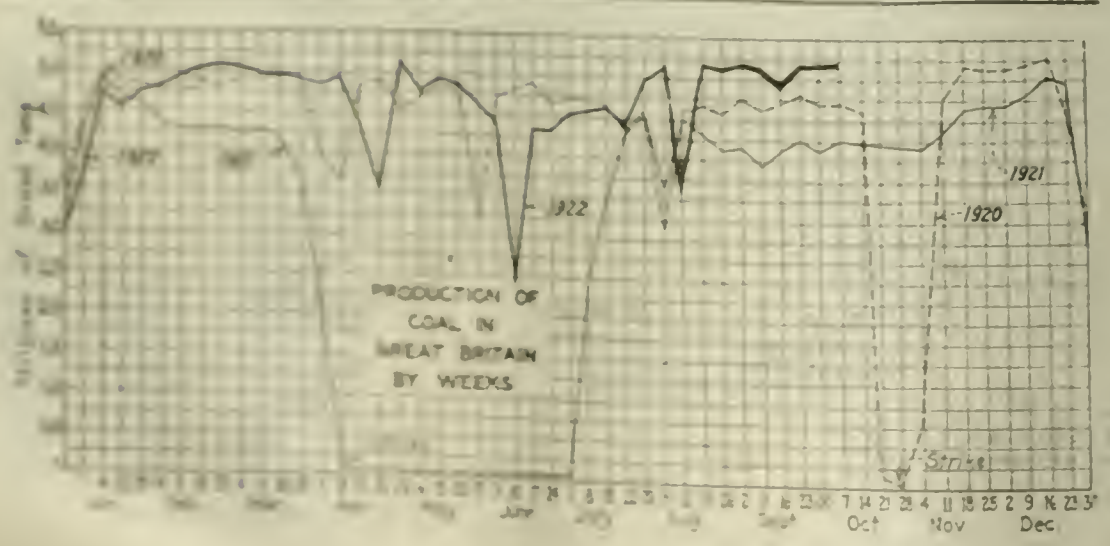
a Estimate included in total. b Includes Saar and for months January-May the entire output of Upper Silesia. c Includes 1,775,000 metric tons (estimated) produced during June in Polish Upper Silesia.



German Miners Get Wage Increase

The award conceding an increase of 150 m. per man per shift to the Ruhr miners for October has been made binding by the government, despite the owners' refusal to accept this award.

The Ministry has also decided that the wages of miners under the Rhenish Brown Coal Syndicate shall be increased to the same extent as those of the Ruhr miners, and that the increases for the other brown coal districts shall be in the following proportions of that amount: Duren district, 91 per cent; Mid-German Brown Coal Cyndicate, 92 per cent in the central district, and 90 per cent in the marginal districts; Bavaria, 94 per cent for the large pits and 90 per cent for the small concerns.

It is stated that to the end of September the Westphalian pits had not derived any advantage from the introduction of overtime at the beginning of that month, but only additional financial burdens, as only 52 per cent of the underground men have worked the additional hours. The average daily production is estimated to have increased by only 7,000 tons, or from 308,000 to 315,000 tons, whereas a daily advance of at least 30,000 tons was expected from the overtime system.

Production throughout Germany in August was 10,200,000 metric tons, as compared with 11,730,000 tons in the same month in 1921, which included 1,950,000 tons in East (now Polish) Upper Silesia. For the eight months ended with August the output amounted to 89,280,000 tons, as compared with

88,990,000 tons, including 13,890,000 tons in East Upper Silesia. Production of lignite in the eight months was 89,480,000 ton (80,550,000 tons in the corresponding period in 1921); coke 19,500,000 tons (18,490,000 tons); and lignite briquets, 19,510,000 tons (18,760,000 tons).

Production in the Ruhr region including the pits on the left bank of the Rhine, during the 26 working days of September is estimated at 8,200,000 tons as compared with 8,300,000 tons during the 27 working days of August and 7,900,000 during September, 1921.

Production of coal in the Ruhr region during the week ended Sept. 30 was 1,898,000 metric tons and in the week ended Oct. 7 it was 1,855,000 tons, according to a cable to *Coal Age*

Strike of French Miners Is Averted

There continues to be a very active demand in the Nord and Pas-de-Calais fields, both for industrial and domestic coals. The demand for the latter exceeds the supply. In the Loire field there is also a strong inquiry for house coals, but industrials are rather quiet. Lorraine and the Sarre are now in a favorable position.

The strike fears have been dispelled by a letter written on Oct. 7 by the owners of the Nord and Pas-de-Calais to the Minister of Public Works, in which the owners withdrew their previous decision to reduce the wages as from Oct. 15, if in the meantime they had not obtained sufficient relief on their cost prices. The owners state that they will continue to assume the sacrifices in favor of their men, hoping that Parliament will so amend the Act of June 24, 1919, on working time in mines, as to permit the French collieries to adequately meet the competition of foreign coals.

FRENCH CONSUMPTION STATISTICS

	August	1st 8 Mos of 1922
	—Metric Tons—	
Coal		
Production	2,665,137	20,750,635
Plus imports	1,766,670	14,733,120
	4,431,807	35,483,755

Coal Paragraphs from Foreign Lands

ITALY—The price of Cardiff steam first is quoted at 39s. 6d., according to a cable to *Coal Age*.

BELGIUM—On the coal market orders for all domestic description are numerous. Industrial sorts are also in demand and it is said that the orders received cover several months.

Production during August was 1,694,940 tons, against 1,669,290 tons in July. Stocks on Aug. 31 stood at 1,041,880 tons, as compared with 1,244,700 tons at the beginning of the month. During August, 245,040 tons of coke were produced against 227,590 tons in July, while production of briquets amounted to 216,610 tons, compared with 208,240 tons in July.

AUSTRALIA — Widespread cessation of work in the New South Wales collieries has already commenced, but the shipping community remains unperturbed. It is pointed out that there are hundreds of thousands of tons of small coal at the pit mouth, some of which has been accumulating for years

INDIA — The Bombay bunker coal market is dull. The fuel oil market shows no change.

British Owners Bear Heavy Losses

The manner in which the Wage Agreement in the coal industry operates to the advantage of the men is seen in the certificate of the joint accountants setting forth the financial results of the South Wales collieries for last July, upon which wage rates for September were determined.

It is shown that the costs of production, i. e., the miners' minimum wage, stores and timber, and other costs, swallow not merely the whole of the sum allocated to the owners as their standard profits, but an additional amount of nearly £47,000.

The result of the ascertainment for July showed an available surplus in the case of South Wales of £6,566, which, under Clause 4 of the Terms of Agreement, has to be applied to the reduction of the deficiency of £56,840, representing the cumulative deficiency of previous months. Thus, there is left a deficit of £49,914, to be carried forward as a first charge on any surplus which may accrue in subsequent periods. What the South Wales owners have actually gained is this slight reduction in the sums recoverable by them. The payment of the minimum wage provided for in Clause 8 of the Agreement has, however, mulcted them in a heavy out-of-pocket loss. The proceeds in July are such that the owners have had to forego the whole of their standard profits and pay an additional £46,989.

The total sum sacrificed by the owners since last November in South Wales now amounts to not less than £2,334,000, the whole of which has to be borne permanently by them, since under the Terms of the Agreement it is not recoverable.

Large Consumers Active; Others Buy Hand to Mouth

Despite Low Stocks and Car Scarcity, Bargain-Hunting Tactics Are Common—All but Best Coals Sell Off Under Pressure—British and Southern Fuels in Less Demand.

Buying activity is still confined to the railroads and large consumers. Others are still on a hand-to-mouth policy and many have no stocks worth mentioning. Cars are short, but these consumers refuse to worry about the situation and are employing bargain-hunting tactics to procure their current needs. Only the best coals are readily salable—the others are selling off under the pressure.

Late receipts of British coals are still offered at low figures, but with heavier home production these sellers are having a hard time to dispose of their free cargoes. Southern coals also are less in demand. Rail deliveries are slow but enough coal is moving to more than fill all current demands.

BALTIMORE

While the car supply is at present running as low as 15 and 20 per cent., and winter approaches rapidly, the coal trade here is faced by the rather unusual condition of decreasing demand. In normal times a condition of car supply such as has existed for the past two or three weeks would have jumped the price. Instead, there has been a decline of $1@$1.50.

The root of the trouble probably lies in the fact that, while these prices were nowhere near as high as they have been on several occasions since the war, they were still high enough to make some purchasers hesitate in stocking against fall and winter needs. Then came a slide in prices and instead of the lower quotations bringing an increased buying call, the buyers seemed to hold off for still lower quotations, and the very favorable prices of this time have apparently failed to satisfy them.

The light movement on the railroads is shown by the fact that fuel loaded on private cars and placed on sidings for shipment to Baltimore has in some cases been held up for three or four days because the railroads did not have sufficient coal cars loaded to make up a full train for movement to a particular terminal.

PHILADELPHIA

The claim is being freely made that the car supply in the soft coal region is at the lowest ebb it has reached since mining was resumed a little over a month ago. At this time there is an influx of assigned car orders for the loading of railroad fuel. It is believed the railroad companies have urged the issuance of these orders, as they realize better than any one else the conditions which are confronting the trade. There is no question that the roads realize that the purchase of fuel at the ruling prices is really a good buy, and they are now sharing in the production with the utility plants and other large consumers.

Prices are still easy, with just the slightest tendency toward a firmer condition. One house which has endeavored to make a survey of the field has reached the conclusion there is at this time not more than a five weeks' supply of coal on the ground in this district. This is including the stocks of the big consumers and striking an average for all. They claim to have learned of more than an occasional instance of smaller users having less than two weeks' supply on hand, and a few actually waiting for a car en route.

As yet there is no diminution in that class of consumer who prefers to wait for lower prices before trying to accumulate a surplus. It may be useless for such concerns to even try to get stock ahead quickly, as they would only succeed in running up the market.

CENTRAL PENNSYLVANIA

Prices are lower now than they have been for a long time. With the exception of the higher grades, they are below the fair prices fixed by the state fuel commission following the termination of the strike. Pools 11 and 18 are selling $3.25@$3.50. Pool 10, $3.50@$4; Pool 9, $4@$4.50, and Pools 1 and 71, $4.50@$5.

Production reached the high-water mark in the week ended Oct. 15, when loadings were 19,900 cars. The operator's associations in the district have asked the I. C. C. to place a service agent in the field to investigate the placing of cars by the Pennsylvania. It is claimed that certain sections have not received their share and the operators are insisting that the matter be straightened out at once.

NEW YORK

Lower temperatures did not result in any improvement here. Buyers held off and no reasonable offer could induce them to increase supplies. Quotations as a result of the easiness of coal, indicated a downward tendency.

In this harbor on Oct. 20 there were 1,619 cars, which was a slight decrease from the number on hand earlier in the week. In addition there was considerable British coal which was being freely offered at around $7, although it was reported that some had been offered at lower figures.

Exporters of foreign fuel who brought cargoes here without orders for it are finding it difficult to dispose of their holdings. During the week ended Oct. 20 there were reported as arriving in New York harbor six vessels carrying 37,757 tons of coal and one vessel carrying 3,305 tons of coke.

Just now consumers are getting all the coal they need and are not carrying as large stocks as usual. They evidently feel they will have no trouble in getting whatever coal they will need readily and are not worrying about the future.

Southern coal receipts here are smaller. Quotations run about $7 f.o.b. Hampton Roads or $8 this harbor.

B. R. & P. mine run coals are quoted $3.25@$3.50, and slack around $3.50. Other quotations include low sulphur gas coals, $5@$5.50; and high-volatile slack, $3@$3.50.

UPPER POTOMAC

From a labor standpoint, conditions are now almost normal in the Upper Potomac and are gradually improving in the Georges Creek field. During the third week of October, the demand was on a somewhat larger scale than had been the case during the preceding week and that had the effect of hardening prices somewhat.

FAIRMONT

Signs were not lacking at the outset of the third week of October to indicate that the demand was a little stronger, with railroads seeking larger tonnages. The mines in the northern part of the state as a whole, are still seriously handicapped by a car shortage. Western coal was still being moved by way of Charleston.

South

BIRMINGHAM

There has been no change in general trade conditions. Demand for steam coal is only moderately good, such activity as exists being due to some extent to the restricted supply. Although production is being maintained around 345,000 tons per week, shippers are so far behind on contract deliveries, due to the long existing car shortage, that the supply available for spot requirements is not large. The call for domestic is urgent and cannot be supplied under present operating and transportation conditions.

Quotations have shown no material change, minimum prices ranging 25c.@50c. under the maximum schedule on steam grades, with lump bringing the peak figure allowed. For some weeks past domestic grades of the better quality sold to interstate trade have been bringing from $5 to as high as $7. However, Alabama operators have agreed with the federal fuel distributor that they will hereafter adhere to the state schedule of prices for all shipments, which range $3.45@$6.

Car supply for the past week has been about 50 per cent. Slight improvement is expected account of repaired equipment which is gradually being restored to service, but the situation will not be relieved to any great extent without the addition of new cars and a return of the equipment now in use on foreign lines.

VIRGINIA

The field has been unable to maintain its production, largely because of losses sustained on the N. & W. and the N. & N. On other roads mines have increased their output somewhat. There is a little stronger demand in Eastern markets.

Anthracite

Congestion of Steam Loads Now a Disturbing Factor

Production of Larger Sizes Threatened —Brisker Domestic Demand with Colder Weather, Retailers Hard Put to Maintain Yard Stocks—Independents Forced to Distant Markets to Secure High Prices.

Inability to dispose of steam sizes is a disturbing factor which threatens to affect the production of the larger coals. Some companies are running these to storage and various railroad embargoes have been placed against their movement.

The colder weather has brought about a more urgent demand for domestic coal and retailers are barely able to maintain their yard stocks. Independent coals must seek Western and other more distant markets to obtain figures much above the so-called maximum price, as the East will not absorb much tonnage at exorbitant figures.

NEW YORK

The question of how to keep down the accumulation of steam sizes continues to hold the attention of the trade. The terminals are filled and there is estimated to be nearly 100 loaded boats lying in the harbor. Some of the companies are dumping the small coals at the regular storage yards. Embargoes have also been placed on shipments to some of the local piers.

Retail dealers have been getting sufficient tonnage to keep them busy and nearly all consumers have had at least part of their supply delivered. So far as New York goes, it is believed that there will be no extreme shortage and that everybody will be able to get coal.

Independents are not finding it so easy to unload their product on local retail dealers as they did a few weeks back. Along the line and in the West the problem may not be so difficult.

Pea coal is easier and some dealers who have been willing to take fair-sized tonnages in order to get the larger coals have accumulated quite a supply. Stocks of buckwheat are not as large as rice and barley. There were some offerings of washery steam sizes here during the week on a mine basis of $2.25 for buckwheat, $1.90 for rice and 90c. for barley.

PHILADELPHIA

The pinch of fuel shortage is being much felt at this time, following the arrival of actual fall weather. The yards have less coal than at any time since the first shipments came in after the strike. Some of the larger shippers are no doubt spreading their production around, with territory at a distance now getting their turn. If coal had been kept moving here at the same rate it started there would have been sufficient at least to meet present weather conditions.

Mine prices seem now to be fairly well fixed, the companies continuing at their former figures, and with most of the large independents at $9.25. There are, however, reports that quotations on family sizes up to $12 are yet being made, but the general attitude of the retailer is to go without coal rather than pay extreme prices.

There is also some annoyance in the car supply, and while it is not believed that any time has been lost the number of box cars delivered for loading is growing.

Steam sizes have not improved, but it is hoped with better weather conditions that the surplus will soon be absorbed. There is still buckwheat offering at $3.50, but the bulk of the excess tonnage is now selling nearer to $3.75. Barley continues troublesome. Should the shortage of family sizes continue much longer it is quite likely that a fair quantity of buckwheat will be taken in by the retailers, who up to this time have looked with anything but favor on this size.

BALTIMORE

Appeals for consumers to take bituminous as a substitute are falling on deaf ears for the main part. Some of the imported English coal has gone into cellars of homes, but there seems to be a general refusal to take much of the American product. The Maryland Fuel Distribution Committee is pointing out to householders that they should use soft coal when they cannot get anthracite.

The hard coal dealers are up to their necks in work. While some coal is being received it is nothing like enough for urgent demands. Receipts are quickly absorbed and still dealers are harried on every side by insistent customers.

BOSTON

Low temperatures have caused increasing anxiety over the supply of prepared sizes. In view of the relatively short time since mining was resumed the shippers as a whole have done amazingly well. Conditions have been favorable, both water and rail, for heavy movement and thus far New England has fared well.

Dealers are confining themselves to small deliveries in the effort to make their slender stocks go as far as possible. In most cities prices have not been advanced over spring figures.

BUFFALO

All distributors and retailers are complaining of no coal and the weather is all that seems to be in the interest of the consumer. The fixing of a price for independent anthracite seems to have antagonized that interest entirely. All shippers claim to be living up to the price, but there is report of more or less claiming to be out of coal when orders are given. Then the shipper will say he can get coal for three or four dollars more.

The movement by water has increased considerably, but is not up to normal yet. Shipments last week were 117,600 net tons, of which 53,300 tons cleared for Duluth and Superior, 40,800 tons for Chicago and 23,700 tons for Milwaukee. Freight rates remain at 40c. to Duluth, 50c. to Milwaukee and 50 @55c. to Chicago.

ANTHRACITE FIELDS

Things are still peaceful in the anthracite region. Production seems to be on the increase. There is, however, much difficulty in marketing the steam sizes and some of the companies are storing these grades.

The car shortage is not affecting the region as much as it has been in the past and it seems as if this difficulty will soon be done away with.

West

KANSAS CITY

It is difficult to understand the coal situation. Demand is strong for all grades and there is recession in prices for some domestic nut coal. The price for nut has held firm at $6 until recently when it was reduced to $5.50 and mine run from $5 to $3.50@$4. This occurred right at the beginning of winter demand. Deliveries are slow on account of transportation and some of the retail yards are bare of any kind of coal with tonnage in transit that has been out of the mines for over 30 days.

A great many steam plants that put in oil burning equipment are changing back to coal and a great many residences who have burned nothing but coal heretofore are changing over to oil burning because prices for domestic grades are high and the steam grades are low.

Prices are as follows: Kansas lump, $6; Kansas nut, $5.50; Kansas mine run, $3.50@$4; Kansas slack, $2.50

DENVER

A price war in Weld County between two small coal companies has reduced lignite coal in northern Colorado 90c @$1.50 per ton. Some operators declare that coal is selling at $2.25@$3.

Mild weather has broken the cold spell which struck Denver and the state for three or four days. The car shortage is still a serious problem, even though the city and surrounding communities have not been suffering on account of a lack of coal, being on the main lines of transportation and using system cars which are never routed out of the state.

SALT LAKE CITY

The coal business is quiet. Operators have nearly caught up on their orders and will soon be looking for business unless the weather turns cold. The Grand Jury, called to investigate coal prices, is still in session and there is no indication yet as to whether they will bring in any indictments. No one in the business thinks they will. The public is indifferent.

The steel companies are getting ready for business and many believe Utah is in for a big industrial era. Crops have been good this year with fair prices and transportation facilities, on the whole

Chicago and Midwest

Steam Market Continues To Soften Perceptibly

Domestic Demand Swells Day by Day and Car Supply Is No Better So Screenings Remain a Drug—Railroads at St. Louis Confuse Service

Desperate efforts to inject some semblance of life into the steam coal trade are futile. With the slight stiffening of an already firm domestic market, the buyers of steam sizes were more obdurate than ever last week in their belief that screenings must drop lower before anybody will buy them cheerfully—so they obliged in some quarters and dropped. Carterville screenings in the St. Louis market got down to $2.50 and Standard to as low as $1.25. In Chicago a $3-bottom under southern Illinois screenings was decidedly shaky while Standard slid under $2 and central Illinois approached that figure. There remains as strong a feeling that domestic prices are due for a fall in spite of all the coal man's logic that restricted allotments worry nobody. Small deals suit everybody.

Railroad service is not noticeably better. In Indiana and southern Illinois two days' working time a week continues the order of the day with certain localities sometimes attaining the dizzy height of half-time. Thus operating costs per ton are kept high. Rail service for loads is fairly good in most parts of this region—even up into the Northwest which is getting a fair volume of Illinois and Indiana coal—but at St. Louis there is something verging upon a breakdown by the Missouri Pacific and Frisco lines in their terminal handling of coal equipment.

CHICAGO

Snappy weather made the domestic business a little more earnest early in the week and even awakened some other trade sufficiently to bring in a better inquiry for steam but the succeeding warmth took all the crispness out of the whole situation. Retailers are taking all the large sizes they can readily get and are placing their supplies in small lots—which is enough to satisfy everybody since there is still a general belief that coal will be down by the first of the year—and steam buyers look on indifferently, placing no more of the screenings than are offered, but doing it with such nonchalance that the market level from several fields continues to soften.

Standard district coal, always at the bottom, is selling down to $1.75 or even a little lower on occasion, central Illinois stands around $2 and the prime coal of the southern counties has a hard time maintaining its $3 minimum. Some of it gets into distress almost every day and is unloaded at a shade under that in small lots. Naturally lump holds up well but there is no rushing up of the price.

Car supply is little if any better so it is argued that a spell of real cold is going to take so much coal for heating plants that big steam users will have to bid up to get any screenings at all. The buyers, however, calmly await such a period, holding that heavier shipments of domestic will force production of more screenings at a price certainly no higher.

Practically no smokeless is reaching this market now. A thin stream of anthracite is coming in, but no vast stores of such coals are expected. The hard coal retail price is mounting.

WESTERN KENTUCKY

Prices are lower on steam coals, due to slow buying and lack of stocking orders from industries, along with the fact that national production is increasing, and competition for business is beginning to be felt. Freight rates prevent movement at the present time to districts which were large buyers during the period of shortage. Mine run has worked off steadily until it is now quoted $2.25@$2.65, and some for less. Nut and slack is $2@$2.25, and lump, $4.75@$5.25, but with any large demand it would probably advance.

Better river stages are permitting larger movement of coal by water to the lower river markets. Most of the business of the western Kentucky field is now south of the Ohio River, moving to Louisville, Nashville, Memphis and the rural districts. Car supply continues short and is the principal factor in maintaining prices.

SOUTHERN ILLINOIS

As the demand for lump and egg increases there seems to be a falling off in the movement of steam sizes. This has become so pronounced that several mines in the Carterville field have had trouble moving steam coal and have cut the price from $5.50 to $4.25 to steam plants in isolated cases, while screenings are down to $2.50 in some instances. Working time averages two days a week, with some mines getting a trifle better.

Somewhat similar conditions prevail in the Duquoin field, except that egg is a little more plentiful. In the Mt. Olive territory the mines are getting about three days a week, but most of the equipment furnished is the hopper-bottom variety that many retailers cannot unload and this has forced the steam market, especially from egg size down, so that at all mines there is a surplus. This has caused some idleness because the railroads will not furnish empties while there are no-bills on track.

In the Standard district from egg size down there is a surplus, and a scarcity of lump. Mines in this district get from two to three days a week, but are handicapped on account of hopper bottom equipment.

Railroad tonnages from all three fields have been fairly good, but the railroads are not storing any reserve coal. Many mines in this territory have been forced into suspension on account of no-bill screenings and the condition of the steam market is still poor.

LOUISVILLE

Eastern Kentucky, with a car supply steadily at below 20 per cent, is not having much trouble in disposing of production, with the result that prices are fairly firm. The Lake movement along with demand for gas coal, and movement to utility and byproduct plants, is accounting for the bulk of production. Screenings are maintaining values at around mine run prices, due to comparatively small production on account of general lack of lump orders.

It is admitted that with the Lake season nearing a close it will not be long before a larger tonnage will have to be disposed of through other channels, which will have a tendency to break down prices, and force operators to make more lump coal and offer it at lower prices.

Prices are somewhat weaker than they were, especially in western Kentucky. That section is quoting lump, $4.75@$5.25, nut, $4.25@$4.50, screenings, $2@$2.25 and mine run, $2.25@$2.65. Eastern Kentucky is quoting prepared at $6.25@$6.75, mine run, gas, $4@$4.50, non-gas, $3.50@$4.25 and screenings, $4@$4.25.

ST. LOUIS

A little seasonable weather has caused a fairly good domestic demand, principally for Mt. Olive. Very little Carterville is coming in, but Standard movement is better on account of the scarcity of Mt. Olive and Springfield district contributes some. Very little anthracite, no smokeless and no Arkansas has been received and there is a minimum tonnage of coke available. Domestic orders are for small quantities, indicating a continuous call for coal throughout the winter season. Domestic country shows some improvement, but it is scattered and is not in the volume that was anticipated some time ago. Country newspapers are expecting a decrease in the price of coal, which is delaying buying generally.

Locally steam is not good. Steam users are not storing much and the market has practically gone to pieces. Country steam is in somewhat the same condition. Steam buyers figure that with colder weather and an increased production of domestic sizes that steam must necessarily come down to rock bottom and they are waiting until that time. Railroads are reported as having only a day-to-day tonnage available.

The Terminal conditions are unusually bad. At one time in the past week the Frisco had 750 cars it could not receive from connecting lines. The I.C.C. ordered more than half of the Missouri Pacific local switch engines to the repair shops and that road had to borrow motive power from the Terminal. The Frisco is now in the same position and in a general way the local roads are in bad shape. Doubtful embargoes are in effect even on coal.

Eastern Inland

Industrial Demand Gaining; Output Matching Demand

Market Still Weak—Prices Steady Save on Domestic, Which Feels Cold Weather Stimulus—Fixing of Retailer's Margin in Ohio Complicates Situation.

Industrial demand is increasing slightly. The market is still weak, but production is becoming more evenly balanced with current demands. Prices are not quotably higher except on domestic sizes, which are feeling the effects of cold-weather demand.

Price fixing by Ohio on coal mined in that state is causing considerable tonnage to be shipped to outside markets. The retail situation also is confused by the state ruling which regulates the dealer's margin.

Lakes and railroads are taking much of the current production and little free coal is available. This is gradually strengthening the market as the shortage is apparent with the slightest upturn in demand.

PITTSBURGH

There is no material change in the rate of production. Supplies appear sufficient to meet regular requirements of the line trade together with the Lake trade. Car shortages are practically universal, circumstances as a whole indicating that there would be a surplus of coal if the railroads were able to supply all the cars ordered.

Consumers are showing no disposition to stock coal and evidently expect lower prices. The great bulk of current requirements are being met by a regular movement between mines and regular customers, subject in many cases to weekly or monthly price adjustment according to the state of the market, rather than by outright sales and purchases. This condition leaves little demand for the open market.

The market is not closely quotable, on account of there being quite a price range, according to quality. Ordinary steam coal is generally at $3@$3.25, with occasional transactions at $3.50. A fair grade of byproduct can be picked up usually at $3.50, while good gas runs up to $4 for mine run, with 50c. extra for screened. Domestic 1¼-in. lump is $4.75@$5.25, according to grade.

CLEVELAND

The market has begun to stiffen. Prices are higher than 10 days ago. Cooler weather and increasing car congestion have combined to bring about a firmer market. Some of the large coal carriers, which were furnishing a supply ranging from 70 to 100 per cent have dropped to a level of 35 to 50 per cent in the last few days. In view of these things a fuel shortage seems almost inevitable in this district. This is the view of Frank H. Baer, traffic commissioner of the Cleveland Chamber of Commerce, who is serving in the state fuel administrator's office.

In addition to firmer prices, evidence of the turn in the market is found in the fact that many large dealers and operators report they have more orders on their books than they can deliver in three weeks. Because of the low price of $3.56 a ton, fixed by the state fuel commission, for No. 8 mine run, much of this fuel is moving out of the state.

There has been a distinct quickening in household demand. The colder weather has caused this. Pocahontas is still scarce and hard coal is coming into the city in driblets. Under the new state regulations retail coal prices will fluctuate daily. In the past dealers have averaged their costs so they could quote prices for future delivery. They must now base their prices upon the cost at the mine on the day of shipment from which the particular order is filled.

COLUMBUS

With colder weather at hand domestic demand is increasing. Producers and jobbers have many inquiries but since Ohio prices are regulated dealers have to be content with buying West Virginia and Kentucky grades as well as Ohio-produced mine run. Practically no Hocking or Pomeroy lump is going to Ohio dealers, producers preferring to sell outside of the state at higher prices. Retail prices as fixed by the administrator allow a margin of $2.20 over the cost at the mines and freight.

There is a slightly improved demand for steam grades with buying only for immediate needs. None of the larger consumers is showing a tendency to stock up under present conditions, although a few manufacturers are coming into the market. Lake trade is still active although car shortage and congestion is reducing the tonnage.

The car supply is growing less and this is reducing the output in all Ohio fields. The supply of cars in the Hocking Valley last week was about 40 per cent and in Crooksville and Cambridge somewhat less.

EASTERN OHIO

While the field is showing some improvement in output yet because of the continued inadequacy of transportation facilities some apprehension has been expressed by members of the Ohio fuel administration that a famine is in prospect. During the week ended Oct. 14 this district produced 313,000 tons or 50.5 per cent of potential capacity.

With approximately 30 per cent of current output being drawn for railroad fuel and some 60 per cent of the remainder going to the lower ports for trans-shipment to the Northwest, it may readily be seen that at the restricted rate of operations the volume of "free" coal finding its way into the open market cannot be of any considerable magnitude. Steam users are daily becoming more concerned and domestic consumers are beginning to feel more apprehensive. Thus a more insistent demand has developed. Difficulty is being experienced in satisfying the demand. With the exception of slack, which is soft and in abundance because of heavy shipping of ¾-in. to the Lake, other grades are scarce in the open market. Other spot prices conform to maximum figures set by the state authorities. Coal from West Virginia Panhandle is quoted in the open market at approximately the same f.o.b. mine prices. Very little West Virginia or eastern Kentucky coal is arriving as yet because of the transportation situation. It is reported that slack and nut and slack from these mines range $5@$5.50, mine run, $5.50@$6, lump sizes, $6 and up.

Receipts of bituminous coal at Cleveland during the week ended Oct. 14 were 1,471 cars, 360 cars under the preceding week. Of this total 1,210 cars were for industries and 261 for retail yards.

DETROIT

Bituminous coal is coming into Detroit in fair amount, though the average daily receipts fall short of the quantity which dealers estimate as necessary to meet the requirements. Industrial plants seem to be releasing orders only when compelled to replenish their supply for current needs.

Retail dealers, also, are inclined to proceed cautiously in the matter of building up yard stocks. The waiting attitude of their customers impresses jobbers and wholesalers as an indication of the expectation that coal will be obtained at lower prices after a while.

Hocking lump and egg is quoted at $5.50@$6, mine run, $3.75@$4, nut, pea and slack, $3.25@$3.50. Fairmont 2-in. is $5, mine run, $4.50@$4.75, slack, $4.50. Pittsburgh No. 8 2-in. is $5, mine run, $4.25@$4.50, slack, $3@$3.75. West Virginia and Kentucky lump and egg is $6.25@$6.50, mine run and slack, $4.50@$4.75. Smokeless lump and egg is held at about $8.50, mine run $6.50@$6.75.

BUFFALO

Some shippers report the market stronger, but it is hard to find any advanced prices. The consumers are buying as they please. No sort of warning of coming storms or still scarcer car supply can scare them.

The price was seldom as varied as it is now. Mine owners complain as much as ever of car shortage, but in fact that is all that is saving them from a total collapse of the market.

The weather has done what it could to check the market. The jobbers know this and confess that it has so far done much toward spoiling their arguments. Quotations are: $5 for Youghiogheny gas; $4.50@$4.75 for Pittsburgh and No. 8 2-in. steam; $4@$4.25 for Allegheny Valley and other mine run; $3.25 for slack.

NORTHERN PANHANDLE

Mines are much handicapped by their inability to ship as large a tonnage to Western markets as the market would permit, owing to congestion on roads. It has been found particularly difficult to get coal through to the Lakes. There is a more pronounced demand for mine run and prices are advancing a trifle.

Northwest

First Cold Worries Few Folks Around the Lakes

Considerable Flow of Cargo Coal Both Hard and Soft Allays Worst Fears but Fuel Is Doled Out Carefully—Steam Prices Soften.

The Northwest finds little cause for worry in spite of the inevitable domestic rush that was started by the first cold snap. Prices on domestic are not hiking even though the supply does not equal the demand. Heavy Lake shipments continue and it is probable they will until Dec. 1. Rail coal from Indiana and Illinois is coming in in fair volume. The general result is nobody is contracting and steam prices are headed downward.

Hard-coal cargoes already in have been doled out in small quantities but even that does not cause much concern over the future. It certainly has not set up a demand keen enough to take out of dealers' yards some low-grade soft coal bought at fairly high prices last summer. Both dealers and dock men have had so much experience buying high-priced coal for protection only to have it left on their hands at the end of the season that they are not stocking heavily now.

MINNEAPOLIS

A flurry of "square winter" with snow started a rush of retail business in the coal offices, but, with the passing of the storm, came an end to the rush. The hard coal situation has not changed particularly in some weeks. The fuel commissioners have pledged that a certain tonnage will be supplied the Northwest. Minneapolis is to get 122,931 tons against 203,581 tons last year. St. Paul is to have 85,476 tons against 142,450 tons last year. This may be decreased by transportation difficulties although it is hoped to move it by Lake and rail or all-rail. It now appears unlikely the Northwest will get over 70 per cent of the normal anthracite tonnage.

The soft coal situation is settling to some extent. There is now enough for any present and early future need, and buyers are not at all worried. The winter's requirements for the docks is being scrutinized carefully by dock men. They say that there is a good tonnage of all-rail coal coming into these cities despite the car shortage, and are going cautiously in building up their stocks. Already they are having difficulty in getting the price they must ask, and they anticipate the possibility of a larger tonnage having a still further depressing effect.

So October is showing a decline in tonnage moving to the docks, as compared with September. Some of this is due to transportation difficulties and some of it to dock operators holding off from buying. There is likely to be an increased all-rail tonnage later on so that the dock store of perhaps 4,000,000 tons, plus what comes from the all-rail fields, should serve to carry the Northwest through the winter.

MILWAUKEE

Frosts and some snow have increased the anxiety throughout Wisconsin regarding the winter supply. Dealers report an increasing domestic demand. Steam is slow, however. The State Fuel Commission announces that West Virginia smokeless producers have set a maximum of $6 at the mine for prepared sizes, and Pennsylvania anthracite has been fixed at $8.50. With these figures as a basis, the commission expects to be able to check profiteering. Prices on both hard and soft coal have undergone no change since Oct. 1. No coal at premium prices has appeared in this market yet.

Hard coal must move more freely than at present, however, if this schedule is to be realized. Thus far in October, eleven cargoes of anthracite, aggregating 86,952 tons, and fifty-three cargoes of soft coal, aggregating 473,416 tons have been unloaded at the various yards. The season's receipts by cargo to date now total 87,652 tons of anthracite, and 1,764,371 tons of soft coal. Last year during the same period 815,622 tons of anthracite, and 2,149,410 tons of soft coal were received.

DULUTH

The first snow has fallen and cold weather seems to have definitely set in. Householders are straining every effort to get coal into their bins, and dealers find it impossible to make local deliveries.

During the week forty-two cargoes arrived at the port. Four were of anthracite. Twenty-four are on the way of which four more are hard coal. This, it is considered, will relieve the situation considerably, as the volume reported coming from lower ports indicates that the movement will keep up.

Shipments throughout the territory are excellent. Duluth is in a good way for cars, as grain shipments to the harbor leave many empties to take coal back. Despite this there has been an accumulation since Oct. 1 of about 600,000 tons more on the docks.

A heavy call for Pocahontas has about wiped out the supply. Prices on hard coal remain the same as quoted last week. The market in bituminous coal is weakening at the usual point—screenings. These are quoted at $7 for Youghiogheny and splint against $7.50 last week and Hocking screenings are 50c. below this. Prices for lump and run of pile remain the same but are expected to drop. Railroads are not buying much.

New England

Big Consumers Await Events; Some Smaller Ones Buying

Business Is Light, Close Canvassing Being Necessary to Place Tonnage—Hampton Roads Coals Sluggish—All-Rail Fuels Quoted Lower to Maintain Output.

Only here and there is the current market at all responsive to selling efforts. The larger buyers have accumulated some reserves and have settled down to await developments in November and December. The various trade factors are enjoying only light business in consequence, and what tonnages are placed are the result of close canvassing.

A few relatively small users have concluded that present prices are about as low as they could reasonably expect, and these are now beginning to take on the coal they have been talking about buying since early in July. Hampton Roads coals are sluggish and all-rail fuels are quotably lower in an effort to maintain production.

The $3 level at the mines has been touched. Locomotive coal of fair grade has been offered at that figure per net ton, but no sales have as yet been reported. The present all-rail tariff to New England points is still so high that coal within reach of Tidewater still costs less by the water route. Coastwise freights are now on what is considered practically a minimum basis on present costs, and when the delays in rehandling at Boston, Portland, and Providence are cleared up it is likely that receipts of Hampton Roads coals will measurably increase.

Cargoes of British coal continue to arrive, but in much smaller number. A few of the larger corporations profess to be well satisfied with their purchases, and are quoting quality and reasonable prices of these grades as an argument to force down the price of home coals. Some of the high volatiles that originate on the other side have given fair satisfaction as railroad fuel, and renewed shipments have been offered recently at a range of $6.50@$7 delivered alongside.

Buyers in general seem little disturbed over the threatened car shortage. Strenuous efforts to sell coal the past three months have convinced most consumers that orders will be even more scarce than cars, provided cars are to be short as predicted.

In railroad circles there is more or less discussion of "assigned cars." There are operators who see in this a deliberate attempt to force prices to still lower levels, and without doubt any such more would be resisted under anything like present conditions.

Cincinnati Gateway

Unsettlement Continues, Due to Diverse Causes

Some Steam Coal Sacrificed to Escape Demurrage—Clog in Movement Reported—Outside Competition a Pressing Factor—Price Fixing Boosts Retail Quotations.

Outside competition, shortage of cars and a soft market have been causing a continuation of the unsettled conditions at the Cincinnati gateway. Rejections have grown to the point where some steam coal is being sacrificed where it had begun to pick up demurrage. These cars in distress have sold down to $3, but that is not nearly as ominous as the reports coming in from Russell, Ky., and Portsmouth, Ohio, to the effect that the quick movement is beginning to clog there.

The outside competition, perhaps, has the greatest effect upon this market and reports that byproduct and gas coals from the Pittsburgh belt were being offered 50c.@75c. cheaper than the Kentucky and West Virginia products caused anxiety. On the other hand, reports from companies handling high-grade coals show that the slump has not amounted to more than 25c. a ton on the week.

LOW VOLATILE FIELDS

New River and The Gulf

New River producers were unable to take advantage of the better Western market for prepared owing to an embargo on the C. & O., which for a few days diverted more coal to Eastern markets and to Tidewater, where the demand has been none too strong.

Gulf producers also had to ship all their product to Eastern markets, where there was a little better demand, although a surplus was reported at Tidewater. Little tonnage was available for spot sales, due to the large number of contract orders to be filled in the face of the car shortage. Prepared grades were still high, with no prospect of an increase in the supply.

Pocahontas and Tug River

Pocahontas production is still being seriously curtailed by the inability to secure an adequate supply of cars, losses amounting to nearly 400,000 tons per week. The output is not much more than sufficient to take care of regular customers. Little smokeless has been reaching markets in the West but notwithstanding the scarcity of smokeless, prices as a rule have been about on a Hoover level.

Tug River mines are slowly recovering from a slump in production brought about by numerous embargoes and a general shortage of cars. Even making allowance for an improvement in transportation conditions, the supply is still short of the demand, so much so in fact, that producers have not been quoting prices.

CINCINNATI

The smokeless situation continues much as it has been. The Pocahontas producers, however, have finally been able to get smaller equipment to their mines, which will result in a heavier tonnage being shipped to the West. Some producers say that they have about caught up with their contract orders.

The situation of the steam coals is the weakest on the list. Customers who were taking anything that looked like coal are now discriminating and demanding quality. Lake buying has been a little better with the end of the season in sight and the automobile and steel people seem to have no limit to their capacity for good coal.

The retail situation has been muddled by a ruling from the Ohio authorities fixing the price of Pocahontas at $11.34. Dealers were selling this lump at $10.50@$11 and mine run at $9.50. Splint lump is ordered sold at $10.39@$10.49, whereas the dealers had been selling it at $8.75@$9.60, and the slack, $7.25@$8.50.

HIGH-VOLATILE FIELDS

Kanawha

Claims of C. & O. officials that they were able to furnish open-tops to the extent of 60 per cent of normal were not being borne out by loadings during the third week of October. Mines were not securing more than a 30 per cent supply. The Western market was closed to shippers for several days by an embargo on all coal destined for points west of Handley and there was nothing to do but let coal accumulate. The embargo may have had the effect of hardening Western prices. At any rate, mine run increased 50c. a ton and stopped the downward tendency.

Northeastern Kentucky

Claims of railroad officials that the car supply is about normal and the expression of public officials that prices are too high are disputed and resented by mine owners. Under present conditions it is impossible to produce anything like the tonnage for which there is a market, and hence production costs are high.

Logan and Thacker

Scarcity of equipment continued to handicap Logan mines. The Western market has shown signs of greater activity. With the Western movement stopped for a few days, the Lake movement ceased also. There was more general inquiry for steam coal, however, than there has been, indicating that supplies are running short in some quarters.

Thacker production was only 90,000 tons as against car shortage losses of 150,000 tons, so that Western shipments were materially curtailed. Producers are hardly able to take care of the requirements of their regular customers, much less sell coal on the spot market.

Coke

CONNELLSVILLE

The break in coke prices which began nearly a fortnight ago brings lower prices almost daily, and finds only an occasional purchaser. The market has been under the double pressure of increasing production and of consumers holding off. There is room for at least $2 further decline in coke without the price going below the market price of the coal involved plus the cost of coking, while sometimes coke has sold at less than the price indicated by the usual formula. Coal, furthermore, may decline, and thus furnacemen have good reason for deferring purchases as much as possible.

To a large extent car supply has been the limiting factor in production. At the same time many of the strikers have been quite reluctant to go back to work. At certain plants officials of locals have instructed strikers to return to work while at other plants attempting to resume no such instructions have been given, indicating that the U.M.W. has not formally called off the strike and would be content to see the men stay out as long as they will.

The market is quoted at $8 for furnace coke, this being an asked rather than a bid price, and $10.50@$12.50 for foundry.

The *Courier* reports production during the week ended Oct. 14 at 98,700 tons by the furnace ovens and 42,010 tons by the merchant ovens, a total of 140,710 tons, in increase of 14,360 tons.

UNIONTOWN

Furnace coke this week struck a downward stride, joining coal in the low price movement. A number of factors contributed to the lowering of the coke prices, principal of which is a substantially increased production, which temporarily at least is more than the market can readily absorb. Coupled with that feature is the delivery of British coke upon a basis of approximately $8, Connellsville. It is reported that some consumers who placed orders for foreign coke while the Connellsville market was at the $13 level are now seeking cancellation in order to substitute domestic fuel.

Coal for some time has been described as soft, due to a great extent to resumption of operations at union mines, but the coke market since production was resumed to the extent of establishing one has been strong with an increasingly active demand. That sufficient surplus is now being produced to bear down the market is taken as proof that the union has lost its effectiveness in curtailing production.

BUFFALO

The trade is dull, with some report of price reduction. Jobbers quote 72-hr foundry at $13@$13.50, 48-hr. furnace at $11.50@$12 and domestic at $11, with $3.25 added for freight.

News Items From Field and Trade

ALABAMA

The following statement relative to the [illegible] of prices on domestic coals produced in Alabama and adopted to govern [illegible] has been issued by the [illegible] Administrator, following a conference of coal operators held in Birmingham. "The prices fixed by the code on domestic coal are as follows: Big seam group, $3.45; Four-foot group, [illegible]; Cahaba block coal group, [illegible]; Montevallo lump group, [illegible]. These prices are maximum [illegible] below which no coal originally within the code has been shipped on coal moved across the state line. The operators representing approximately 65 per cent of the entire production, signified their willingness to sign [illegible] contracts at [illegible] effective at once, the above schedule of prices on interstate domestic [illegible]."

COLORADO

The following interesting figures from the [illegible] annual report of the **State Inspector of Coal Mines** of Colorado cover operations in 1921: Number of mines operated, 249. [illegible] and old mines opened, 11 mines closed, 4 abandoned; [illegible] of 249 mines [illegible] to [illegible] production.

TONNAGE PRODUCTION IN 1921

	Net Tons
[illegible]	1,454,264
[illegible]	791,345
[illegible]	4,844,472
Anthracite	63,764
Total	8,141,845
[illegible]	4,845,446
[illegible]	4,247,581

COKE OUTPUT COLORADO 1921

Coke produced	651,179
Coke sold	589,267

COLORADO PRODUCTION STATISTICS

Miners employed, [illegible]	4,769
Machine	3,346
Total	8,129
[illegible]	[illegible]
Tonnage	14,164
Average number of [illegible] worked	164.4
Daily production per man	6.8
Annual production per man	1,124.3

ILLINOIS

The mine of the **J. R. McCoy Coal Co.**, [illegible], has been sold to two men of Herrin, **J. C. Lewis** and **R. W. Hawkins**. The new owners will operate the mine under the name of **Lewis & Hawkins**.

The **Cahvin Coal Co.**, with headquarters in Marion, has negotiated with the **Southern Illinois Coal Co.** for the purchase of the mine known locally as the Burkhardt at Herrin, some of the mule barn [illegible]. The company is incorporated for $40,000 and is planning to add [illegible] to the mine preparatory to its reopening.

A. S. Austin, of Milwaukee, of the **Kanawha Fuel Co.**, who for the [illegible] has been in charge of the **Old Ben Mining Co.**, which is controlled by the Kanawha company, has resigned. The mine was idle for over two years.

Fred Harbin has passed the coal mining [illegible] to the farm of Rudolph Wiehl, three miles west of Belle and [illegible] Illinois and [illegible] for immediate operation.

With the [illegible] of a new coal [illegible] on the property of **M. Wolf**, [illegible] east of Wamac, [illegible] will be a short [illegible] and will be [illegible] that the coal and [illegible] will be run to the [illegible]. Two veins [illegible] have been [illegible]. Which one of the two [illegible] the farm where a 6-ft. vein of coal was found [illegible] on the Wolf farm [illegible].

[illegible] in the [illegible] of Orient Tower by the **Central Illinois Public Service Co.** The plant will require about one year for construction and will furnish power to over thirty southern Illinois towns and many towns in Missouri and Kentucky, as well as supply the needs of a large number of coal mines in Illinois. The plant when completed, will be as large or any similar plant in the world.

Reports from all Southern Illinois coal fields show an **alarming water shortage. At** many mines arrangements have been made with railroads to supply water in tank cars. At Pana the city has decided to shut off the supply to the mines as a safety move in case of fire.

Milo Smith Ketchum has been appointed as dean of the College of Engineering and director of the Engineering Experiment Station, University of Illinois. He is a member of the American Society of Civil Engineers, the American Railway Engineering Association, the American Society for Testing Materials, the Colorado Scientific Society, the Society for the Promotion of Engineering Education, American Association of University Professors and a fellow of the American Association for the Advancement of Science. He has carried on a consulting practice for 20 years, making a specialty in steel and reinforced concrete bridges, mill and mine structures, and has had considerable experience in valuation work and in giving expert testimony.

INDIANA

The Indianapolis Fuel Committee, appointed by Mayor Shank to co-operate with the federal and state authorities in attempting to regulate the distribution and price of coal, has been revised in its membership with the appointment of John A. George, president of the Indianapolis Coal Co., and Michael Shea, a former councilman, as members of the committee. Both men accepted the appointment. The mayor said he intended naming a legal adviser to work with the committee and has asked that the committee meet soon.

The Spencer Coal and Mining Co. has been organized at Bedford, for the purpose of doing a general mining business. The company has a capital stock of $10,000, which will be increased later. The directors are Simon H. Crabtree, Edna Crabtree, Henry Spencer and Emma B. Spencer.

Many operators in the "pocket" counties of Indiana along the Southern are preparing to file suits against the railroad in case the investigation, now being conducted, reveals that the railroad company is favoring some mines and allowing others to remain practically idle, according to J. Woolley, of the **Woolley Coal Co.** Statistics now are being compiled by the Southern Indiana Coal Bureau, which will indicate the conditions of the neighborhood mines, according to Mr. Woolley.

The Imperial Coal Co. recently was organized at Terre Haute, with a capital stock of $150,000. The organizers are W. S. McCord, M. R. McCloud and Louis Clements.

IOWA

Pocahontas County farmers will burn their corn for fuel, it was decided at a large [illegible] meeting held at Laurena recently. The action was taken as elevators in this part of the state cannot handle grain because of the car shortage. Also, it was pointed out the action would save two freight hauls. Eighty per cent of the farmers in this county cannot pay their taxes, [illegible] and interest on farm mortgages in many cases is overdue. The only relief the farmers see is to unite in a state-wide movement to burn corn unless a reasonable profit over cost of production can be obtained.

KENTUCKY

A [illegible] is in preparation for the meeting of the **Kentucky Mining Institute** at Louisville, Nov. 3 and 4. J. M. Dewberry, of the L. & N., is scheduled for a talk on traffic conditions which should prove of especial interest.

The Southern Railroad, which recently settled its strike of shopmen, is improving service in the mines in southeastern Kentucky which it serves. These mines for weeks were completely tied up.

The Miners' Syndicate of America, Pikeville, Pike County, with a capital of $15,000, has been chartered by W. D. Sanders, F. M. Woods and M. M. Martin, all of Pike County.

The Detroit Edison Co. has sued the Monty Eastern Coal Co. of Pineville, in the United States District Court in Cincinnati for $18,000 upon the grounds that they had failed to live up to a contract made through Eaton Rhodes & Co. as agents for the Kentucky company. It was charged that the Monty Bottom company was to ship its entire production to the Detroit concern.

On recommendation of Lawson Blankenship, chief mine inspector, of Kentucky, Gov. E. P. Morrow has appointed **M. S. Blythe**, of Whitley, to succeed **W. H. Hunt**, as assistant state mine inspector for the second district, stationed at Central City.

The Kentucky Gas Coal Co., jobbers, recently incorporated, has located at 321 Starks Bldg., Louisville, and will handle gas, steam and domestic coals, including Kentucky, Indiana, West Virginia or Tennessee fuels. L. P. Young, formerly with the Harlan Coal Co. is president, and L. D. Young, formerly with the Wallins Creek Coal Co., is secretary-treasurer.

MASSACHUSETTS

The Fairmount-Worcester Coal Co., of Worcester, has recently been incorporated under the laws of the state to carry on a coal supply business, etc. The firm has been organized with a capital stock of $50,000, and the officers chosen are: Raymond Tracy, of Millbury, president and treasurer, and Irving W. Mullett, Worcester, vice-president.

The Progressive Coal Co., Inc., Cambridge, has incorporated the business under the laws of the state. The capital stock is $50,000, and the officers chosen are: Morris Rudnick, president; Joseph F. Rudnick, vice-president, and Benjamin Rudnick, treasurer.

The Rome Wire Co. recently opened a Boston sales office in the Little Bldg.

MINNESOTA

The federal fuel officer has ordered that coal cars which have been left on track for an unreasonable time are to be seized and unloaded without delay. Cases of cars having remained without unloading for five to twenty days are reported.

The new 10-ton bridge of the **Superior Coal & Dock Co.** has been placed in use. The company's dock is at Duluth-Superior harbor and the new bridge places it on a par with the best as far as handling is concerned.

The Minnesota State Fuel Administration has declined an offer of 160 acres of coal lands at Bowman, N. D. It is assumed that the land which has a vein of lignite said to be 60 ft. thick, contains 12,000,000 tons of fuel which would make the price of the coal in the ground around 1c. a ton.

MISSOURI

The Lincoln Coal & Mining Co. has been organized at Kansas City with a capital stock of $10,000. The company will prospect for coal, oil and other minerals. The shareholders are Howard N. Hanson, John J. Caldwell, A. Scott Myers and Tom C. Hanson.

The property belonging to the **Hanke Coal Co.**, at Huntsville, has been sold at sheriff's sale at the court house in that city to **Norman Johnston** of Huntsville, for $4,000. His was the only bid. It is claimed that the owners spent in the mine and its property the sum of $35,000.

The Tebo Coal Co. has leased a large body of land in the vicinity of Chloe several miles from Lowry City, and will begin operations as soon as a steam shovel can be transported from Pittsburgh, Kan.

The Callaway County Coal Co., which has been operating a steam shovel coal stripping proposition near Carrington, Mo., for the past nine years, is to be dissolved.

One of the chief reasons for the better movement of cars in the St. Louis and Missouri territory is **C. D. Thomas**, in charge of the office at St. Louis recently established by the service department of the I. C. C. Embargoes that tied up loads and empties were investigated and other "kinks" straightened out. The results in the first few weeks were so gratifying that several telegrams were sent to Washington requesting the continuance of the work.

NEW YORK

Maximum prices in New York City for hard coal sold in small quantities to the poor are being put into effect, according to an announcement by **A. S. Learoyd**, district fuel administrator for Greater New York and Long Island. The prices are said to be 10c. per 100 pounds lower than the prevailing prices last year.

Charles S. Allen, in association with Karl Knox Gartner, of the firm of Baker & Baker, has been engaged by the receivers of the **Tidewater Coal Exchange, Inc.**, to present to the Interstate Commerce Commission the matter of refund and remission of demurrage charges amounting to about $990,000 which have been apportioned against members of the Exchange. Mr. Allen will also take up with the debtor and creditor members the matter of settling the outstanding debits and credits.

The Astel Coal Co. has been established in Buffalo, managed by William C. Strassburg, formerly in the coal trade at North Tonawanda, and William E. Schmidt, a former city coal salesman.

NORTH DAKOTA

The Haynes Coal Mining Co., of Haynes, has secured a temporary injunction against the local of the U. M. W., restraining it from interfering with the operation of the mine. The company accepted the Cleveland peace plan, but the local wants $1.50 increase, and continues to picket and guard all approaches to the mine, meet trains and watch all roads. The union is allowed one representative at each established mine entrance to advise would-be employees of the strike and to use peaceful methods to induce them not to work.

North Dakota lignite mines are being opened up wherever the coal seams are readily accessible to railroads and of no great depth. Coal lands are also being bought up for future developments. Production for 1922 will be several times that of a year ago.

OHIO

The Erie Coal & Coke Co., Cleveland, has been incorporated with an authorized capital of $25,000 to mine and sell coal and to do a general jobbing business in coke. Incorporators are H. C. McCoy, H. C. Roberts, J. W. Johnson, E. B. Renenzer and Henry Stern.

Ohio jobbers held a session in Columbus recently in an effort to bring before Fuel Administrator Neal their position in the scheme to regulate prices. Practically all Columbus jobbers attended and those present from out of town were E. W. Astel, Astel Coal Co.; H. S. Fahey, A. & L. Coal Co.; R. S. Bain, Central Coal Mining Co.; P. E. Barrie, Montout & Northwestern Coal Co., and J. L. Deegan, Goff-Kirby Coal Co., all of Cleveland; J. W. Morgan, J. W. Morgan Coal Co., and C. A. Sloane, Jackson Hill Coal Co., Jackson; J. B. Patterman, Blue Ash Coal Co.; Charles R. Moriarity, Cabin Creek Consolidated Coal Co., and J. G. Metcalf, Reliance Coal & Coke Co., all of Cincinnati; Clyde H. Hoyt, C. H. Hoyt Coal Co.; Clint Cole, Cole-Basinger Coal Co., and H. J. Heywood, W. A. Gosline Coal Co., all of Toledo. After a discussion of the position of wholesalers, a committee was named to call on the administrator. Their report was very encouraging as Mr. Neal reported that he was giving the jobbers serious consideration and probably provisions would be made soon for a fair commission on the business they handled. It was believed that the jobbers' position was due more to the lack of cars than to the rulings of the fuel administration.

Coal operators in Ohio are requested by the federal fuel representative to **confine their shipments to short hauls and normal markets.** "There is a tendency, especially on the part of some operators, to ship coal to any point where the highest prices may be obtained," the statement reads. "Shipments to distant destinations delay return of empty cars and impede the car supply. Short hauls, or at least those to normal markets, are of great assistance to the railroads in returning empties.

Representatives of the **New Pocock Coal Co.** and the **Fox & Howells Mining Co.**, both of Massillon, presented facts in regard to their protest against the maximum fair price for coal at the Ohio mines, in a meeting before Fuel Administrator Neal. Each maintained their average cost of production has been $4.93 per ton. On this basis they claim the cost for Stark County of $4.86 is below cost of production and therefore unfair to them.

OKLAHOMA

Nine men are dead as the result of a gas explosion which wrecked mine No. 11 of the **Progressive Coal Co.**, near McCurtain. Rescue squads reached the entombed men shortly after the blast, as the mine is shallow. The wrecked mine was a slope, built through an abandoned strip pit in which coal was found about 500 ft. from the opening. Steps are under way by federal and state officials for a thorough investigation of the cause of the blast.

R. K. Schutt and associates have sunk a shaft on coal leases in Section 2, 18, 27, to a 30-in. vein of coal near Wagoner and are building a sidetrack half a mile to the Iron Mountain Ry., preparatory to mining on a large scale. Besides the shaft mine the company will open a strip pit.

PENNSYLVANIA

At a conference of the directors of the Central Coal Association and the Association of Bituminous Coal Operators of Central Pennsylvania held in Altoona, **Charles O'Neill** of Altoona and **B. M. Clark** of Indiana, president of the latter association, were chosen to represent central Pennsylvania at the joint conference of miners and operators to be held in Chicago on Nov. 14. A special committee composed of **B. M. Clark, R. H. Sommerville, J. Webb Shillingford, S. T. Brown, Rembrandt Peale, C. B. Maxwell,** and **Charles O'Neill** was appointed to consider the manner or method of representing Central Pennsylvania before the fact finding commission recently appointed by President Harding.

The Dauphin County Court last week heard additional coal tax cases and questions of the right of the commonwealth to tax coal companies for their own fuel used in boilers at the mines and for refuse and culm coal used in the preparation of coal briquets were raised. The appeals were those of the **Scranton Coal Co.**, and the **American Briquet Co.'s** Lykens plant. No decisions will be rendered until settlement of the Heisler appeal before the United States Supreme Court. The briquet company's main contention was that it is not a coal producer but a manufacturer.

As a result of the recent **Bethlehem-Lackawanna Steel Company merger**, the Bethlehem Mines Corporation, which is the mining subsidiary of the Bethlehem Steel Co., took over the Lackawanna coal interests. These consist of the Ellsworth Collieries Co., operating in Washington County, and the Lackawanna Coal & Coke Co., operating at Wehrum. T. R. Johns, manager of coal mines, has established his main office at Hellwood, Indiana County, and made the following appointments: George Lindsay, division superintendent, Hellwood division, Hellwood; H. C. Ford and C. E. Kirker, superintendents, Hellwood division, Hellwood; R. E. Abrams, superintendent, Hellwood division, Wehrum; J. F. Fleming, chief engineer, Hellwood division, Hellwood; S. Steinbach has been retained division superintendent, Preston division, Reedsville, W. Va.; M. B. Mitchell, division superintendent, Marion division, Barrackville, W. Va.; C. F. Welty, superintendent, No. 11 Mine, Marion division, Barrackville, W. Va.; H. R. Nuzum, superintendent, No. 42 Mine, Marion division, Dakota, W. Va.; J. P. McCune transferred from division superintendent of Marion division, Barrackville, to division superintendent, Ellsworth division, Ellsworth.

TENNESSEE

It is reported at Chattanooga that settlement is near in the bankruptcy litigation involving the **Dayton Coal & Iron Co.**, of Dayton, which has been in the courts for nine years. The proposed settlement it is reported calls for full payment of all creditors' claims in Tennessee and 85 per cent to outside creditors. Whether outside creditors would stand for such a division when submitted by the federal referee is a question. At present H. S. Matthews is operating the mines for New York interests.

UTAH

The permit granted the **Salina Canyon Coal Co.** to sell bonds has been revoked by the Securities Commission. The license was suspended some time ago and it is reported by the secretary of the commission that "certain information" desired by him was not given. The permit gave permission to sell $500,000 worth of bonds.

A Salt Lake City newspaper comments on the fact that while the average wage paid to school teachers is about $4 or $5 a day, foreigners, who cannot even speak our language and have no regard for our laws, can get $15 a day for digging coal in Carbon County. Since the strike settlement many of the men who went out are pleading for their jobs again. In some cases they say they were "crazy" in others that they were "deceived." There is a surplus of labor everywhere in Utah.

WASHINGTON

About 60 per cent of the coal production of the state was represented at the recent conference in Cleveland. **D. F. Buckingham** of Seattle, general manager of the Roslyn Fuel Co., and **John H. Wallace**, also of Seattle, were the delegates of the operators association, and the union was represented by **W. C. Thompson**, of the U. M. W. The Washington delegates represented virtually none but eastern Washington mines, since nearly all the western Washington mines are now operating on the open-shop plan.

WEST VIRGINIA

The Nuttallburg Mine, in the New River field, owned by Henry Ford, has been closed down and dismantled. Ford has owned the mine for several years, having operated it under a lease since the purchase.

The Fayette & Kanawha Coal Co. has secured a judgment of $50,[illegible] in the circuit court of Kanawha County against the **Lake & Export Coal Corporation** for breach of contract. It was contended by the plaintiff that the defendant company entered into a contract to take over the output of two mines owned by the plaintiff company from June 26 1920, to June 26 1921, that the defendant company handled the output until Dec. 10, 1920, and at that time refused taking the output when the price began to drop. The court allowed the plaintiff damages at the rate of $2 per ton on the estimated output of the two mines from the time the contract was broken until the expiration of the contract.

Judgment was given the **New England Fuel & Transportation Co.** in five out of eleven cases which it had instituted against striking miners for rent, light and rent. One of the judgments was for $4[illegible]. Those against whom judgment was obtained are now working in other fields.

Boyd M. Smith of [illegible] has been named as manager of the newly established Fairmont office of Whitney & Kennedy, a coal brokerage concern of New York and Philadelphia. A year or so ago Mr. Smith was in charge of the Fairmont office of Whitney & Kennedy. Associated with Mr. Smith at Fairmont is Ed H. Pritt.

With a view to engaging in the coal business on a small scale citizens of Mt. Hope have organized the **Greenview Coal Co.**, the headquarters of which will be at Mt. Hope. The company has a capital stock of $[illegible].

The Balwood Coal Co. has been organized with a view to operating on a small scale in the New River field. The company is capitalized at $[illegible]. The principal office will be at Glen Jean. Identified with the concern are William R. Ballard of Glen Jean; Clyde G. Wood, Laura B. Wood of Kilsyth; Blanch Bolton and [illegible], Roberts of Mt. Hope.

WYOMING

The Mark Shields Coal Co. is opening what is claimed to be the third largest coal deposit in the world, five miles east of Gillette, on the C. B. & Q. The seam, according to reports, extends to a depth of [illegible] ft. and covers an area of [illegible] acres.

The organization meeting of the **Albany County Coal Co.** was held at Laramie recently to complete the incorporation of the company and the election of officers. The company will have a capital stock of $[illegible], and will maintain its principal offices at Cheyenne. The officers chosen were as follows: President, J. Alfred Nelson; vice-president, C. P. Scott; secretary-treasurer, V. L. Walker. Directors: J. F. Brigham, C. P. Scott, V. L. Walker, J. Alfred Nelson, W. P. Scott, Otis Osborne and C. L. Craig.

CANADA

With the object of making available for supplying Canada's coal necessity from the mines owned and to be opened by the Canadian Pacific Railway, and with special reference to the situation in Quebec and Ontario, the Canadian Pacific Railway Co. has organized a committee of coal and mining experts under the chairmanship of Dr. Charles Camsell, Deputy Minister of

WASHINGTON, D. C.

J. B. Eby has completed work for the U. S. Geological Survey in the Wasatch Plateau coal field in south central Utah.

W. C. Mendenhall, of the U. S. Geological Survey, has returned to Washington after an extended Western trip.

Traffic News

President W. J. Harahan of the Chesapeake & Ohio, has made the pioneering announcement that the old feud between that railroad and the Baltimore & Ohio is at an end. We have not yet had time to get in touch with reference to securing business [illegible] and are already beginning to make some headway. We have ordered [illegible] Gondola cars, delivery of which will be started next month. We have also bought [illegible] cars and four [illegible] Mikado locomotives. Several [illegible] we had [illegible] We will [illegible] quality, but it will require [illegible] We are quite alive to the situation and hope to be able to [illegible]

The application of the **Kanawha & Michigan Ry.** to extend its connecting track to the Chesapeake division of the B. & O., between Gordon, W. Va. and Elkins, which was to have been heard on Oct. 19, has been postponed for thirty days.

That coal mines in certain districts in the coal region of West Virginia is hampered for cars on each week day that the railroad embargoes it, Charles and other members of the Monongahela Valley at a meeting held at Morgantown. The opinion was expressed during the meeting that although West Virginia was trying to get a [illegible] established on intrastate freight, the [illegible] charged with responsibility in the matter by the last session [illegible] of the **Rockland Coal Mining Co.**, on July 11, will have to stand trial on the charge, whose [illegible] crime is alleged to have been committed.

Rumors have been in circulation for several weeks to the effect that **Henry Ford** has been carrying on negotiations for the purchase of the **Wabash and the Virginian railroads**. For several years there has been more or less discussion as to the extension of the Virginian down the Guyandotte River to Huntington. If Ford should acquire the Virginian, it would be possible to connect that road with the N. & W. by making the necessary connection between Deepwater and Huntington.

One factor concerned with the water coal problem, as it affects transportation, is the [illegible] and a number of railroads have [illegible] the I. C. C. in order to [illegible] the L. & N. to put in [illegible] rate schedules from eastern Kentucky, Tennessee and southwestern Virginia points to [illegible] points in Minnesota, South Dakota and Wisconsin. Railroads which would benefit from the proposed rearrangement of the [illegible] have not yet put forth [illegible] The [illegible] already took [illegible] to Oct. 15.

A shortage in cars for coal mines on the L. & N. at present is [illegible] officials of that road have announced. This statement was accompanied by information showing the large [illegible] of that company. Between 20 and 25 new coal cars are being delivered daily to the L. & N. by the Cambria Steel Co., Carnegie, Pa. Fifty others are on order and by the end of this month most of an order of 2,000 will have been received.

A connection at Spartan of the abandoned part of the coal railroad division of the Chicago & Eastern Illinois will begin about Nov. 1. George M. Barnard, general counsel for the **Chicago, Attica & Southern R. R. Co.**, the recently formed corporation which took over the abandoned part, made the announcement.

Reduced freight tariffs on Canadian coal through all points of entry to North Dakota have been received from the **Great Northern Ry.**, as a result of negotiations opened by the state industrial commission. Canadian mines have promised to furnish North Dakota from 500 to 1,500 tons weekly.

The I. C. C. will reopen the **Utah Terminal and the Utah Railway case**, which involves permission to operate in interstate commerce as well as serve the coal properties in Spring Canyon. The Utah Terminal was denied permission to operate as an interstate carrier some time ago. The Utah Railway has taken over the line, but the commission still withholds its permission. The case is to be heard again at an early date. The I. C. C. has denied the petition of the **Ballard & Thompson R.R.**, Southern Utah, to operate as an interstate carrier. The road was constructed in 1911 and has operated chiefly as a subsidiary of the American Fuel Co.

Federal Fuel Control Notes

Amendment No. 1 to Service Order No. 25—The I. C. C. on Oct. 17 ordered that this be amended and supplemented in the following respects: (1) By adding to paragraph 4 thereof an additional proviso as follows: "Provided further, that from and after Oct. 23, 1922, the supply and distribution of open-top cars suitable for the loading and transportation of coal to wagon mines shall be subject to the following rule: Upon any day when any such common carrier by railroad is unable to supply mines upon its line with the required number of open-top cars, such cars shall not be furnished or supplied by it to any mine which customarily does not load or is unable to load such cars with coal within 24 hours from and after the time of placement until all mines upon the line of any such carriers have been fully supplied with such cars." (2) That the proviso in paragraph 5 of said order which deals with the return of cars under load other than coal, in the direction of the mine be amended to read: "Provided, that such open-top cars, after the discharge of the coal lading thereof, may be used for the transportation of road and building construction materials, etc., and materials for car and locomotive construction or repair, when the destination of such materials is in the direction of but not beyond the mine or mines to which such open-top cars are destined for coal loading, and when such use will not materially delay or otherwise the production and transportation of coal."

General problems affecting the coal-price situation are assigned to **F. R. Wadleigh**, in co-operation with the fuel distributor. Mr. Wadleigh also will give consideration to the matter of anthracite prices and distribution, to export and bunker coal; to Tidewater and New England coal supplies and to individual complaints as to prices charged. Technical questions relating to the use of coal will receive Mr. Wadleigh's attention.

Obituary

William T. Steger, sales manager for the Wells Coal & Mining Co., with headquarters in St. Louis, died recently at his home in that city. He had served for 23 years with this concern.

Phil Gloeckner, 40, for several years engaged in the coal business in Ft. Wayne, Ind., died recently at the home of his brother-in-law at Richmond, Ind., where he was visiting. He is survived by the widow and one daughter.

L. H. Curtis, prominently identified with coal mining in Utah, died in Los Angeles late in September, at the age of 75. Mr. Curtis was vice-president of the Standard Coal Co. and of the Salt Lake & Utah R.R. Co.

Association Activities

Northern West Virginia Coal Operators' Association

Action taken by the representatives of the association at the Cleveland conference, upon which a full report was submitted, was approved at a meeting of the association held at Fairmont on Oct. 13. C. H. Jenkins, vice-president of the Hutchinson Coal Co., who attended the Cleveland conference, was named as the official representative of the association at the Chicago conference which is to be held on Nov. 14.

There was much discussion, during the meeting, of the action of the B. & O. in delaying the regular car loading bulletin until October, regardless of the car shortage now existing. Operators have difficulty in ascertaining just what the car distribution is between regions and each field feels that other fields are being given preference. Under a resolution adopted at the meeting the association will act as a clearing house for the collection of complaints as to car service.

Full compliance with the request of the federal fuel distributor for daily reports was recommended by the adoption of a resolution in which it was pointed out that such reports could be made to show how serious the car shortage was, especially through the use of memorandum notations.

Publications Received

Permissible Explosives, Mining Equipment and Apparatus, Approved Prior to March 15, 1922. By S. P. Howell, L. C. Ilsley, D. J. Parker and A. C. Fieldner. Bureau of Mines, Washington, D. C. Technical paper 307. Pp. 21; 6 x 9 in.; tables.

Trade Standards in the Pump Industry. This is the second edition of this pamphlet gotten out by the Hydraulic Society, and contains some additional tables and explanatory data. Pp. 21; 6 x 9 in.

Tests of Gas Masks and Respirators for Protection from Locomotive Smoke in Railroad Tunnels with Analyses of Tunnel Atmospheres, by A. C. Fieldner, S. H. Katz and S. P. Kinney. Bureau of Mines, Washington, D. C. Technical Paper 292. Pp. 27; 6 x 9 in., illustrated.

Coming Meetings

Kentucky Mining Institute will hold its annual meeting Nov. 3 and 4 at Seelbach Hotel, Louisville, Ky. Secretary, Elizabeth C. Rogers, Lexington, Ky.

The National Industrial Traffic League will hold its annual meeting Nov. 15 and 16 at the Hotel Commodore, New York City. Secretary, J. H. Beek, Chicago, Ill.

Coal Mining Institute of America will meet Dec. 13, 14 and 15 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., 911 Chamber of Commerce Bldg., Pittsburgh, Pa.

National Exposition of Power and Mechanical Engineering will be held at the Grand Central Palace, New York City, Dec. 7-13. Manager, Charles F. Roth, Grand Central Palace, New York City.

Canadian Institute of Mining and Metallurgy, annual Western meeting Nov. 15-17, at Vancouver, B. C. Secretary-Treasurer, G. C. Mackenzie, Montreal, Quebec, Can.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, Editor

Volume 22 NEW YORK, THURSDAY, NOVEMBER 2, 1922 Number 18

Co-operating with Hammond Commission

PERHAPS nothing has contributed so much to the excellent start made by the U. S. Coal Commission as the very frank admission by its members that they know nothing about the problem they have had thrust upon them and their invitation to both the miners and the operators to jump in and help educate them. Meetings were held last week in order with representatives of the United Mine Workers, the soft-coal operators and the anthracite producers. Each was urged freely to give advice as to how the duties and functions of the commission as laid down by the law should be carried out.

A committee of the bituminous-coal operators seeking to represent not the National Association alone but the industry generally has offered full co-operation. The National Association has levied a special assessment on its members, to which others are to be asked to contribute, to raise a substantial fund to supplement that given the commission by law. That is to say, the bituminous-coal operators propose to contribute the money to finance important research work for the commission, the money to be spent by the operators at the direction of or in accordance with the suggestions of the commission. This, of course, is perfectly proper, for it simply amounts to carrying a step further than the mine office the collection of data requested by the government. The decision to devote its time and money to the assistance of the Coal Commission rather than fight it, to accept it as something that will be of ultimate benefit to the coal industry rather than looking on its activities as detrimental, is the most forward-looking step the National Coal Association has taken.

The United Mine Workers have taken the request of the commission in good faith and have already supplied a 7-page brief expressing their ideas as to the direction that certain parts of the investigation should take. They have suggested, for instance, that careful investigation should be made of absentee ownership, the spread between mine price and delivered price, the possible connection between coal companies and machinery manufacturers, discrimination by railroads in the placement of railroad cars at the mines, thus producing irregular employment, middleman's profits and of coal storage.

On the whole, this first document for the record (which we are pleased to note was broadcast to the press) is a series of suggestive questions and implications such as might easily have been compiled by any newspaperman or any citizen who had followed the subject in recent months. This communication and the others that doubtless will follow from the same source will serve to keep the public and the commission posted on what questions should be answered. Its apparent guilelessness detracts none from its interest and value.

The commission has a long, hard task ahead of it, and the very evident willingness of all parties at interest to help without restraint will make its work more certain of success. The friendly spirit that seems to prevail augurs for a happy ending.

Effect of American Demand On the British Coal Trade

UNDER the caption "The End of the American Coal Spurt" the editor of *The Compendium*, London, summarizes the effect on the British coal trade of the recent demand on this side for English coal. It is pointed out that buyers on this side did not leave the British long in doubt of their intention of taking only the coal that was urgently needed, and that by the middle of September inquiry was practically at an end and negotiations in progress were stopped.

As has been currently recorded in our market columns, the American demand caused a spurt in British coal production, forcing the weekly output well above 5,000,000 tons from around 4,500,000 tons. Exports climbed from 4,793,000 gross tons in June to 6,146,000 tons in August. Later figures are not as yet available. From practically none in June, the portion of these totals sent to this country rose to 930,913 tons in August. Our own figures show that 606,000 tons reached here during that month.

Prices were affected by the sudden onslaught of American buyers. Increases in quotations ranged from 2s. to 6s. 9d. per ton, according to quality. The peak in prices was reached in August, a marked slump being recorded in September. Ocean freights reached their peak in July. When the buying from this side began it soon developed that ships and not coal would be the limiting factor. The charter market responded with jumps of a shilling or more, only to subside when vessels from all over the Atlantic were offered for this trade.

On the whole the British coal industry has much for which to be thankful in the threatened coal shortage on this side inasmuch as it provided a sudden and unexpected market for several million tons of coal. The British coal industry had been in the doldrums for many months, wages had sunk to the legal minimum, prices were dropping and as they dropped the usual buyers were holding off waiting for the bottom. Mines had been closed and the men were suffering—even at the minimum wage the operators could not produce and find a market for their product. But when utilities, railroads and free-lance traders on this side drained off the surplus supplies and called for more, the coal industry in Great Britain took on new life. Continental buyers woke up to demand their share and the trade became brisk.

The impetus has not been lost. The strike on this side not only made a market on this side but rescued the miner on the other side from a winter of dullness

Excessive Taxation of Coal Lands

ANTHRACITE dealers and consumers, to say nothing of mine operators, would do well to study the evolution of a movement for the excessive taxation of coal lands, reported elsewhere in this issue. There is no desire to alarm, but there are things worse than being an alarmist—for example, being so optimist as cocksure that the most patent signs of the times are ignored or explained away.

The plain facts are that the anthracite industry in the lower field, where nearly all the reserves lie, is being subjected to the raids of taxation harbor whose program, if carried out, and whose underlying philosophy, if generally adopted, will speedily put the hard-coal business on the rocks. The present assault is, in many ways, the most serious of all those directed at the anthracite interests in the unremitting warfare of the last twenty years.

To raise a property for taxation at ten or twelve times what was paid for it or for what it will bring in the open market is nothing short of a levy on capital. It might be heard without surprise as a report from Russia, but as a report from supposedly conservative Pennsylvania it comes as a shock which should serve as a warning. A precedent which is made in the case of anthracite lands can be applied to other real estate, if not indeed to all other property.

Consumers of anthracite in markets like New York and New England justly aroused by the Pennsylvania State tax on anthracite tonnage, should by no means ignore the implications in the Schuylkill County situation. There a community of perhaps 250,000 which has now collected 65c. from coal-land owners on every dollar raised for general county purposes this year calmly proposes to increase the revenue 50 per cent and to collect 85c. from coal lands and only 11c. from the general community. The Schuylkill County proposals involve a much greater amount per ton than does the Williams tonnage tax of 1921, against which public officers in anthracite-consuming states entered a protest.

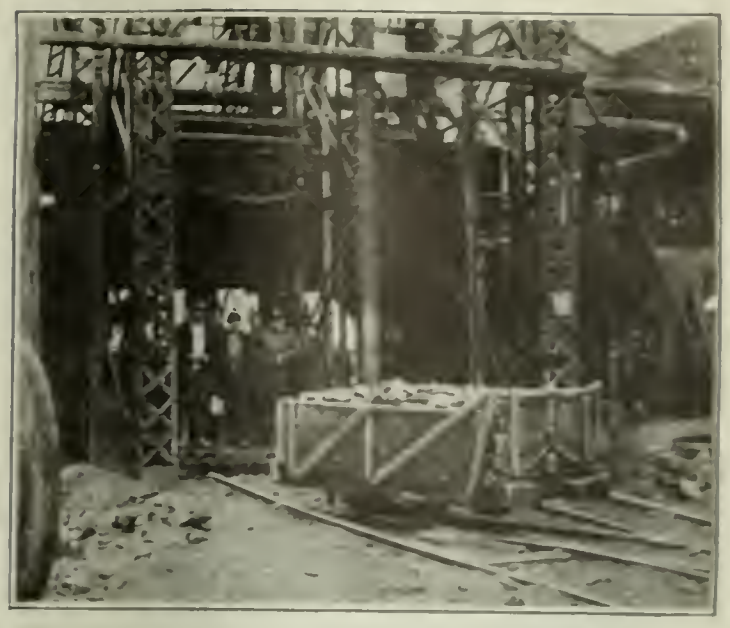
Consider the cumulative effects of Pennsylvania public policy with respect to the anthracite industry, the only American industry peculiar to that state. As long ago as 1916 Governor Brumbaugh's commission reported that new legislation and continuous investigation were among the causes for increasing coal prices. Yet the Pennsylvania Legislature has not only put a tonnage tax on anthracite—the only Pennsylvania product so treated—but it has burdened hard coal with hampering legislation like the Kohler act and the Fowler act, purporting to prevent mine caves, and raising millions, by another tonnage tax, to make good cave damage. Frankly discriminatory legislation of this character has heartened all those like the commissioners of Schuylkill and Northumberland counties to put all the traffic will bear on the backs of the coal companies in the shape of taxes.

One producing company in the upper region gives a rough estimate that its total tax bill—federal, state and local—amounts to about 80c. per ton of production. One producing company in Northumberland County last year paid, as county and municipal taxes alone, an amount equivalent to at least 25c. per ton. The new idea in taxation, if carried out, would double that figure this year.

These things are bad enough, but there is an even more dangerous idea buried in this systematic bleeding of anthracite owners. It is the implied, and even expressed, determination to tax in the present, potential wealth which should be, and is being, conserved for the future. If adopted, it means farewell to the sound policy of conserving natural resources, adopted by the federal government less than twenty years ago.

Anthracite is a stabilized industry. In normal times a year's production, working at approximately full time, merely meets the year's demand. There is normally no shortage in supply and no carry-over to speak of. If the hope of the shortsighted, with respect to excessive taxation, is carried out, and lands now held as reserves are forced into premature operation, the result will be too many mines, too many men employed, broken time, wildly fluctuating prices and alternate dearth and plethora of supply. In short, the tendency in this taxation scheme, whether deliberately intended or not, will be to bring about in the hard-coal industry the exact condition of overdevelopment which is considered one of the main faults of the bituminous industry.

When the President's investigating commission gets around to anthracite it might with profit delve into this matter of taxation as exemplified in Schuylkill and other hard-coal counties.



No Assigned-Car Decision

NO IMPORTANT significance is attached to the action of the Supreme Court in the Corona coal case. Acting on the precedent of the Lambert Run case, the court affirmed the decision of the District Court of northern Alabama in dismissing the suit of the Corona Coal Co. against the Southern Railway. No action was taken by the Supreme Court which in any way passes on the merits of the question involved in the practice of assigning cars. The court's action involved only the matter of jurisdiction. An effort had been made to bring the Corona case to the Supreme Court in such form that the country's highest tribunal could deal with the merits of the question, but the case reached the Supreme Court with exactly the same points involved, and the court in its ruling simply applied its action taken in the Lambert Run case.

The case arose during the car shortage of 1920 following the Interstate Commerce Commission's order modifying Rule 8 to define private cars and cars for railroad coal as assigned cars and all others as unassigned cars. The Corona company filed suit in the State Circuit Court at Birmingham, alleging discrimination against it in not being given a pro rata of assigned cars under the rating system after the company had offered to sell coal to railroads at a competitive figure. A temporary injunction was issued by the state court. The railroad company obtained a transfer to the United States District Court. This court dissolved the injunction and dismissed the suit on the ground that relief should have been sought from the Interstate Commerce Commission; that the attack was against the assigned-car rule and not against its application, it not having been alleged that the railroad delivered assigned cars contrary to the rule or that the order was unequally applied. The District Court held in effect that the railroad had not discriminated because it had delivered assigned cars according to instructions and had distributed unassigned cars among the mines in proportion to their ratings, although the supply was insufficient to meet fully the ratings.

How Rearrangement of Track Raised the Tonnage Of an Anthracite Colliery

By Dever C. Ashmead*
Kingston, Pa.

After Track Revision and Other Provisions Legitts Creek Coal Co. Dispenses with Five Men and One Mule and Quadruples Tonnage—Savings in a Year's Running Pays for All Reconstruction

DOES your track hold down your tonnage? Are you wasting effort in trying to hold up your output under unfavorable circumstances where a slight revision of the trackage as to line, grade and position of switches would not only make it unnecessary in handling trips to have close supervision and a nice co-operation between the men by whom the cars were being handled but would afford an increase in tonnage in a manner almost automatic? Wherever delays are occurring the subject is one worthy of consideration. An ounce of planning of a new track layout may save a full pound of effort in handling a badly adjusted track and give better service into the bargain.

The neck of a bottle determines the quantity of liquid that can be poured from it, or rather it determines the rate of discharge. The shaft or drift mouth, whichever it may be, together with the track arrangement at the bottom or the top of the shaft, constitutes the real neck of almost any mine.

Obstructions or ill-conceived track arrangements may limit the output of a colliery beyond hope of betterment, for no more coal can be prepared and shipped than can be delivered to the outside or to the breaker. A mine may be able to produce and load into mine cars 2,000 tons a day, but if the track arrangements are such that only 500 tons a day can be sent to the surface then the capacity of the mine is limited to that quantity.

About three years ago the Legitts Creek Coal Co. purchased the mine at Scranton, Pa., that it is now operating. At the time of purchase the output was about 200 mine cars of coal and forty of rock. The mine was awaiting the happy thought as to surface tracks that would bring its tonnage to a profitable figure, for a small tonnage means a heavy cost. Previous foremen had labored in vain against the insuperable difficulties of a faulty layout.

The coal was brought up through three openings—two shafts and one slope. One of the shafts is right at the foot of the dragline conveyor which leads to the breaker. The other is about 200 ft. distant. The slope mouth was about 400 ft. from the second shaft and its top was about 50 ft. lower than the elevation of the top of the shaft. The coal from this slope was taken on the surface to a short tunnel and through this tunnel to the shaft, where it was hoisted 50 ft. to the surface.

From the shaft to the foot of the dragline conveyor that feeds the breaker is about 200 ft., as has already been stated. About 100 ft. from the shaft the rock track left the main roadway. The grade on this track was insufficient to cause the rock cars to clear the coal cars, and the rock cars collected on the track between the junction point and the top of the shaft. The map shows at this point only the new tracks and the old rock switch consequently is not visible, but it was located at the point marked *A* on the plan. This layout naturally caused congestion and reduced the quantity of coal that could be hoisted, as no more coal could be handled on the surface than could be passed over the track to the dump. At No. 2 shaft no rock at all could be hoisted, as there was no connection between this shaft and the rock dump. Therefore all this rock had either to be hauled underground to No. 3 shaft or unloaded by hand underground, which latter was a slow, expensive operation and one that caused congestion of the mine tracks.

At No. 2 shaft the distance from the shaft to the

*Anthracite Field Editor, *Coal Age*.

ARRANGEMENT OF ROCK TRACKS FROM SHAFTS

A, loaded rock track from No. 2 shaft; *B*, empty rock-car track to No. 3 shaft; *C*, track to ash pocket; *D*, empty rock-car track to No. 2 shaft; *E*, loaded rock-car track from No. 3 shaft

PLAN OF TRACKS AT LAFOLLETTE COAL MINE

dump is about 15 ft. and the cars were run off the cage, dumped and immediately hauled back by a small hoist.

The ashes from the boiler plant are run out on the rock dump and dumped at that point. These cars also tended to cause congestion at the foot of the plane on the rock dump and therefore delayed the handling of the rock cars.

With conditions such as these the output of the colliery could not be greatly increased by any degree of supervision, co-operation or dexterity. Some track changes were absolutely necessary. One of the great difficulties was the lack of space around the tops of the shafts. The locations of these shafts, and those of the bottom of the plane to the rock dump and the coal dump were alike fixed almost beyond revision. This meant that the rails of the tracks could not be moved whatever other changes might be made.

The handling of the rock was the most serious trouble encountered, but this difficulty was corrected with comparative ease. The rock track which connected with the loaded coal-car track at *A* was changed to connect at *B*, and this gave about 100 ft. more rock track. The grade was increased so that the rock cars would run away from the shaft by gravity. This greatly relieved the congestion at this point.

At No. 1 shaft a switchback was provided so that rock cars could be hoisted at this shaft (with the end gate facing the breaker as usual), run through the switchback and then to the foot of the rock plane with the end gate now facing the rock dump and away from the breaker. The rock cars from this shaft are removed from the cage in the opposite direction from the coal cars and now handle themselves by gravity. A new track was laid from the rock bank to No. 2 shaft for the return of the empty mine cars, and the way it connects with the cage track likewise is shown in the accompanying plan.

Another cause of congestion was the handling of ashes from the boiler house. In order to meet the difficulty a dragline conveyor was built to remove the ashes from the ash pit and convey them to an ash pocket which will hold as much as will accumulate in two days. These ashes can now be handled when there is not much rock, and their handling does not interfere in any way with the production of coal. This ash arrangement has another advantage in that it is not necessary now to handle ashes during Sundays and nights, for the ashes can be stored in the ash pocket, and thus it is not necessary to pay men to haul ashes on those occasions.

Another important change was in the empty track from the coal dump to No. 3 shaft. Here the car haul was raised 3 ft., and the gradient from the top of the car haul to the shaft thus increased, so that the cars move more freely. The curves were taken out, and the services of a driver and mule were eliminated.

The method of handling the cars from the slope to the surface also was changed. Instead of bringing them all the way to the surface through the slope they came only to the Four-Foot bed. They are then taken underground to No. 3 shaft and then hauled to the surface by that shaft. This has saved a surface haul such as interferes with operation in the winter. It also saves a mule and a driver on the surface.

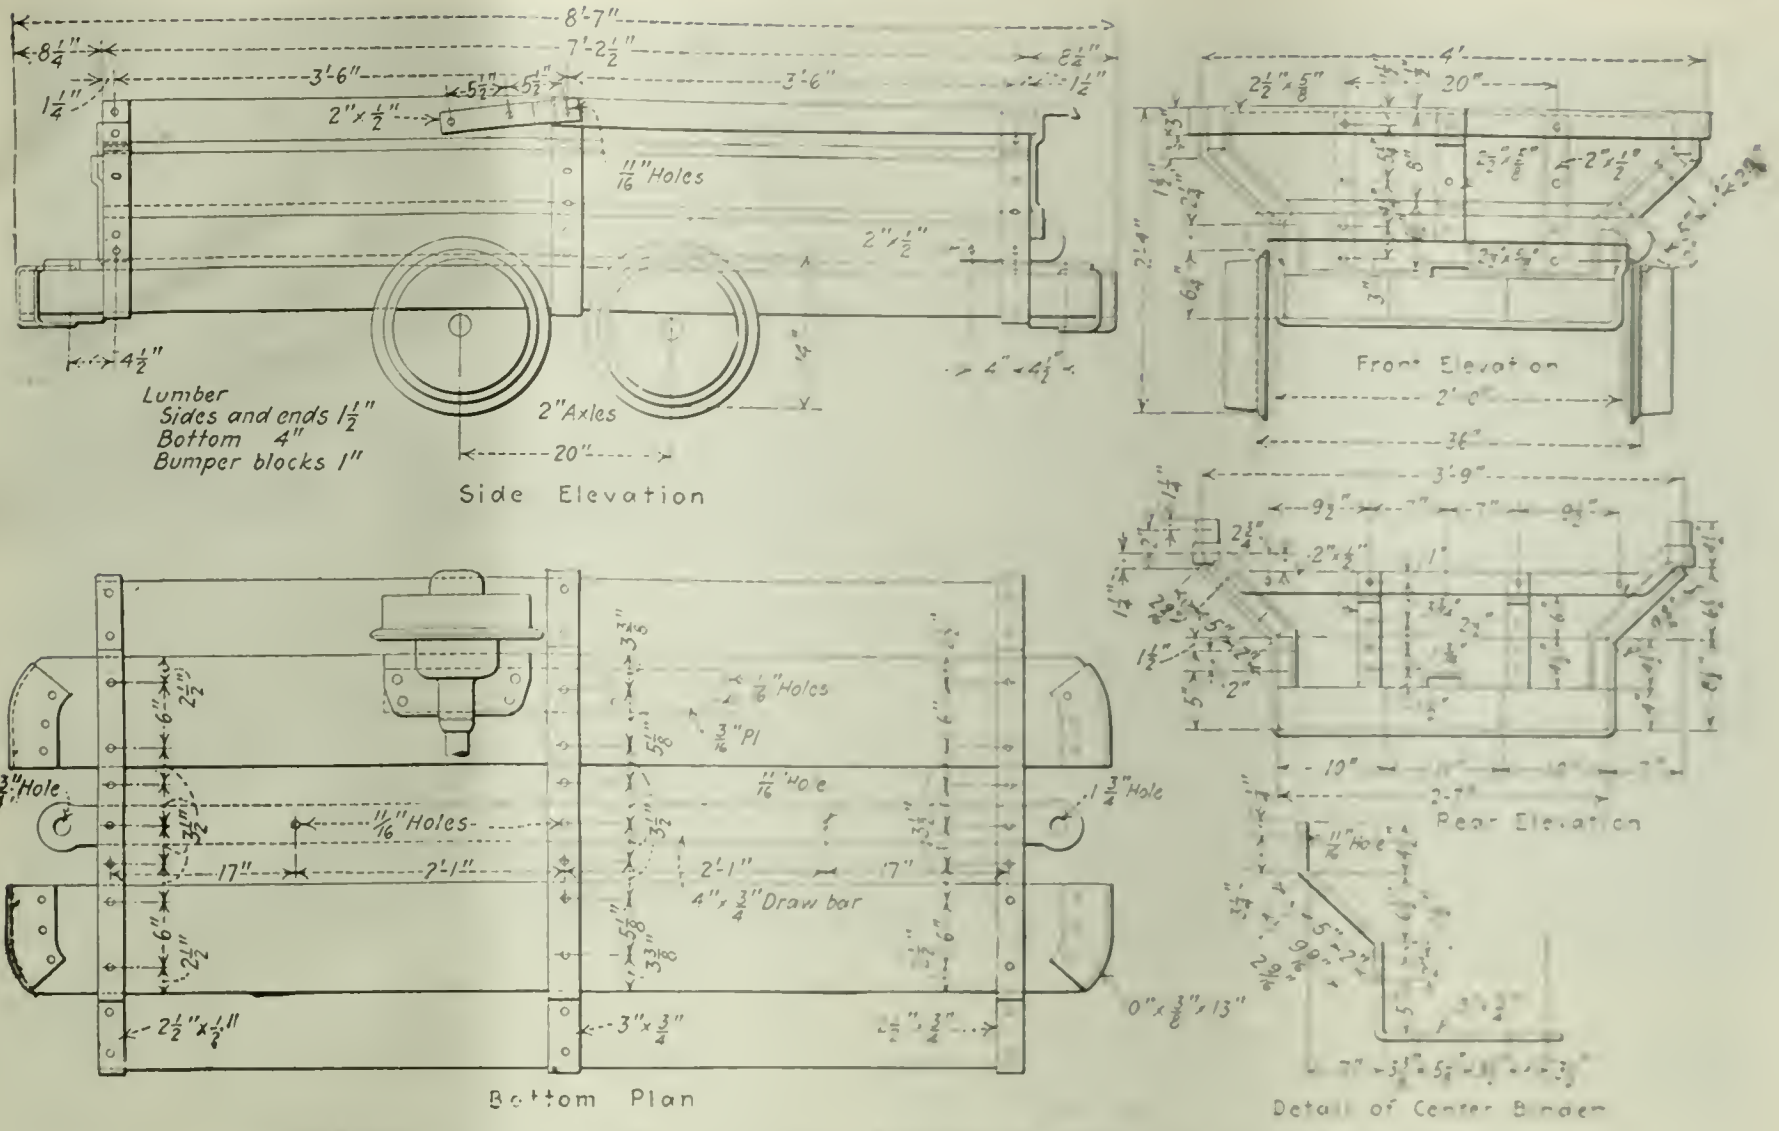
The method of handling supplies to the mine also was changed. Instead of sending them into the tunnel that has been mentioned a new track was laid to connect with the empty car track to No. 2 shaft, the supplies being hauled to the shaft level by a small hoist.

The changes that have been outlined were, on the whole, inexpensive, but they saved five men and one mule. Therefore the saving in labor alone in a year's time would about pay for the cost of the changes, but not only is money being saved but the obstruction to the neck of the bottle was removed, and the output of the mine could be increased.

After three years of operation the output of the mine has risen from 200 cars of coal and forty cars of rock to 800 cars of coal and 100 cars of rock.

Improved Mine Car Decreases Costs

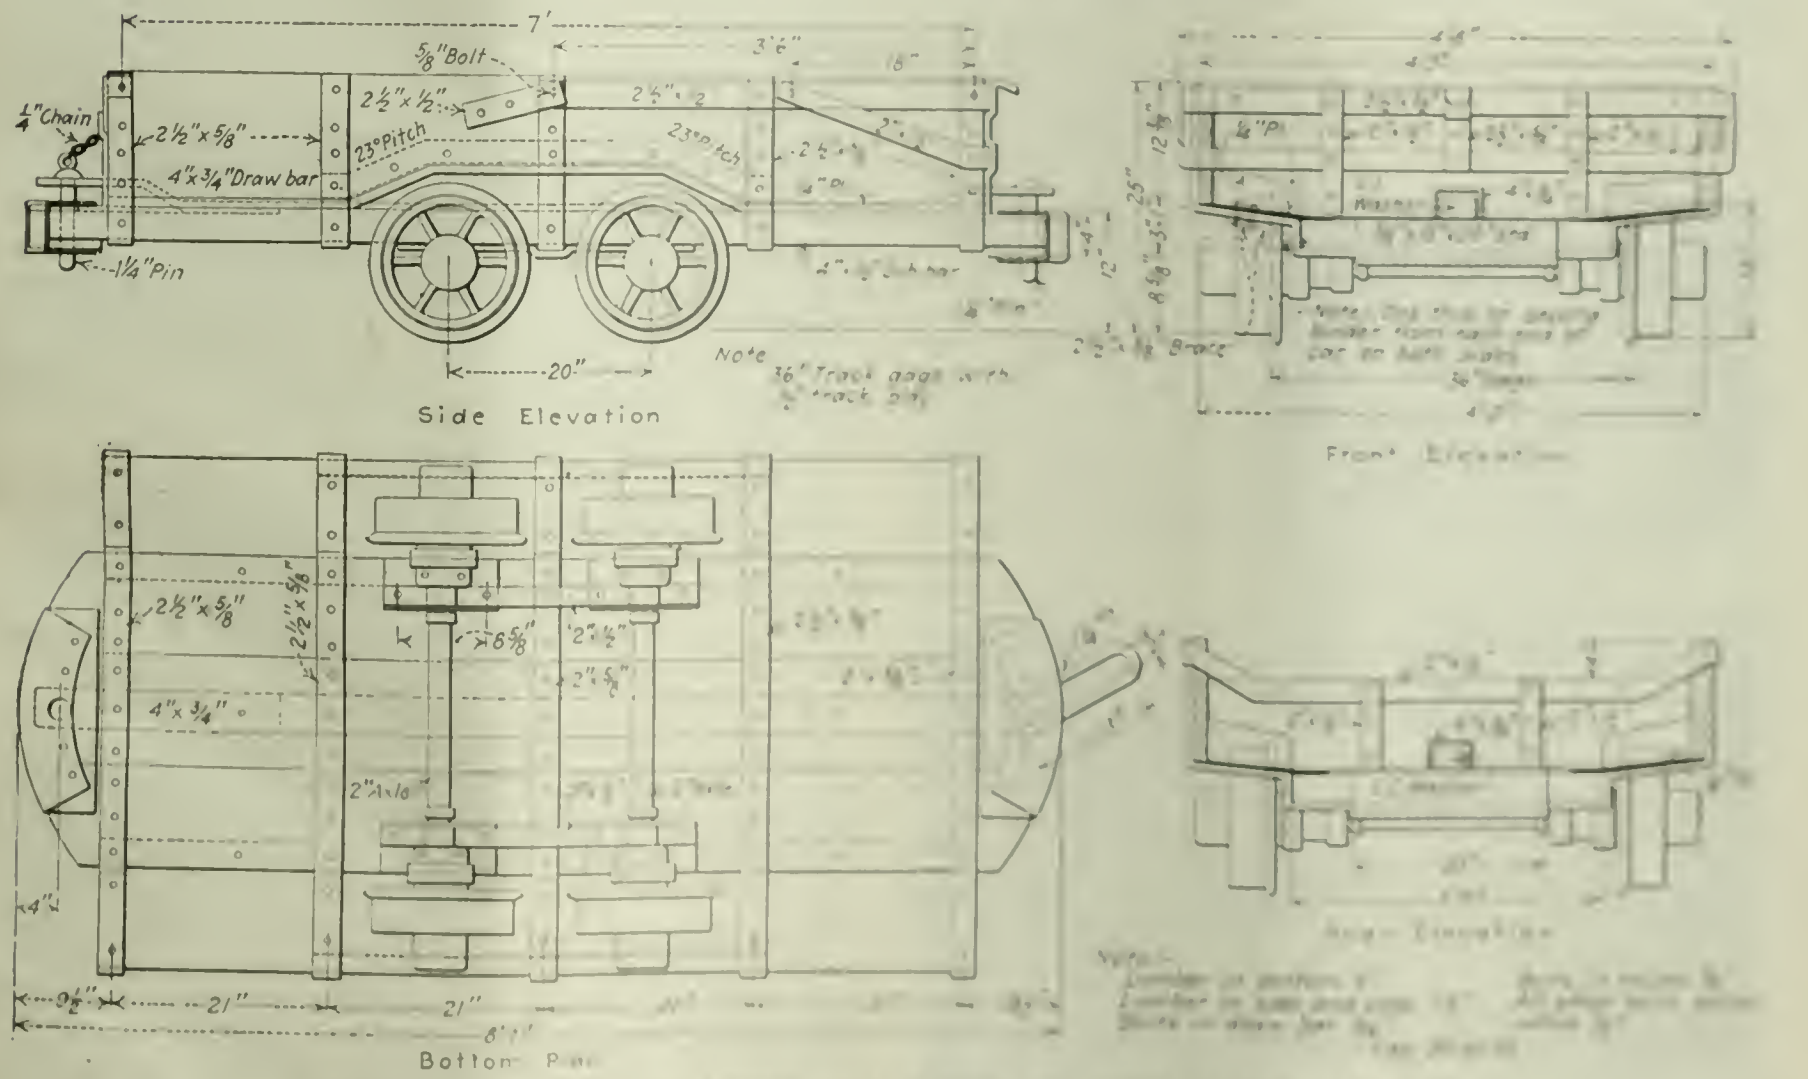
By L. C. Crewe*



EVER since mining began mine cars have been mine cars, yet each succeeding year witnesses improvement in this type of mine equipment. The interest manifested in underground transportation clearly denotes the importance of this phase of coal production.

In the accompanying illustrations Fig. 1 shows the car used until recently by the La Follette Coal & Iron Co. The Rex coal bed worked by this firm averages 42 in. in thickness and, as may be seen, this car was 28 in. high above the rail and held an average of 1,840 lb. Its weight was 1,640 lb.

Fig. 2 shows the new car designed by this company's engineers and now used in place of that shown in Fig. 1. In gage, wheelbase and length over bumpers the new car is identical with the old; its over-all height, however, is 3 in. less and its width 8 in. greater. The new car weighs 1,820 lb. and its capacity is 2,540 lb.



Notwithstanding the increased size and weight of the

*Consulting Engineer, La Follette Coal & Iron Co.

FORMER CAR OF LA FOLLETTE COAL & IRON CO. FOR USE IN A 12-IN. [illegible]

The car is only 28 in. high and it has the flare which for many years satisfied those who departed from the square box type of car which preceded it. The inside width on top is only about 3 ft. 5 in. and at the bottom only 2 ft. 3 in. These facts account for its meager capacity.

PRESENT CAR OF LA FOLLETTE COAL & IRON CO. WITH LARGE CAPACITY

In this car the wheels are placed so that [illegible] over the wheels so as to admit of this arrangement. [illegible] and about the same as the former, permitting the [illegible] wheel protector is carried [illegible]

new car the miners report that when loaded it can be pushed over wooden rails with greater ease than could the older one on steel rails. Of course any improvement that gleans the miner leads toward cost reduction. Furthermore a locomotive can haul as many of the new cars as it could of the old, about thirty constituting a trip. The only additional expense is the slightly increased actual power consumption. It is estimated that haulage costs have been reduced about 25 per cent by simply changing the design of car. The first cost of the new car is practically the same as that of the old design, so that no greater investment is required.

Coal from Behring and Chickaloon Fields, Alaska, Will Be Used on Battleship

RECENTLY the naval collier Jason started en route from Alaska with 5,000 tons of washed coal from the Chickaloon mine and 600 tons from the mines of the Behring River Coal Co. This coal is to be given a test on a battleship. John Hazard, one of the fuel engineers attached to the U. S. Bureau of Mines, will assist in the tabulation of the results.

An application of gold-mine practice has been resorted to in washing the Behring River coal. Gold sluices have been put in for this purpose and are giving splendid results. They are built in parallel, so that while one is being cleaned the other is in service. The plan is so effective that even the fine coal, which settles in the bins, shows no more than 4 per cent ash. Much of the coal thus far mined has run only 2 per cent in ash. The coal is sacked at the foot of the sluice and then transferred by truck to a canoe landing 4½ miles away.

The truck runs over a type of plank road that has been used so successfully that the plan is being adopted elsewhere in Alaska and may play no inconspicuous part in the expansion of motor haulage in the territory. The road is laid directly on the tundra. Heavy slabs are laid down for crossties. In lieu of rails a 3-in. plank 12 in. wide is spiked to the crossties on each side to form the track for the trucks. Guide rails have been found unnecessary and even in wet, slippery weather no difficulty has been experienced in keeping the trucks on this type of roadway. This particular road has been in service for three seasons and it has been found that the cost of maintenance is insignificant. The original cost was $6,000 per mile. A plank road in the Katalla oil fields nearby was built twenty years ago and still is in service.

TRUCKING BEHRING COAL TO CANOE LANDING

Slabs are laid on the tundra and a runway is made of 3 x 12-in. planks laid on their flats and spiked to the slabs. On these planks, unprotected by a guard rail, the truck runs 1½ miles.

Some Hoisting!

SEVERAL months ago *Coal Age* requested information concerning hoisting and production records. Many replies were received and published and much interest was manifested in the results. One great difficulty in considering such data is that it is seldom that the lengths of cage travel in any two cases are the same or even closely similar. This renders a basis of equitable comparison difficult.

Charles F. Sherman, general superintendent of the Groveland Coal Mining Co., Peoria, Ill., writes that on Oct. 16 at Groveland No. 2 mine 274 hoists were made in 60 minutes. The total length of hoist or cage travel at this operation is 202 ft. and the cars hold a net weight of 3,000 lb. of coal.

With cars holding only 1½ tons of coal each, Groveland No. 2 can hardly expect to compete in output with some other operations regardless of the excellence of its hoist or the skill of the engineers that drive it. So far as *Coal Age* is aware, however, the above figure stands as a record so far as actual number of hoists performed in one hour is concerned. If any mine can beat or has already bettered this number, we would be glad indeed to hear about it.

Inspector Exonerates Lake Creek Miners

IN A RECENT letter W. L. Morgan, State Mine Inspector of the twelfth inspection district of Illinois, writes saying that the unofficial report on the explosion at the Lake Creek mine of the Consolidated Coal Co., near Johnston City on Friday, Sept. 29, in which five were killed and two injured was wrongly ascribed to two miners who were alleged to have been smoking pipes. Mr. Morgan has reported to the Director of the Department of Mines and Minerals that the explosion was due to the surveyors igniting a body of gas in entries that had not been working for two or three years. These entries were in about 300 ft. from the main entries. Owing to a chain of circumstances the ventilation had been short-circuited in these headings. The explosion that ensued ignited a cartridge of powder and then a keg of powder, part full. The explosion occurred just as one miner was loading his car and the other sitting on a pile of coal. The miners were not in any way to blame.

The Mine Blacksmith's Tools and How He Uses Them

Mounting the Anvil—Three Cutting Tools—Flatters and Set Hammers—Fullers and Swages—Punches and Tongs—What They Are Made Of—How They Are Tempered and How Kept in Condition

By Gustav A. Radebaugh*
Urbana, Ill.

EVERY official around the mines should know something about blacksmithing, for much of the successful operation of a mine depends on the prompt and efficient performance of this department.

In Fig. 1 is shown the various parts of the common anvil. The best anvils are made with a wrought-iron or soft-steel body and a face of tool steel about ¾ in.

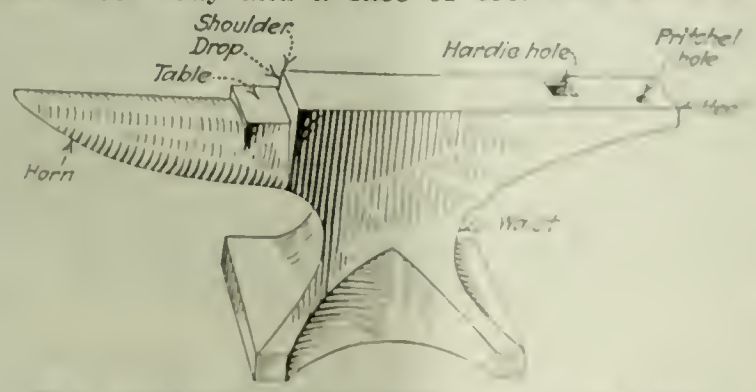


FIG. 1—PARTS COMPRISING A COMMON ANVIL

The pritchel, or prickle, hole is used when making holes in iron or steel. The stock is held on the flat of the anvil and the punch driven till it is about two-thirds through. Then the stock is reversed and held over the pritchel hole and the punch driven through from the face thus made uppermost.

thick. The horn and table are not so faced, however, and they are said consequently to be "dead." They do not wear nearly as well as they would if they were faced with tool steel. The size of the anvil is not rated by its dimensions, as being so many inches long or wide, but by its weight, and this weight is marked on the face of the anvil in three numbers. The first records the weight in even hundredweights, the second the excess in weight in quarter hundredweights over the nearest lower even figure and last the excessive weight in pounds over the nearest lower even figure for quarter hundredweights. The usual weight of an anvil for shop use is between 100 and 150 lb. The pritchel and hardie holes are used to hold tools in place and also serve for the making of bends.

The anvil is mounted on a solid wooden block, preferably of oak, hedge* or ash. It should be cut square

*Osage orange.

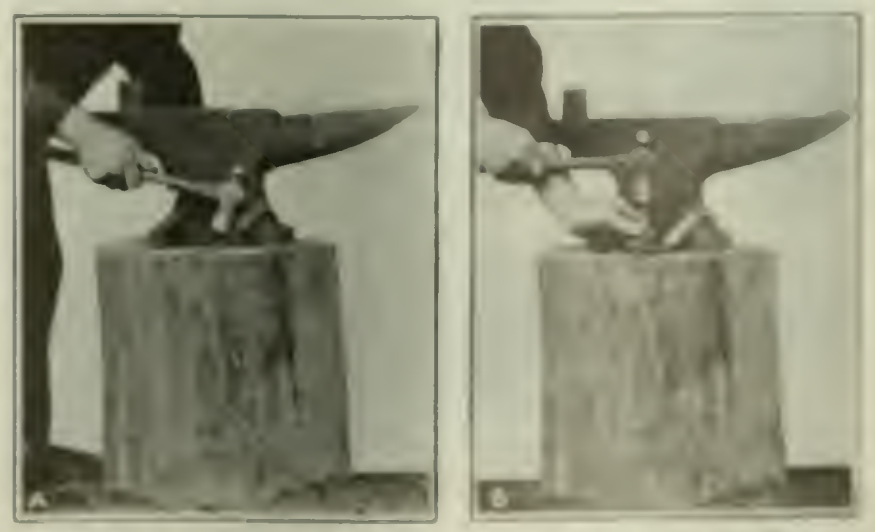

FIG. 2—ATTACHING THE ANVIL TO THE WOOD BLOCK

Effective as is the wood block, nothing better has been found. The spring that the wood gives is a desirable quality, as it imparts a certain liveliness to the anvil.

*Mechanical engineering department, University of Illinois.

NOTE—The headpiece shows a blacksmith shop at the Delaware Colliery of the Hudson Coal Co.—a regular power hammer and a makeshift, two forges, a grindstone and a water backet. Published by courtesy of Ingersoll-Rand Co.

FIG. 3—HOT CHISE

FIG. 4—COLD CHISEL

The hot chisel should not be used on cold work for it does not retain its temper and the edge will bend over. The cold chisel is shorter and thicker than the hot chisel on its cutting end. As a rule it is tempered harder also.

FIG. 6—FLATTER

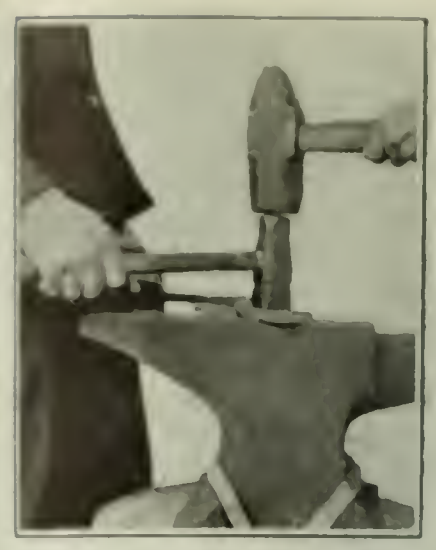

FIG. 7—SET HAMMER

The flatter and set hammer permit the making of bends without leaving hammer marks on the stock thus forged. The material should be worked at a dull red heat and the tool dipped in water before use.

on each end and should be about 20 in. long. The anvil should be at such a height that a man standing erect and doubling the knuckles of his hand could just touch the face. It should be set 5 ft. from the center of the forge and directly in front of the fire and the floor should be well leveled before the block is placed in position. A piece of ¾ x 1½-in. soft steel is secured and bent around the waist of the anvil as shown in the illustration. After this steel has been shaped to the outline of the anvil a ½-in. hole is drilled in each end to receive the holding-down spike.

The anvil should be placed in the center of the block, and the strap should be spiked to the block. Though one of the simplest methods for securing the anvil it is one of the best. A wooden block is the best mounting for an anvil, as it gives the necessary cushion for the solid mass of steel. It helps to liven up the tool and makes it much easier to work on. The anvil should be placed so that the horn is to the left of the operator.

Three cutting tools are commonly used about the forge and anvil. The "hot chisel" is used for cutting hot metal. As shown in the view, the tool is held by the smith and the helper strikes the tool with the sledge. When cutting hot metal the chisel should be dipped in water after receiving several blows from the sledge. This is done to prevent the cutting edge of the tool from becoming heated to such a degree that all the temper will be drawn from it and the chisel become so soft that the edge will bend over. Under ordinary treatment the hot chisel does not hold its temper and this is why it should never be used on cold work.

For Heavy Cutting Dip Cold Chisel in Oil

The cold chisel shown in Fig. 4 is used in the same manner as the hot chisel, but the cutting edge is of a thicker cross-section. It is designed so that heavy blows from the sledge can be delivered without injury to the cutting edge. Compare the two chisels as shown in Figs. 4 and 5. It will be noted how much shorter and thicker the cold chisel is on the cutting end. In using this tool in cutting heavy sections the edge should be dipped in oil, which will assist in keeping the edges keen.

The hardie, Fig. 5 *A* and *B*, is set in the anvil by inserting its stem in the square hardie hole. It should fit the hole loosely enough so that it will not stick or wedge tight. It is used for light cutting and for trimming hot or cold work. The hardie for hot work is drawn out to a thin edge, but that which is used for cold work is much thicker. The edges are designed somewhat like those of hot and cold chisels, respectively.

In illustration *A* is shown how a piece of stock is placed on the hardie to be struck by the hammer. When cutting stock a deep cut should be made around the material. The stock is then placed on the edge of the anvil as shown in illustration *B*. A few blows with the hammer will then break the stock. It will be understood that the material in this operation is worked cold.

FIG. 5—HARDIE SET IN ANVIL CUTS LIGHT IRON

The view at the bottom of cuts must not vary. The marginal lines show that a hammer and a sledge is used. Cuts are made all around the stock, which is finally broken off in the manner shown at *B*.

The hardie, it will be noted, is a one-man tool, but though it has this advantage over a hot or cold chisel it has the disadvantage that it cannot be used for large work. All three cutting tools are forged from 0.7 to 0.8 per cent carbon steel. The temper should be drawn to a light straw color. When the cutting edges become worn or blunted they can be ground or redressed and tempered. The spoke of an old buggy wheel makes excellent material for the handles of all forging tools that are to be made of wood.

In forging work many tools are needed if a job is to be properly finished. The flatter and set hammer (see Figs. 6 and 7) are used for practically the same purposes—smoothing and flattening work. By using these tools when the material to be forged is at a dull red heat and dipping the tool in water before it is applied to the work, all the rough scale can be removed from the surface, thus leaving a smooth, finished appearance. When making a stock-gate hinge a right-angled bend is made, as shown in Fig. 6. It is good practice in this instance to use the flatter instead of a hand hammer. A more even bend can be made and the surface of the stock will not be made uneven by hammer marks. Flatters for general work have a face from 2 to 3 in. square. The edges of the face are slightly rounded, and because of that provision the tool will leave no marks on the work.

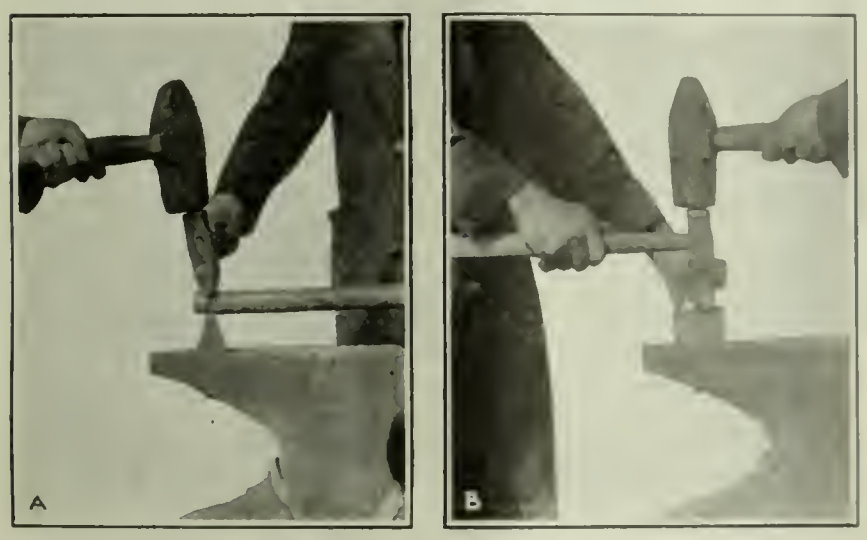

FIG. 8—TOOLS USED FOR MAKING ROUNDED GROOVES

A shows the top and bottom fuller, the latter fitting into the hardie hole. *B* shows another view of these tools. The top fuller is sometimes used alone for making scarfs for welds, for forming grooves, smoothing fillets and forming shoulders on only one side of the forging.

The set hammer is shown in Fig. 7 making an offset on a strap iron. When an offset of the thickness of the stock is desired a piece of the latter is placed on the anvil, and the strap iron is laid over this piece as shown. The work thus offset is then forged into shape by the aid of the set hammer and sledge. The set hammer is useful also when squaring up right-angled bends. These hammers are made with faces from 2 to 2½ in. square.

The top and bottom fullers and top and bottom swages (Figs. 8 and 9) are made in pairs. The bottom parts of these tools are designed to fit in the hardie hole and the tops are provided with handles. As shown in the view, the forging blow is delivered by a sledge, the tools being held in a stationary position. Fullers and swages are both sized by the curved edges. A fuller with a curved edge of ½-in. radius would be termed a 1-in. fuller, as the curved edge would be the same shape as one-half of a 1-in. bar.

The fuller is made in several sizes. The top and bottom fullers are used for forming depressions or shoulders on opposite sides of materials, as shown in Fig. 8. They will also be found useful when drawing out metal between shoulders or projections. The top fuller is sometimes used singly in making scarfs for welds, forming grooves, smoothing fillets or forming shoulders on only one side of the forging.

FIG. 9—SWAGE

FIG. 10—PUNCH

The swage rounds up work or forges round shapes to a smaller size of correct semicircular cross-section. After a rod is welded the swages are used to smooth the weld. Punches are made of octagonal or round steel, tapered toward the working end but slightly flared or relieved at the point.

The swage (see Fig. 9) is used for rounding up work or forging round shapes to a smaller size. When forging stock to a circular section the swages are conveniently used for smoothing up after the stock has been drawn to about the correct size. After welding a rod the swages are used to smooth up the weld.

When Tool Mushrooms It Should Be Redressed

If an extra-smooth job is desired the top swage can be dipped in water occasionally. The operation is known as "swaging." These tools are not tempered and the best grades of them are made from drop forgings out of 0.8 to 0.9 per cent carbon steel. After these tools have been in severe service the head of the tool mushrooms, and chips of steel may fly when the tool receives a blow from the sledge. This can be avoided by redressing the head of the tool. To redress these tools, remove the handles and work the steel at a cherry-red heat. After the operation is complete, permit the head of the tool to cool slowly by placing it in ashes.

The small repair shop uses two methods of punching holes in hot metals—the hand punch and one of a heavier type, as shown in. Fig. 10. This latter punch is provided with a handle and driven by a sledge. The hand punch is made from octagonal or round tool steel and is about 8 in. long. The end is forged to a taper

FIG. 11—HOLLOW-BIT TONGS ARE SHAPED TO STOCK

This tool is heated before use and not cooled. When bright red the jaws are closed upon the piece to be held and are forged so that they will hold it tight. In the illustration the workman is not forging the stock but the tongs by which the material to be forged is being held

FIG. 11—HOLDING SQUARE STOCK IN TONGS

Stock should be held end of a few points but throughout the entire length of the jaws of the tongs. Note how carefully the tongs must be shaped for this. A link slipped over the handles will keep a grip on the stock, and all the blacksmith will have to do will be to press the check to work the tongues.

and is made of the same shape but a little smaller than the hole to be punched.

When punching, as shown in Fig. 10, the hole is started by laying the work flat on the anvil and driving the punch about two-thirds through it. The work is then turned over and the punching is continued from the other side. The hole can be located easily by the bulge in the metal caused by the punching already accomplished. When the punch is driven through, the work is held directly over the round hole, as illustrated in Fig. 10. If the hole is punched in this manner it is left clean and to size.

When punching thick stock, after the punch is started the tool is removed and the hole filled with powdered

FIG. 12—PREPARING BOLT FOR WELDING TO NUT

The tongs are heated and hammered to fit snugly on the stock for the full length of the jaws. After the bolt is heated the end is upset on the anvil face to thicken it and the nut and rod are welded on.

coal. This prevents the punch from welding. Tools of this kind are tempered and they should never be left in the heated work any length of time, as the end will become soft and will enlarge in the hole, which makes it nearly impossible to withdraw it. This enlargement is called "upsetting." The size of these tools is determined by the size of the hole which the punch will make.

When an irregular shape, such as is shown in Fig. 11, is to be forged, it is necessary to take a pair of hollow-bit tongs and heat the jaws to a bright red. The jaws of the tongs are then forged to fit the piece of stock which is to be held. Sometimes the rivet in the tongs tightens up in this operation. This may be relieved by first cooling the tongs and then delivering several blows with the head of the hammer on the head of the rivet, which is held over the hardie hole on the anvil.

The best method of holding square stock is shown in Fig. 12. The tongs have been heated and hammered to fit the stock. In holding stock it is important that the tong jaw fit throughout its entire length. This type of tong is used to hold round stock as well as square. In holding the larger sizes of stock a link can be slipped over the handles. This will relieve the workman from the work of gripping the tongs tightly and allow him more freedom in handling the material.

When welding a head on the end of a rod to make a bolt, the stock is held in the hollow-bit tong, as in Fig. 13. The tong jaws should fit down on the stock snugly so as to insure easy handling of the piece while it is being forged. To make a special bolt, first cut the stock to length, then heat and round up the end of

FIG. 14—SPECIAL TONGS MUST BE USED FOR LINKS

These tongs are carefully fitted to the link that is to be welded. They are not used to hold the link in the fire because they would get too hot. When the broken link is at the right heat it is seized by the tongs and rapidly hammered into a continuous ring.

the stock, fit on the blank nut and then weld the nut and rod together. After this operation is complete, cut the thread and the bolt is complete. Using the proper tongs for a welding job of this kind makes the operation much easier and insures a better weld.

The link tong, shown in Fig. 14, is an essential when welding chain links. It is made in such manner that its jaws can be heated and fitted to the link that is to be welded, for only a well fitting tong will hold the link securely. When heating the link to a welding heat, hold it in the fire with a small rod until that heat is reached. The link tongs should be used only to remove the piece from the fire when the weld is to be made and

FIG. 15—FORGING THE HANDLES FOR READY HOLDING

Sometimes when the tong jaws are not properly offset the handles are so far apart near the ends that no human hand could grasp them. In that event the handles must be bent so as to correct that failing. The illustration shows this being done.

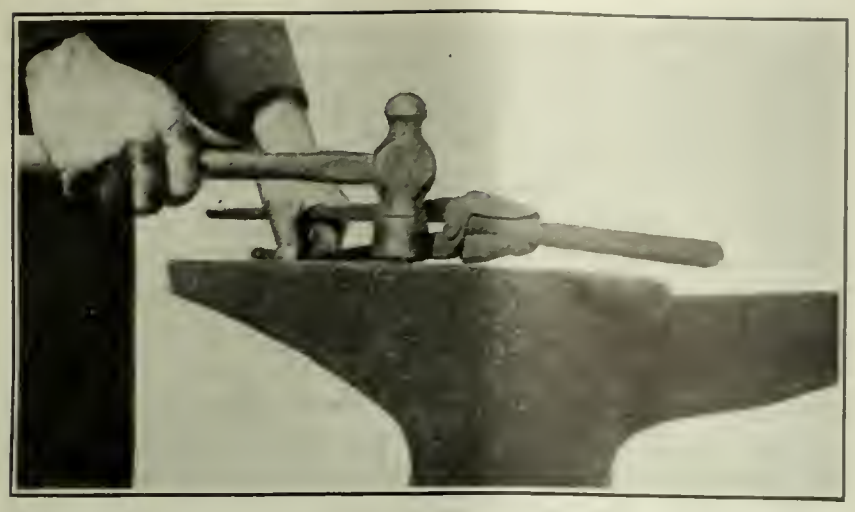

FIG. 16. BOX TONGS FOR FLAT OR ROUND MATERIAL
The tongs have a wide mouth which makes it possible for them to grasp a large piece of metal without causing the handles to diverge too widely.

during the making of the weld, for if they are used during the entire heating operation they will be heated to such a degree that they will not hold the link. This, however, applies only to smaller sizes of tongs.

In bending a short piece of steel to make a wagon-bed brace the stock is held while being heated and forged with the flat-jawed tongs (see Fig. 15). These tongs are made in various sizes to hold different thicknesses of stock. In using tongs the handles should be far enough apart only to permit the smith to grip the handles without unnecessary reach. When the tong jaws are not sufficiently offsetted and so are too close together for the stock to be securely held the handles are so far apart that it is impossible to hold them with one hand. This can be adjusted by placing the tong handles on the horn of the anvil as close to the rivet as is permissible and bending the handles to the center until the proper distance is obtained.

When forging a short piece of stock it should be securely held if the best results are to be obtained. The box tongs shown in Fig. 16 are found useful in many repair jobs, as they are designed to hold square or round stock so that it will not slip when being forged. It is important always that tongs should have and maintain a firm hold on the material forged.

Suggests Standard Shatter Test for Coke

COMPARISON between the strengths of cokes and the determination of the strength a coke must have to serve for certain purposes make it necessary to standardize the shatter test. To this the Committee D-5, on Coal and Coke, of the American Society for Testing Materials, of which W. A. Selvig, of the U. S. Bureau of Mines, is secretary, has addressed itself.

The committee suggests that the box for holding the coke in this test shall be 18 in. wide, 28 in. long, approximately 15 in. deep and shall hold about 50 lb. of coke. It shall be supported above a rigidly mounted cast-iron or steel plate not less than ½ in. in thickness, 38 in. wide and 48 in. long. The inside of the bottom of the box shall be 6 ft. above the plate.

The bottom of the box shall consist of two doors hinged lengthwise and latched so that they will swing open freely and not impede the fall of the coke. Boards about 8 in. in height should be placed around the plate so that no coke will be lost. To prevent breaking the material when filling the box, the latter shall be constructed so that it can be lowered to a convenient level, which is best done by means of a pulley and counterweight. For determining breakage of coke, square-mesh screens with the following openings shall be used: 2 in., 1½ in., 1 in. and ½ in. Circular screens 2 ft. in diameter are satisfactory for this purpose.

For byproduct coke when determining its freedom from breakage in handling, about 75 lb. of representative pieces of coke, none of which would pass in any position through a 2-in. square-mesh screen, is to be selected from the coke wharf for each test. This is best accomplished by dividing the coke on the wharf into approximately equal areas and selecting an equal number of pieces from each area. Each piece selected shall be approximately equal in length to one-half the width of the coke ovens and should show a "cauliflower" end produced at the walls of the ovens, and an "inner" end produced at the center of the ovens.

For beehive coke, when determining freedom from breakage in handling, about 75 lb. of representative pieces of coke shall be selected for each test as the coke is drawn from the ovens. This is best done by selecting full-length pieces, or their equivalent, as the coke is being drawn from previously determined points in the oven, so that they include pieces from the front, sides, center and back. If the individual pieces as taken from the ovens are too large and bulky, the 75-lb. sample shall be collected by removing three small pieces from each large piece—one from the top, the middle, and the bottom. The sample finally collected should be composed of an equal number of pieces showing top, middle and bottom. None of the pieces comprising the sample shall in any position pass through the 2-in. square-mesh screen.

For byproduct and beehive coke, when determining their fitness for furnace or cupola use, the sample is best collected as the coke is delivered from the railroad cars into the bins. This may be accomplished by inserting a scoop of 10 to 15-lb. capacity in the coke stream at regular intervals during the period of unloading. The sample collected shall be large enough to give about 75 lb. of coke pieces, none of which would pass in any position through a 2-in. square-mesh screen.

As it is difficult to collect a representative sample from coke exposed in bins and cars, care should be taken to take pieces representing the entire exposed area, if sampling must be done in this manner. This is best accomplished by dividing the exposed surface to be sampled into approximately equal areas and selecting an equal number of pieces from each area. Approximately 75 lb. of representative pieces, none of which would in any position pass through a 2-in. square-mesh screen, shall be collected.

About 50 lb. of the sample shall be placed in the shatter-test box, the coke leveled, the box raised, and the coke dropped four times on the plate, the small material produced being returned each time to the box with the large coke. After the fourth drop the material shall be successively run through the screens described.

In screening, care should be taken to prevent breakage of the coke pieces. The screen shall be shaken gently until all of the pieces are in direct contact with the meshes. The coke remaining on each screen, and that which passes through, shall be weighed separately. If the sum of these weights shows a loss of more than 1 per cent the test shall be rejected and another made.

As the average probable error of a single shatter test is approximately 2 per cent it is advisable to make several tests and report the average result.

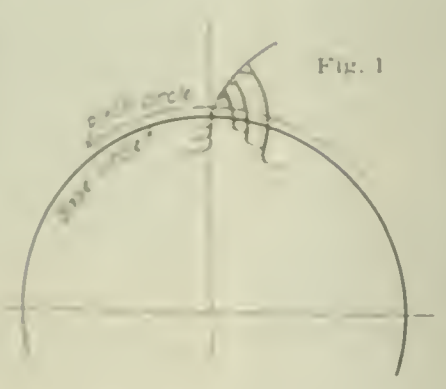
Gear Economics Effected by Use of New Tooth Shapes*

By R. E. Sawtelle†
Cincinnati, Ohio

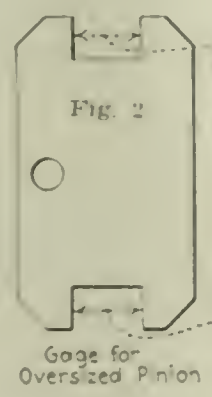
For many years stress was laid almost exclusively on improvements in the quality of the steel used in locomotive gears, but in recent years more emphasis has been laid on tooth shape and on the possibility of constructing better gearing through appropriate design. Any teeth of correct profile will give satisfactory service when new, but we must concern ourselves mainly with the service that the teeth will afford when, in course of time, they have become partly worn.

Until recently practically all locomotive gears had the Brown & Sharpe 14½-deg. standard tooth, which operated smoothly, was of a full depth and therefore had more wearing surface than the stub teeth. Being comparatively straight sided, it showed less tendency to push gear and pinion apart. This 14½-deg. tooth is a general standard, easily interchangeable and almost universally used for industrial machinery. The chief objection to it is the fact that when pinions thus formed have a small number of teeth the teeth are undercut in the flank, making them thin and likely to break near their roots. Furthermore this fault, objectionable as it is in new teeth, tends to accentuate as such pinions wear.

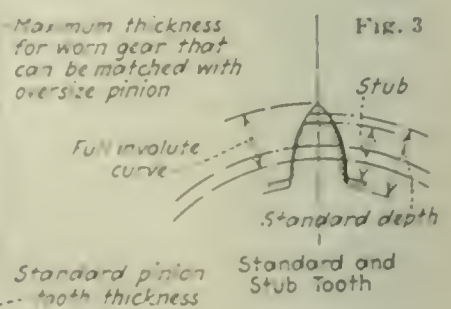
The first improvement used in the railway field was the 20-deg. stub, a tooth which is not so deep and which, therefore, gives the teeth on the opposing gear less leverage on the base of the teeth it drives or by which it is driven. It has accordingly less tendency to break, its sides, moreover, are more slanting and it is provided with a broader base. A 20-deg. stub tooth, therefore, has great strength and, because of its lesser depth, the pinion is strengthened somewhat against bursting, particularly where the bore is large and the pinion small.



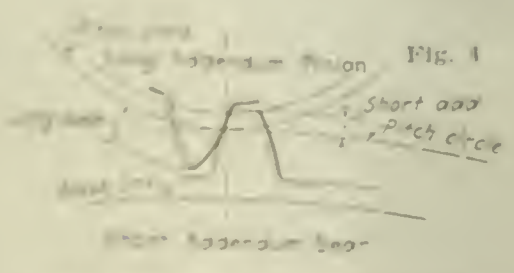
The next development was the long- and short-addendum tooth, a type of gearing that for years has been used extensively for railroad service in European countries, particularly Germany and Switzerland, and has been adopted in America for many years in bevel and automotive gear. Its application to the electric-locomotive field was delayed primarily because it lacked interchangeability with teeth cut to the old standards.



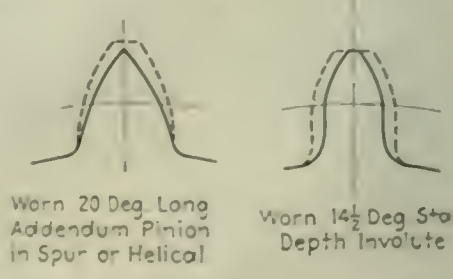
This type of tooth usually is made with a 20-deg. angle, which broadens the base and increases the strength. Furthermore, by shifting the addendum, the pinion tooth, usually the weaker member of the train, is considerably strengthened, and this is done without weakening the gear. By making the diameter of the pinion contain the quantity of metal between the root of the tooth and the bore is increased and thus it is strengthened at a point where it is often weak and likely to break. This type of tooth when cut full depth is rather thin at the top and as a result for this the tooth is sometimes stubbed. The stubbing process removes metal that would otherwise be worn away in service, hence it has a tendency to decrease the life of the pinion, but it makes a more pleasing appearance.



To understand the significance of the long- and short-addendum tooth, we will need to go slightly into theory. The involute curve is the base of practically all our modern gearing, as it represents the ideal curve of contact when two gears are in mesh. Fig. 1 shows three left-hand involutes generated from the same base. The section between the right- and the left-hand involute is a gear tooth, needing only to have the top trimmed off and the bottom shaped up to continue into adjacent teeth.



The farther apart the involutes, the coarser the pitch and the less teeth in a gear of any fixed diameter. The full involute, however, is too long for practical use, so a section is taken out of it for the individual gear tooth. If this section is close to the base circle, as at *A*, Fig. 6, we have practically the straight-sided tooth of very low pressure angle, which is used where there must be no thrust between gear and pinion. Coming up higher on the curve, as at *B*, we have the 14½-deg. pressure angle, heretofore standard. Higher up, as at *C*, we have the 20-deg. tooth, and to illustrate by an extreme case, as at *D*, we could build a gear with about a 30-deg. tooth and yet one which would work smoothly but with a heavy thrust and which would be of no value at all when considerably worn or used with bad bearings. High pressure angles therefore mean forming a tooth on the upper part of the involute curve, farther removed from the base circle. In a gear with many teeth slight changes in pressure angle are hardly measurable, but in a pinion with few teeth they are quite noticeable.



The dimension chosen as the standard depth of tooth is purely arbitrary. In Fig. 3 we have the full involute, which runs to a point at the top. We first decide the pressure angle we prefer to use, and this choice determines how high up we shall locate our pitch line on the involute curve. If we take a comparatively long section above and below this line, we have the full-depth standard tooth. If we take a lesser section above and below, we have the stub tooth. If we take a greater section above the pitch line than we take below the pitch line we have a long-addendum pinion, and when we build the

LOCATION OF PITCH CIRCLE RELATIVE TO STRENGTH AND WEAR

Fig. 1—Development of heavy and low pitches on same base circle. Fig. 2—Gage for oversized pinion. Fig. 3—Stub and standard teeth. Fig. 4—Long- and short-addendum teeth. Fig. 5—Long-addendum tooth when worn is still strong at the base

*Abstract of paper presented before Cincinnati Electric Railway Association.

†Assistant general manager, The Standard Gear & Tooth Co.

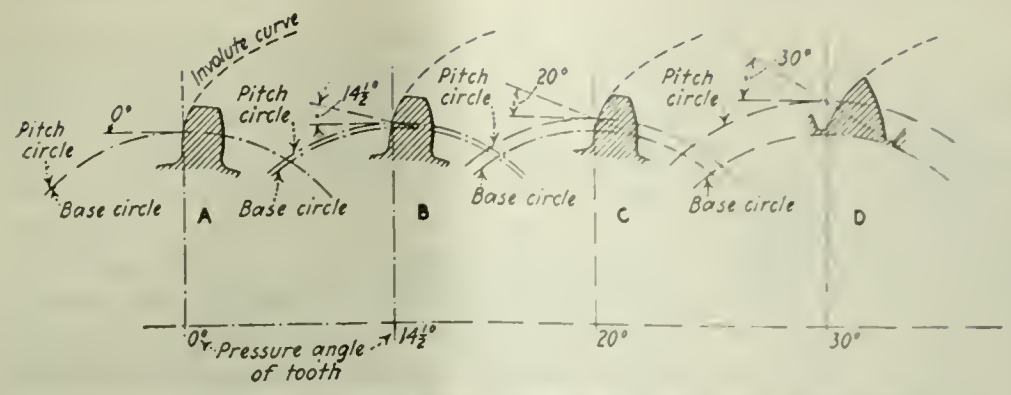


FIG. 6—FOUR TEETH WITH SAME PITCH AND VARIANT PRESSURE ANGLE

Shows plainly how the shape of the teeth will vary when the pressure angle is changed. An extreme case is shown in the right-hand tooth, where the pressure angle is 30 deg. The normal tooth is the second in the row. It has a pressure angle of 14½ deg.

gear to match it we must make it with a correspondingly short addendum.

In standard gearing the relative size of the tooth and slot is the same on each member. In long-addendum gearing (Fig. 4) the teeth are made much longer on the pinion and project further beyond the pitch diameter. On the gear the slot is deepened proportionately. Likewise on the gear which mates with this pinion the tooth projection is shortened and the slot in the pinion is correspondingly shallow.

The amount of diversion in extra length and depth is optional with the manufacturer, and he can build around any formula he desires. The longer the addendum on the pinion the more pointed it will be at the top of the tooth. In Fig. 4 the addendum of the pinion is made of extreme length so as to make the contrast between long addendum and standard gearing the more noticeable. The long-addendum pinion is preferable to the standard for the reason that it is a stronger pinion at the base and a thicker or "fatter" pinion at the pitch line. In actual service twice as much steel may be worn off the side of the tooth with safety before rejection with the long addendum than is permissible with the standard 14½-deg. shape. This is illustrated in Fig. 5. When worn out it is still a strong tooth at the base, whereas with the old shape the root tends to weaken more rapidly as the result of wear.

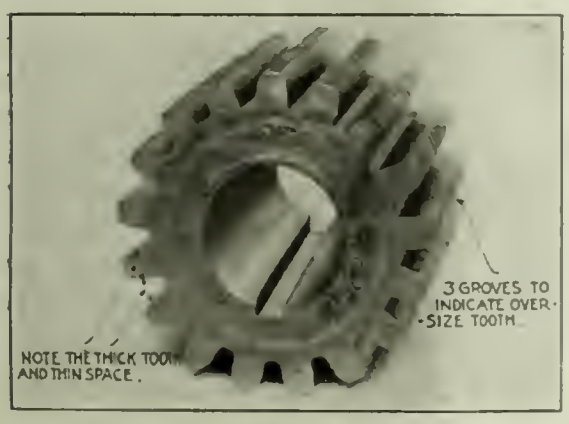

FIG. 7—OVERSIZE PINION

Will mate only with a worn gear. Space is made thin and tooth thick.

This means that if a long-addendum pinion and a standard pinion of equal quality are operating under identical service, the long-addendum pinion, because of its tooth shape, will have approximately twice as much life. The gears running with these pinions will have about equal durability; in fact, only by accurate measurement can you distinguish between the forms of the short-addendum and the standard gear tooth. There is no question whatever as to the desirability of the long-addendum pinion for any service where gears and pinions are to be completely worn out before they are discarded. The only drawback is the seriousness of changing over from the old standard to the new.

The "wisdom-tooth" pinion was recently brought out to overcome this difficulty and to present the operating man with a practical opportunity to realize all the advantages of long- and short-addendum gearing without making any radical change or expending much money. The wisdom-tooth pinion (Fig. 8) is in every way a long-addendum pinion and partakes of all its advantages. It is, however, so designed and generated that it can be operated with the standard Brown & Sharpe 14½-deg. gear.

Hence it can be installed without any gear change, and the operator can go over to the true form of long- and short-addendum gearing with all its advantages by merely renewing pinions with those of the wisdom-tooth shape. There is no dark secret about this profile; it is purely an involute generation of a standard tooth on an oversized-diameter blank. Its use, however, involves one slight change—that is, a slight reduction in the ratio as one tooth is dropped out of the pinion when the wisdom tooth is adopted. The changes in speed and acceleration caused by the different ratio are so little noticed that, for instance, street cars in railroad work equipped with "wisdom teeth" are running on the same schedule as cars with standard pinions and even in one case are running in multiple-unit trains interchangeably. In another instance wisdom-tooth pinions have been put on motors on one end of the car and standard pinions on the other with reports from the mechanical department that this gives thoroughly satisfactory service.

Wisdom-Tooth Pinions Stop Breakage Trouble

To illustrate the close similarity between the wisdom-tooth and the standard long-addendum tooth Fig. 8 (a) shows the one superimposed on the other. The oldest wisdom-tooth pinions have been in service more years than comprise the average life of standard pinions and still are only one-third worn out. In several cases they have completely stopped what was otherwise serious breakage trouble.

A still further and successful innovation is the "oversize" pinion of either standard, wisdom-tooth or long-addendum design. Whether this shall be used is also purely a practical problem. When an automobile cylinder and piston rings become slightly worn they are replaced with new oversize piston rings. Likewise, when a gear is badly worn it can be mated with a pinion having thicker teeth than the normal standard. This takes out the major part of the backlash and uses the old gear under much better operating conditions than normal.

At the same time, as the oversize pinion has thicker teeth at the start, more material can be worn off them before they are reduced to the scrapping point. The

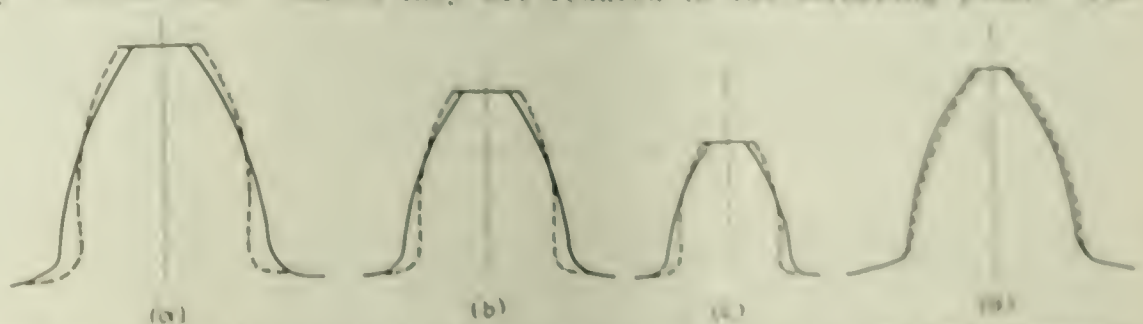

FIG. 8—WISDOM TEETH (HEAVY LINES) SUPERIMPOSED ON STANDARD TEETH

A wisdom-tooth pinion has one less tooth than the standard pinion for the same pitch, but the change makes little difference in operation.

FIG. 6.—PINION OVERSIZE; PINIONS HAVE A TOOTH WIDTH AT PITCH LINE LARGER THAN THE SPACE

When a gear is badly worn it can be meshed with a pinion having thicker teeth than is normal. By this means much of the backlash is avoided and the service of the old gears is improved.

teeth, being thicker, are stronger at the root, both when new and worn out. The advantages therefore are that the pinion wears longer and has greater strength and less backlash. The only disadvantage is that care must be exercised not to mesh oversize pinions with unworn gears. The manufacturer guards against this mistake by marking them with three peripheral grooves, illustrated in Fig. 7, and by using a wear gage to ascertain whether the gear tooth is worn sufficiently to work satisfactorily with the oversize pinion.

An Argument in Favor of the Steel Grid*

BY A. F. PHILPS†
Parkersburg, W. Va.

OPERATING conditions in the coal-mining industry are perhaps more trying to resistance boxes than those found in any other work in which they are employed. To meet these difficulties experiments into the possibility of using rolled-steel resistances instead of cast grids were started some ten years ago and have continued down to the present date. Tests have been made as to the best alloy to be used for that purpose, the best method of supporting the grids, the best kind of insulating tubes, the preferable method of ventilation and other problems relating to the construction of such grids.

Cast-iron grids, being made of small cross-section, are liable to break when subjected to rough use, and sudden changes of temperature also are likely to fracture them. It has been said that more failures arise from the latter than from any other cause. It is easy to see that this latter defect cannot exist in a rolled-steel grid of any reasonable construction and even when broken by violence a steel grid can readily be repaired at the mine. A large company in West Virginia which had one hundred locomotives spent more than $20,000 in one year repairing cast grids whereas the rolled-steel resistors, of which it had several, needed no repair in the same period. Originally designed solely for mine locomotives, they are now used for street cars, hoists, cranes, large alternating-current motors, railroad turntables, steel-mill motors, coal-cutting and coal-loading machines and as ballast resistance for storage-battery locomotives—in short for all machines subject to severe operating conditions.

HARD STEEL ONLY IS USED

Rolled-steel grids are made of Homanite steel and have a resistance of 400 ohms per mil-foot. This steel has a high silicon and a high-carbon percentage and is so hard that holes are punched in it only with difficulty. The method of punching having been developed after years of experimental work.

The rolled-steel grid has been so completely standardized that it is said the repair parts that have to be carried are only 15 to 20 per cent of those needed where cast grids are employed. What is equally important, the 6½x6½-in. grid is adapted for use with all locomotives. The grid has no loose ends or loops and has seven supporting rods which not only hold the grid but prevent its buckling. Mica tubes are used for insulating the grids. Each rod is insulated from the end frame.

In considering the use of grids of more expensive construction it must be remembered that a grid is a part and only a part of a large and expensive machine and that it is not a wise economy to use a grid that may cause a machine to be laid off. Furthermore, as the grid is but a part of the machine so a locomotive is a part of the equipment of a mine, and the laying off of the locomotive may be a source of much contingent expense and reduction of output. The electrician tries to avoid this loss by cutting out part of the resistance or by working the locomotive after the resistance is in part cut out, but that is not a safe way of operating. When the resistor is kept in condition a real saving is effected on armatures, controller parts and gears, and one company has found that with steel grids, armature burnouts were reduced 50 per cent.

*Abstract of paper prepared for submission to the West Virginia Mining Institute. Mechanical and Electrical Engineering Association of Mine, Mechanical and Electrical Engineers. The paper in brief summarizes the conclusions in the report of the committee on "The use in mine locomotives of resistance grids made of rolled-steel plates as compared with cast grids," which was presented June 21 at the meeting in Huntington, W. Va. This article was published in the issue of Coal Age of June 14, pp. 1047-1049.

That Elusive Proximate Analysis of Coal

EVERYBODY knows that the constituents of coal are ill-named in the proximate analysis. What is termed fixed carbon, says the American Society for Testing Materials in its book of Tentative Standards, 1922, "is made up principally of carbon but contains also appreciable quantities of sulphur, hydrogen, nitrogen and oxygen." Some of these elements do not appear in the volatile matter or in the moisture yet are lost to the ash and so are grouped with the fixed carbon.

Volatile matter does not include moisture and whatever else may pass off below 105 deg. C. but does include incombustible matter given off in further stages of heating. Much of this is moisture. Ash consists in part of oxygen not contained in the coal and does not contain some of the constituents of the true ash of coal such as the water of constitution in clay. As the same authority declares, "The ash as determined" in the standard methods "is less in quantity than that of the actual constituents of dry coal owing to chemical changes which occur in these by burning."

"Sulphur in coal," quoting again the authority just mentioned, "although commonly reported with the proximate analysis, is not correctly a part of it, being elementary and of definite composition. Sulphur, moreover, is distributed in the proximate analysis as a constituent of two or more of the ingredients thus determined." It is not impossible that in some cases it is found in all four.

Some of the Surprises Which American Mining Congress Exposition Held for the Operating Coal Man

Hudson Company Shows Loree Breaker Model—Bearing Ball in Perfect Balance—Rough Way of Handling Shovels—Weighing Coal on a Running Belt—Box-Car Loaders, Fans, Pumps, Cages, Gears and Drills

COAL mining was the major theme, running through not only the program but also the machinery exposition, at the twenty-fifth annual convention of the American Mining Congress which was held in the new Public Auditorium at Cleveland, Ohio, Oct. 9 to 14. This was so marked that one or two exhibitors who were not making any effort to reach the interest of coal-mining men were moved to say that the exposition was a wonder—for coal. Locomotives, drills, shovelers and loaders, cars, pumps, ventilating systems—practically the full equipment of a coal mine was on display in about 150 booths both on the main arena floor and in the broad basement of the magnificent building. Never had the annual mine equipment exposition held forth in such handsome surroundings. The attendance was reasonably heavy but gave the impression of being less because of the vastness of the building.

The usual number of striking features drew the popular as well as the technical eye—and ear. The Hudson Coal Co.'s model of the Loree anthracite breaker occupied its usual spotlight location, attracting much attention as it went through the operations of handling hard coal. A cross-section of the mine itself, illuminated within, showed interesting points at each mine level, giving the uninitiated a good idea of the way a hard-coal mine would look if the earth were sheared down to the mine and one side of the section removed. This display weighs 12,000 lb., fills an express car and is attended by a crew of five men.

Smaller by 11,999 lb. 15 oz., but almost as memorable, was a single Atlas ball from an SKF ball bearing. Shot upward through a tube by air pressure the glistening little steel globule descended upon a 10-in. steel plate and bounced there for two minutes—always striking the same spot, thus illustrating its perfection of form—until inertia settled it upon the plate, when a gentle air blast rolled it into a trough which directed it into the air gun for another flight. This unique exhibit was much discussed.

Proving Resilience of Molybdenum Steel

Noise makers in the exhibition were the General Electric hard-rock drill working industriously on two 1,000-lb. blocks of stone and a glass-sided shovel-testing machine shown by the Wood Shovel & Tool Co. Shovels clamped to stout spokes on a rimless wheel revolving inside a drum incessantly dug their way through a pile of cobbles, putting over the idea that Wood molybdenum steel shovels stand a tremendous amount of racket, wear down uniformly and do not crack under frequent reverse bendings. The rattling roar of Westinghouse and General Electric gathering motors with their wheels mounted on rollers, the occasional shriek of Federal electric sirens for mine signaling and the lesser clank and whirr from lighter exhibits lent a busy sound to the exhibit from first to last.

One of the outstanding exhibits was that of a Merrick conveyor weightometer in action. One of the machines of standard size for the continuous automatic weighing of conveyor-handled materials was exhibited and was inspected by a steady stream of men who ascended a flight of steps to a small platform beside the "integrator box" containing the sensitive mechanism which was recording the weight of gravel passing on a belt. The weightometer can be installed on any belt conveyor, thus eliminating weighmen. A section of the belt is supported on a floating platform hung on compound levers, balanced by an iron float in a cylinder of mercury. The movement of the float is a direct measure of the weight on the conveyor belt. The float tips a roller-edged disk whenever a load goes over the belt. This disk is a part of the integrator, which multiplies the weight by the speed. A belt driven by the conveyor rubs against the rollers at the periphery of the disk. When this disk is perpendicular to the plane of the belt (the no-load position) the rollers revolve and exert no turning effort on the disk. When the disk, which is carried in a swinging frame, is tipped a component of motion of the belt acts to turn the disk. The greater the weight on the conveyor, the greater the tip and the faster the disk revolves. A simple mechanism records this motion after the manner of a gas meter. The weightometer is made by the Merrick Scale Manufacturing Co., of Passaic, N. J.

Rubber Insulation for Mine Power Cables

"Made like a cord tire," is the phrase that stuck in visitors' minds after they had seen the cable exhibit of the Rome Wire Co. Rubber insulated cables of nearly all sizes both in that booth and the display space of the Simplex Wire & Cable Co. were of interest because they had not been seen previous to a year ago. Heavy rubber insulation applied under pressure was put to all sorts of abrasion and kinking tests to show that cords and cables thus protected are built for heaviest coal-mine service whether used on a drill, a cutting or loading machine or a cable-reel locomotive. The cost may be twice that of ordinary braided cable but the service—many a mining man went away from the show with a new idea of the toughness and serviceability of good rubber insulation.

A lesson in quick loading of box cars with a minimum of coal breakage was taught at the Ottumwa Box Car Loader Co.'s display, where a model of an electric-driven pusher type loader was shown in action, illustrating the ease with which coal can be delivered clear into the ends of box cars without benefit of shovel and without the machine delay incident to the entry of a scoop gang into the car.

Modern ideas as to ventilation were set forth by the American Blower Co. and the Buckeye Blower Co. by an exhibit of reversible mine fans, capable of either blowing or exhausting, and booster fans to be used deep in the workings of a mine and especially with flexible

tubing such as that shown by E. I. du Pont de Nemours & Co. and the Hewitt Rug Co. With such tubing blind risers and working faces can be thoroughly and quickly ventilated where otherwise much time would be lost waiting for smoke and gases to clear.

Though pumps were shown by several companies, it remained for the Deming Co., showing a triplex horizontal 8 x 8-in. pump taking only 30 in. of headroom, to remember the pump maintenance man by featuring a valve cap hinged at one side and clamped down on the other by an eyebolt attached to the valve shell. Thus the cap can be lifted for pump cleaning and inspection without dropping a nut or washer into the muck.

A new type of all-steel self-dumping cage, which cannot dump in the shaft, was shown by Robert Holmes & Brothers, Inc. It is a type now being built for its first installation early next spring. The cage is heavier than most others on the market and is built to withstand severest service. The bed of the cage is supported on 15-in. structural steel beams, the rocking arrangement being made of heavy cast steel. With a 7-ft. platform such a cage will weigh 8,000 lb. Larger sizes will be made upon specification.

Novel equipment for handling coal in and out of storage with greater speed and less installation and operation expense than that incurred in the use of the average bridge crane attracted considerable attention in the exhibit of the Railway & Industrial Engineering Co., which now makes the Harrington Rocking Cableway. The construction is similar to that of any other standard cableway except in one important feature—its head and tail masts can be rocked in unison through an arc of 120 deg. Thus if the carriage is operating a clamshell bucket it can pick up or deliver coal over a wide area instead of merely along a single line, which is all that can be done when the masts are vertical and the cable line stationary. With 100-ft. masts the field of operation may be 180 ft. wide. The power consumed in rocking under load is greatly reduced by counterbalance weights.

Worm-Gear Speed Reducers Safe and Economic

An adventure in gears into the coal-mining field got its start at the exposition in the Dravo-Doyle Co.'s exhibit of Cleveland worm-gear reduction units. These worm-gear drives, designed for other uses, are now being applied to power transmission on picking tables, conveyors or any other comparatively slow, steady-moving machinery. Operating in an oil bath exactly on the principle of a worm gear in the rear transmission of a motor truck these units are expected to gain a foothold in mining because they occupy only about one-tenth the space of spur gears or belting and, being enclosed in a cast-iron case, they are protected against dirt and grit and do not tempt workmen to leave off the safety guards which are supposed to be bolted over drives of gears but which so seldom stay there.

A time and labor saver for roof drilling was a stoping drill shown by the Cleveland Rock Drill Co. This one-man machine had a bit that rotated at regulated speeds by an air turbine. The machine is operated without needing the usual aid of a pair of strong-backs held in place at the free ends of a plank. Instead it is lifted up and down on a telescopic cylinder that is operated by air admitted through a valve at the bottom. Thus the drill works on an air cushion. This adds at least 24 in. to its range.

Newest among safety devices displayed was the little "self-rescue" gas mask forming part of the exhibit of the Mine Safety Appliances Co. This little mask, which really is not a mask at all but merely a small canister with a tube for the user's mouth and a wire clip to hold his nostrils shut, is designed to give every miner 30 minutes' chance to escape in case he is caught by deadly gases while still able to travel. If the device were adopted as standard equipment at a mine, each man going below would have one hanging at his hip. In case of need he would snatch it from his belt, put the tube at the end of the canister in his mouth, clip his nose shut and be assured of safety from carbon monoxide for a given length of time in case the percentage of the gas was not too high.

In atmospheres contaminated by mine fires it is sure to be effective, for the very presence of fire is assurance that the air contains sufficient oxygen to sustain life. The canister is perforated at the outer end. Air inhaled passes through the usual granular charcoal and soda-lime absorbent and then through a layer of "hopcalite," or mixture of the oxides of manganese, copper, silver and cobalt, which changes the carbon monoxide to the relatively harmless carbon dioxide.

The same exhibit showed various other devices, including Burrell gas masks and also oxygen breathing apparatus. The latter device, despite the introduction of gas masks, has yet to find a real competitor except where there is certainty that the oxygen percentage will not be found at any point dangerously low.

Fusibility of Coal Ash

DATA regarding the softening temperature of coal ash from several hundred coals from the different fields of the country are contained in Bulletin 209, "Fusibility of Ash from Coals of the United States," by W. A. Selvig, assistant analytical chemist, and A. C. Fieldner, supervising chemist, U. S. Bureau of Mines, just issued by the bureau.

Information concerning the fusibility of coal ash has become of appreciable value to the consumer of coal, mainly in connection with the troublesome formation of clinkers resulting from the melting of the ash constituents of the burning coal. The growing interest in such data has led the Bureau of Mines to make a general survey of the "fusing" or "softening" temperature of the ash from coals of the United States. It is hoped that this information, when used together with the large number of coal analyses published by the bureau, will assist the consumer of coal in comparing different fuels and in selecting that best adapted for his purpose.

Coal ash is the incombustible residue remaining after the complete combustion of coal; it is derived from the inorganic mineral constituents of the coal. The ash-forming constituents are: (1) Inherent or intrinsic impurities that are present in an intimate mixture with the coal substance, and are derived either from the original material or from external sources such as sedimentation and precipitation while the coal-forming plant remains accumulated; (2) impurities, formed either during the laying down of the coal bed or subsequently, that occur in the form of partings, veins and nodules of clay, shale, slate, pyrite and calcite; and (3) impurities that become intimately mixed with the coal in the process of mining, such as fragments of roof and floor. Coal ash is composed largely of compounds of silica, alumina, lime and iron, with smaller quantities of magnesia, titanium and alkali compounds.

Utah's Only Coal-Retarding Conveyor Lowers Output Of Spring Canyon Mine, Two Hundred Feet

By Charles M. Schloss
Denver, Colo.

THE retarding conveyor as a means of lowering coal from mine openings on the mountain sides to tipples in the valleys, though common in West Virginia and Kentucky, is unusual in the Rocky Mountain region, despite the fact that many mines are so situated that this would be the simplest solution of the lowering problem.

Utah boasts only one retarding conveyor. In the Spring Canyon field the coal beds outcrop a considerable distance above the railroad tracks. The Carbon Fuel Co. has spanned this distance by a two-strand conveyor 375 ft. in horizontal and 200 ft. in vertical projection. The inclination of the major part is at over 34 deg. with the horizontal. Coal is dumped on the shelf or coal bench by a single-car rotary dump into a hopper, from which it is fed by a reciprocating plate feeder to the retarding conveyor. The conveyor discharges onto the shaker screen.

The construction cost of a conveyor system is about the same as that of a gravity plane, but the conveyor has the better of the argument from that point on. First, the severe service to which mine cars are subjected on the steeply pitching planes may roll up during the year a maintenance charge of nearly $50. Second, the track on an incline can be maintained only with difficulty and at much expense. Third, more cars are required when they are obliged not only to haul coal to the head house but to make the trip down the incline and back again. Lastly, with the plane it is necessary to have a terminal on the shelf and one at the bottom, and this demands a crew at each terminal. With the conveyor and dumping cars on top, the dumping crew only is necessary. This in itself is no inconsiderable saving.

It is interesting to hear the opinion of an engineer prominently identified with the design of plants for the handling and preparation of coal:

"Take the history of the coal industry in West Virginia, where almost every known device has been used to take coal down the sides of the mountains—inclined plane, monitor dumping the coal at the top and lowering it to the bottom and rope retarder. In every modern instance you will find that the two-strand conveyor is being used exclusively; as a rule installations with small tonnages are using other devices, and it will be only a question of time until they change. This has been the history of the industry in the Kentucky district. I have never known a retarding conveyor which had been built right to cause any serious delay, but every so often you hear of a trip getting away on an inclined plane. I was told that one wreck in Utah cost $12,000 besides all the incident delay; mine cars were threaded onto railroad irons like buttons on a string, and they were steel cars at that!"

SCENES AT PLANT OF CARBON FUEL CO., RAINS, UTAH, LOCATED IN SPRING CANYON

(1) Tipple and 136-ft. retarding conveyor, capacity, 200 tons per hour. (2) Dump track with derailed car. When a car will leave the track on a level, as here shown, it can hardly be expected to stay on when on an incline. (3) Another view of tipple and conveyor. Reports and Investigations State Geological Surveys and Mining Bureaus

Coal Reserves in Fayette County, Pa., Contained in Seven Beds

By John F. Reese

FAYETTE COUNTY, Pennsylvania, has seven coal beds that may be considered of economic value at the present time. In order of importance, so far as production is concerned, these are the Pittsburgh, Sewickley, Upper Kittanning, Lower Kittanning, Upper Freeport, Waynesburg and Redstone.

Extensive development of the Pittsburgh bed and its outcrop throughout the county have furnished many measurements of its thickness, making possible an accurate and reliable computation of the quantity available. For some localities no information is at hand as to the size of mined-out areas, and an estimate of probable depletion has been based upon the age of development and the size of surrounding operations in those particular sections or on the difference between original areas and statements of areas unmined.

The outcrop and development of the Sewickley coal bed have given many reliable measurements of its thickness. This bed is considered of value as a shipping coal in eight townships. Many mines have been opened in this bed in recent years, and its economic value as a producer of fuel for industrial purposes is second only to that of the Pittsburgh coal.

A fair amount of data regarding the thickness of the Upper Kittanning bed has been gathered from the mines and outcrop along the Youghiogheny River in the Connellsville-Indian Creek region. It has been considered as being of economic value and its contents calculated only in Stewart and Henry Clay townships. Future development and prospecting, however, may show that it is minable in other localities west of Chestnut Ridge.

Development and prospecting of the Lower Kittanning coal in the Connellsville-Indian Creek region have furnished a fair number of measurements of its thickness. It has been computed as of economic value in four townships, namely, Bullskin, Springfield, Stewart and Henry Clay, but future prospecting may show that it is minable in other townships.

The Upper Freeport bed contains the greatest reserve in the county. Its extensive outcrop along Chestnut and Laurel ridges gives numerous opportunities for measurements, making fairly reliable computation of quantity possible. It is assumed that the continuity of this bed is unbroken from the west slope of Chestnut Ridge to the Monongahela River. Core drillholes along the river prove the existence in that region. The tonnage computations are based on many measurements along the outcrop and on an assumed thickness of 42 in. under the townships bordering the river.

A fairly reliable estimate of the quantity of Waynesburg coal available is made possible by the number of measurements along the extensive outcrop of this bed. Because of its accessibility the Waynesburg coal is mined at many places throughout the county for local use. This bed is badly broken by partings, but where the thickness is fairly uniform, there are several mines that are shipping this coal for industrial purposes. Because of the character of the bed, however, it will not become a great producer of shipping coal and will be of less economic value than any of the beds whose quantity has been computed.

Outcrop and shaft sections of the Redstone bed give a fair idea of the extent and thickness of this coal. It is not mined for shipment but is used for domestic purposes in several localities.

Other coal beds than these are mined for local use, but as they are not important and little is known of their extent and thickness, they have not been included in the computation of the reserves.

The result of computing the coal reserves in Fayette County based on the latest maps, engineering data, and methods is shown in the accompanying table.

COAL RESERVES IN FAYETTE COUNTY *

(In Net Tons)

Bed	Original Deposit	Mined Out	Recoverable
Pittsburgh	2,087,772,000	878,030,000	919,300,000
Sewickley	194,175,000	10,132,000	123,600,000
Freeport	2,088,153,000	1,650,000	1,029,000,000
Redstone	151,380,000		75,700,000
Waynesburg	316,854,000	3,216,000	199,800,000
Upper Kittanning	89,280,000	2,016,000	59,000,000
Lower Kittanning	302,120,000	4,500,000	198,000,000
Total	5,229,734,000	899,544,000	2,604,400,000

*The total area of Fayette County is 824.0 square miles.

Detailed tables of the coal reserves in each township have been prepared and will appear in printed form in a report now being written on the bituminous-coal fields of the State of Pennsylvania. They can be consulted in the office of the Topographic and Geological Survey, or figures for a single township will be sent on request.

Investigation of the occurrence and distribution of the forms of sulphur in coal has been continued during the recently ended fiscal year at Urbana, Ill., by the U. S. Bureau of Mines, in co-operation with the Illinois Geological Survey and the University of Illinois under two general heads: (1) The distribution of the forms of sulphur in the coal bed, and (2) sulphur forms in coal. Both are closely co-ordinated with coal washing. The steadily decreasing reserves of low sulphur-coal in certain sections renders it essential to have information on the occurrence and distribution of the forms of sulphur present in coals higher in sulphur, so that intelligent efforts may be directed toward reduction of sulphur and then utilization. The distribution of the forms of sulphur in coal beds was investigated at two mines in southern Illinois. A similar though less intensive investigation was made at a mine operating in the Pratt seam in Alabama. Since this work was done, one mine has materially reduced the sulphur content of both raw and washed coal by developing their lower sulphur areas. The work on the sulphur forms occurring in coal is being conducted with the object of correlating the occurrence of sulphur forms with the washability of various coals with respect to sulphur reduction. During the year all the raw coal upon which washing tests were made and the washed products have been examined for the various forms of sulphur. It has been found that the organic sulphur content of a raw coal plus its content of finely disseminated pyrite sulphur fixes a limit below which no reduction in sulphur can be effected by ordinary coal-washing methods.

Problems that develop in the mechanical preparation of coal in the Central and Eastern coal fields are being investigated at the Central experiment station of the U. S. Bureau of Mines at Urbana, Ill., in co-operation with the University of Illinois and the Illinois Geological Survey. Work on coal-cleaning methods is being continued, as the problem of cleaning coal is receiving more attention in the bituminous-coal mining industry. A study has been made of the methods of examining a coal as it exists in the raw state, in order to determine the practicability of improving it by coal-cleaning processes.

Problems of Operating Men

Edited by James T. Beard

Finding the Way to Industrial Peace

Solving the Labor Situation by the Golden Rule —Spirit of Goodwill and Co-operation Needed —Mutual Dependence of Capital and Labor

WITH much interest I read the excellent article of M. J. Facemeyer, entitled "Peace and Harmony," *Coal Age*, Sept. 28, p. 499. I was much impressed with the truth of his opening statement, which reads as follows: "Just now, nothing is of more interest and importance than suggestions looking to the promotion of peace and harmony in the general rank and file of the coal-mining industry."

Reading this article recalls the statement made by Roger W. Babson, in his report on the social, economic and political problems that confront the American people. As quoted in *Coal Age*, Vol. 17, p. 364, Mr. Babson says, "The need of the hour is more religion. The solving of the labor situation is wholly a question of religion."

As I understand it, the report of Mr. Babson seems to show that the recognition of God, in the financial affairs of men, is the only basis for industrial peace and lasting prosperity. It is, I believe, the only hope of a permanent settlement of the present industrial disturbances.

Our Greatest Need Today

We all realize, today, that the suggestions of this student of social and economic conditions have not been put into practice by either capital or labor. Controversies between these two factors of industry still continue, paralyzing business and bringing ruin to more and more innocent and helpless people, as the days go by.

To the thoughtful man, the greatest need of our country, today, is not the heralded mountain wave of prosperity; but, instead, a gentle wave of goodwill and co-operation in the hearts and minds of men, whether they labor with their hands or with their capital and brains.

Too often the question of right and wrong has not been mentioned as a factor in the adjustment of industrial differences. Instead, higher wages and larger profits have confronted each other in a hopeless struggle for ascendency. It is victory or defeat, for one side or the other, regardless of the cost. How different would be the aspect, if greed, hatred and selfish ambition was to give place to the practice of the Golden Rule, which is the only solution to these problems.

No wisdom is required to perceive that our present industrial controversies can never be permanently adjusted if capital and labor continue to seek to humiliate each other. Capital can never overcome labor by force and reduce it to starvation wages. On the other hand, labor cannot force capital to concede unjust demands that would destroy the country's business.

Prevailing Disregard for Law

Prosperity can only be permanent when it smiles alike on both capital and labor. It is not new laws or legislation that is needed; but the spirit of goodwill and co-operation must dominate. Never, in the history of our country, has there been so little regard for the supremacy of the law and its enforcement as there is today.

There is no need to rehearse those wanton acts of murder and destruction at which the world has so recently stood aghast. What is most discouraging is the evident approval given to such dastardly doings by local organizations and communities.

There is no mistaking the fact that dangerous un-American principles are present with us. Certain elements among our laboring classes have spread their poisonous doctrines, to such an extent that the fires of hatred and selfishness now smolder in the hearts of their helpless victims. It stands in hand for the better element of all classes of workmen and citizens alike, to be loyal in the preservation of those American principles of justice and individual rights, or these will soon be destroyed forever.

Capital and Labor Problems

The problems that confront industry, today, have grown to proportions that require level-headed judgment in the recognition of individual rights. All will agree that labor should receive something more than a living wage, in return for efficient service. Labor is entitled to a profit on its toil, as truly as invested capital demands a reasonable gain for its use. Labor must provide against the proverbial "rainy day," and capital must safeguard its interests against the fluctuations of trade.

When one considers the mutual dependency of capital and labor, the one on the other, it is hard to understand why labor should want to embarrass capital, or capital desire to humiliate labor. So akin are their interests that one is as much bound to promote and protect the welfare of the other, as though it was their own.

Both capital and labor are important in their respective spheres; both are indispensable factors in the industrial enterprises of the country. In my opinion, the time has fully come when the old order of things will be exchanged for the new. A more humane and Christian spirit must assert itself and prevail, while the old weapons of boycott, strike and labor warfare are forever laid aside.

In closing, let me say there is only one remedy that can be applied with any assurance of permanent success. It will be found in a return to the teaching of the Man of Nazareth, on the part of both labor and capital. There will then be no disposition to do anything but right in the treatment of another and the problem will be solved.

Dayton, Tenn. JOHN ROSE

Keeping the Mine Safe

Humidifying mine air with steam— Broadcasting salt in the airways— Removing all accumulations of dust —Spraying system not effective— Preventive measures more reliable.

READING the article of F. C. Cernet, *Coal Age*, Aug. 8, p. 169, dealing with the question of humidifying air currents by steam, leads me to offer a few comments on this and other methods of keeping the mine safe.

In regard to this method of humidifying mine air, I naturally assumed that the main haulage roads are the return airways, although it is not so stated in the article. In mines where the main haulage roads are made the intake airways, the use of steam would be objectionable, as it would seriously inconvenience the drivers and men working on the bottom.

Humidifying the Mine by Steam

Assuming an intake airway, however, I can heartily recommend the use of steam for humidifying the air current. Whether a straight line of pipe is installed for that purpose or a radiator system is employed is immaterial, as either method can be made alike effective.

In the first place, I would suggest a general clean-up of all roads and aircourses, removing any accumulation of dust and hauling it out of the mine. If a steam line is used the pipes should be tapped at short intervals, by drilling small holes to permit the escape of the

[illegible] salt on the mine.

Sprinkling Salt on the Mine

Let me suggest, here, that the broadcasting of salt on the roads, traveling-ways and aircourses throughout the mine is a good plan. By absorbing moisture from the air, the salt keeps everything in a damp condition and prevents the fine dust from rising and floating in the air.

At times, I have seen the mine drainage arranged to collect the water in a sump where a high-pressure pump was installed to force the water through a pipe system by means of which it is sprayed on the roads and traveling-ways. Three or four cross-pipes would sometimes be arranged across the intake airways and drilled with a line of small holes, thereby forming a spray for humidifying the intake air.

In my opinion, no spraying system is thoroughly effective. I believe that watering the dust does not increase the safety of the mine, or render the dust less explosive. If the mine is to be made safe, other means than watering and spraying the passageways must be evolved.

Necessity of Maintaining Good Circulation of Air

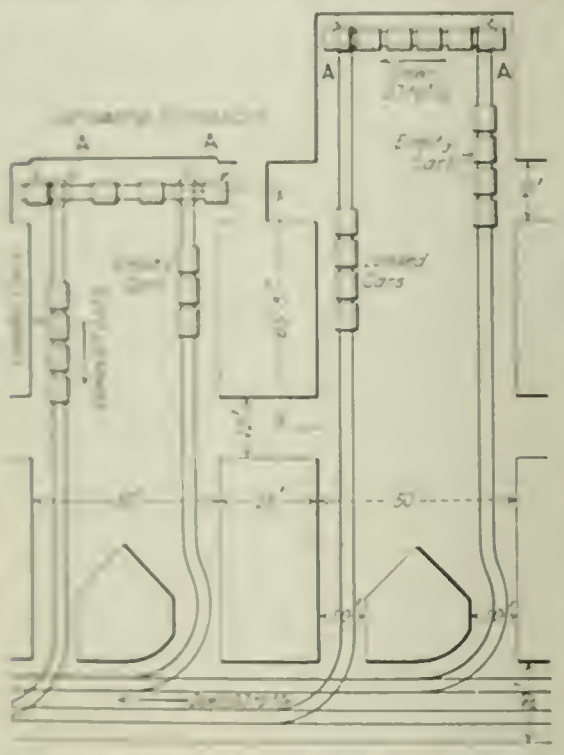
One of the chief factors, in mine safety, is maintaining a good circulation of air throughout the workings. To do this, it will often be necessary to repair doors, stoppings and air bridges, to prevent air leaks, and erect brattices to cause the air to sweep the face of the coal.

Blasting the coal is next in importance. Where the coal is hard and solid shooting is practiced, nothing but permissible explosives should be used. Every effort should be made to reduce the breakage of coal by avoiding excessive charges of powder. It is also important to use cars that will not require to be loaded above the sides.

The loading of cars with topping is a bad practice. When so loaded, much of the coal falls off the car in transit; and is ground into fine dust by the car wheels and the travel of men going to and from their work. These and many other items that might be mentioned play an important part in making the mine safe. Oscar H. Jones.

Wilder, Tenn.

Continuous Car Supply in Rooms



Expediting the loading of cars at the face—Use of turntables suggested—Practice in European mines—Sending details of arrangement of tracks and cars.

IN THE issue of *Coal Age*, Aug. 24, I wrote two suggestions for expediting the loading of coal at the working face in mines. The first of these occurs in the interesting article of E. N. Zern, page 241, entitled "Excelling the Turntable in Mechanical Coal Loading." The second is found in the letter of Charles H. Bohlen, page 256, who suggests extending the room track along the face of a room, so as to permit several cars to be loaded at one time.

Referring to the article of Professor Zern, it seems to me that the suggested use of turntables in coal mines deserves more than passing attention. Besides the particular case referred to in the article mentioned, there are many places in the average coal mine, where turntables could be used to advantage.

While I am unable to refer to a single case where turntables are used in present-day coal mining, it can be said they are a standard article of equipment in the metallic mines, on the European continent. As far back as the 80's, I remember seeing turntables in use in the phosphate mines of Belgium and in the Somme department in France.

In this connection, allow me to illustrate, by means of the accompanying

SHOWING TRACK ARRANGEMENT IN ROOMS

sketch, how turntables were used in the rooms of one phosphate mine that was famous about thirty-five years ago, in the region of Mons, in Belgium. The deposit mined there was a bed of phosphatic chalk, which was a mixture of chalk with a certain amount of fine dust and pure phosphate of calcium.

The phosphate was recovered from the finely crushed chalk by washing. The ore was first mined by hand and then shot down with either dynamite or black powder, depending on the condition of the strata. The bed varied from 14 to 18 ft. in thickness, and the cover did not exceed 75 or 80 ft.

Double-Track Room with Cross-Track and Turntables

As shown in the figure, double-track rooms were driven 15 m., or nearly 50 ft., wide. The two tracks were laid, one along each rib of the room, and a cross-track and pair of turntables served to connect them, at the face.

To show how this arrangement permitted a continuous supply of cars at the face, let me say that a driver would send in eight or ten empties on the righthand track, as close to the turntable as possible. Then, when ready to load, the miners would place five or six cars on the cross-track, using the turntable to make the transfer. These cars would all be loaded at one time and dropped out on the lefthand track, by means of the turntable at that end of the face, and hauled away by the driver.

Standard Rail Lengths Conform to Distance Between Crosscuts

The steel rails used were 5 m. (16 ft. 5 in.) long; but there were kept on hand, in each room, four half-rail lengths, which enabled the miners to set the face track forward whenever the face had been advanced that distance. The crosscuts were dug at intervals of 4-rail lengths. Whenever the face track was set where a crosscut had to be driven, rails were laid opposite to the turntable rails, on the rib side. In each room two opposite crosscuts were driven at the same time, half-way through the pillar, the other half being driven from the room adjoining.

Although the cars used were large self-dumping affairs, similar to what were in use by railroad and other contractors in the region; and, though they had a capacity of 2 cu.m., or nearly 71 cu.ft. level full, there was no difficulty in handling them over the turntables and across the faces.

My purpose in describing these arrangements thus minutely, is to ask why such an arrangement could not be used in coal mining to advantage. The plan should appeal to any one as affording a continuous car supply at the face and expediting the loading of the coal.

New York City. F. C. Cornet.

Flow of Water in Pipes Under Equal Heads

Attempt to simplify solution of flow of water in pipes under equal heads—Readers can judge for themselves.

HAVING been for several years somewhat of a dabbler in hydraulics, I was interested in the question of an Ohio student, appearing in *Coal Age*, Oct. 5, p. 551. While the answer given to the problem is entirely correct, it seems to me that the inquirer is left in the position of simply accepting it without knowing the reason.

The inquirer refers to a dispute regarding the number of 3-in. pipes required to carry away the same quantity of water as a single 12-in. pipe, all the pipes being under equal heads. Since the sectional area of the 12-in. pipe is equal to the sum of the areas of sixteen 3-in. pipes, it was claimed that the quantity of the flow would be the same in each case.

In replying to this question, the editor has shown that this is true only for an equal velocity. He states, "A more practical view of the question, however, is to consider the flow of water in these pipes as under a constant head or pressure," which is true.

Then, he adds, "owing to the frictional resistance in the pipes, a constant head will not produce the same velocity or quantity in pipes of different diameters," and goes on to explain by reference to the well-known formula for the unit pressure producing a flow of any fluid in a conduit.

Would it not have been better to have explained the situation somewhat as follows: Experiment has shown that the resistance of the flow of water in pipes is, approximately, proportional to the square of the velocity of the flow and also to the area of wetted surface of the pipe. The total pressure applied to overcome this resistance is equal to the unit pressure (lb. per sq.in.), multiplied by the sectional area of the pipe, expressed in square inches.

Now, the unit pressure corresponds to the head, which is the same for all the pipes. Again, the sectional area of a single 12-in. pipe being equal to the sum of the areas of sixteen 3-in. pipes, the resistance to the flow is the same in each case; and we can write $pa = v^2 s$, where p = unit pressure; a = total sectional area, in each case; v = velocity of flow; s = total wetted surface in the pipes, in each case.

Then, assuming equal lengths for all the pipes, and expressing the values of a and s in terms of the diameter d, remembering that $v = q/a$, we have

$$pd^2 \text{ varies as } \frac{q^2}{d^4} \times d$$

But, the unit pressure p being constant, we have by transposition q^2 varies as d^5; and, finally, q varies as $\sqrt{d^5}$. In other words the diameter of the 12-in. pipe being four times that of a 3-in. pipe, the flow of water in the former, under the same head, will be $\sqrt{4^5} = \sqrt{1,024} = 32$ times that in the latter. Therefore thirty-two 3-in. pipes will be required to give the same flow as one 12-in. pipe, under the same head.

Charleston, W. Va. T. L. F.

[Another letter of a similar nature to the foregoing was received from Thomas Anderson, Barnesboro, Pa. Neither of these gentlemen appear to have turned over the leaf and read the conclusion of the reply to this inquiry on page 552, as their letters contain nothing different from what is there stated.—Editor.]

Inquiries Of General Interest

Interchange of State Certificates

Certificates of Competency Granted by Examining Board in One State Honored by Similar Board in Another State —The Practice of Interstate Certificates Growing Rapidly

AS A subscriber to *Coal Age*, kindly permit me to ask for a little information regarding a certificate of competency granted by one state, being accepted by the examining board in another state. For example, I hold a first-class certificate granted me by the state examining board, in Alabama. For certain reasons, I now desire to remove to Illinois and have been wondering whether my certificate would be of any use to me in that state. If not, what are the requirements, in Illinois, in order that a man can take the examination for a certificate authorizing him to act as mine manager (foreman)? Is a first-class certificate granted in Alabama equivalent to a mine manager's certificate in Illinois? Any information on this subject will be greatly appreciated. R. FORTUNA.

Nauvoo, Ala.

This is the old question of interstate certificates, which has been so frequently discussed in mining papers and at meetings of mining men. While the practice of accepting certificates granted candidates in another state is by no means universal, the custom has been growing during the past few years; and many state examining boards now are willing to accept such a certificate when presented by a candidate coming from another state, provided the examinations are of the same grade and importance.

The question of accepting such certificates on the part of the Illinois Examining Board was recently put up to the director of the Department of Mines and Minerals, Robert M. Medill, Springfield, Ill. In his reply, Mr. Medill states that since his appointment as Director of the Department of Mines and Minerals he has taken the position that the department should honor a certificate from another state where the candidate was required to pass an examination similar to that given by the department in Illinois. Director Medill adds that such a candidate, however, would be subjected to a slight oral examination, in order to determine his fitness for the position desired and confirm his acceptability by the Illinois Mining Board.

It is needless to say that the practice of interstate certificates, properly safeguarded by subjecting a candidate to a sufficient oral examination to confirm the certificate he presents, is in accord with what has been advocated in *Coal Age*, for a number of years.

The subject of interstate certificates of competency was discussed at a meeting of the Mine Inspectors Institute of America several years ago. The concensus of opinion at that meeting was in favor of such certificates being given due consideration by state examining boards when presented by candidates applying for examination.

To what extent the certificate can be accepted will, of course, depend on the respective standards of examination in the two states, and this can only be determined by the examining board in considering a candidate's application.

Size of Pulley Required

Ratio of diameters of pulleys on motor and fan same as the inverse ratio of their respective speeds.

IN THE operation of a booster fan having a 24-in. drive wheel, what size of pulley will be required on the shaft of a motor running at a speed of 1,500 r.p.m., in order to drive the fan at 600 r.p.m.? MINE FOREMAN.

———, Ky.

Assuming there is no slippage of the belt connecting the fan with the motor, the ratio of the diameter of the pulley on the motor shaft, to the diameter of the drive wheel on the fan shaft, must be equal to the ratio of the required speed of the fan to that of the motor.

In other words, the diameter ratio is equal to the inverse speed ratio. Then, calling the required diameter of the pulley on the motor shaft x, we have

$$\frac{x}{24} = \frac{600}{1,500} = \frac{2}{5}$$

$$x = 2/5 \times 24 = 9.6 \text{ in.}$$

Estimating Available Tonnage

Approximate rule for computing available tonnage of coal underlying a given tract—Allowance per foot-acre varies with quality of coal—For inclined seams divide estimated tonnage by cosine of angle of inclination.

A DISCUSSION has recently arisen among some coal men, in this locality, concerning the available tonnage underlying a 1,400-acre tract, the seam being flat and averaging 8½ ft. in thickness. Allowing 1,400 tons per acre, the estimated tonnage of coal, in this seam, would be 156,800,000 tons. This amount being disputed by some, it was decided to ask *Coal Age* if it is correct. ENGINEER.

Meeker, Colo.

An approximate rule of thumb that has been often used in computing the weight of coal underlying an acre of land, assuming a flat seam of bituminous coal of average quality, is to base the estimate on 1,000 tons per foot-acre.

Later, however, when the extraction of coal became more complete, this rule was discarded and the estimate based on 100 tons per in. per acre, or 1,200 tons per foot-acre. Both of these rules had reference to bituminous coal in a flat seam. Anthracite will average 1

When a seam has any considerable inclination, this estimated tonnage must be divided by the cosine of the angle of inclination. It is understood that the application of this rule for computing available tonnage is only approximate and will vary with the quality of the coal and the percentage of extraction. The rule given allows about 80 per cent of extraction for average coal.

Examination Questions Answered

Miscellaneous Examination Questions

(*Answered by Request*)

QUESTION—*What is the best method of humidifying a dusty mine?*

ANSWER—The most practicable method of humidifying the air current in a mine is to introduce steam into the air current, on the intake airway, after heating the air by causing it to pass over a system of radiators or steam coils. The waste steam of this heating system is then permitted to escape into the warm air current, through perforations in the pipes. The escaping steam should be made to impinge on baffle plates or canvas curtains, for its better distribution.

QUESTION—*Find the mine resistance when the water gage reads 2.5 in., in an airway 6 x 10 ft. in cross-section.*

ANSWER—A water-gage reading of 2.5 in. indicates a pressure of $2.5 \times 5.2 = 13$ lb. per sq.ft. The sectional area of this airway is $6 \times 10 = 60$ sq.ft.; and the mine resistance is, therefore, $60 \times 13 = 780$ lb.

QUESTION—*What pressure and water gage will be required to pass 60,000 cu.ft. of air per min., through an airway 8 x 10 ft., 4,000 ft. long?*

ANSWER—The perimeter of this airway is $2(8+10) = 36$ ft.; and the rubbing surface is, therefore, $36 \times 4{,}000 = 144{,}000$ sq.ft. The sectional area of the airway is $8 \times 10 = 80$ sq.ft. The pressure required to circulate 60,000 cu.ft. per min. through this airway is, therefore,

$$p = \frac{0.00000002 \times 144{,}000 \times 60{,}000^2}{80 \times 80 \times 80} = 20.25 \text{ lb. per sq.ft.}$$

The corresponding water gage is, then, $20.25 \div 5.2 = 3.9$ in., nearly.

QUESTION—*What will be the diameter of an upcast shaft necessary to pass 200,000 cu.ft. of air per minute with a velocity of 500 ft.?*

ANSWER—Dividing the air volume, in cubic feet per minute, by the velocity, in feet per minute, gives the required sectional area of the shaft; thus $200{,}000 \div 500 = 400$ sq.ft. The required diameter of the shaft is therefore $d = \sqrt{400 \div 0.7854} = 22.56$ ft.

QUESTION—*A certain mine has two shafts, each 500 ft. deep. The temperature of the downcast is 50 deg. F. and that of the upcast 150 deg. F.; what is the motive column?*

ANSWER—The motive column can be estimated in terms of either the downcast or the upcast air. The downcast air being the heavier will give a shorter motive column than the upcast air. The calculation is as follows:

$$\text{Down cast air, } M = \frac{(T - t)\,D}{460 + T} = \frac{(150 - 50)\,500}{460 + 150} = 82 \text{ ft., nearly}$$

$$\text{Up cast air, } M = \frac{(T - t)\,D}{460 + t} = \frac{(150 - 50)\,500}{460 + 50} = 98 \text{ ft.}$$

QUESTION—*How is it possible to divide the air proportionately between two or more splits?*

ANSWER—Regulators must be placed in those splits that are passing more than their desired proportion of the air. The opening in each regulator must then be adjusted to give the desired results.

QUESTION—*What is the law regarding the method of approaching abandoned mines?*

ANSWER—The Indiana Mining Laws (Chap. 258, Sec. 14) require that places being driven toward an abandoned mine shall not exceed eight feet in width; and a borehole shall be kept in the center of each place and not less than three yards in advance of the face. Also, sufficient flank boreholes must be kept on each side of the place so driven.

QUESTION—*What are the causes of mine fires? How would you proceed in case of a fire in a mine of which you had charge? Give full details.*

ANSWER—Mine fires may result from the careless use of open lights, in proximity to combustible material; the ignition of a gas feeder by the flame of a shot, and the fact not discovered until the coal has been ignited and the fire has spread; spontaneous combustion of fine coal and slack, buried in the waste in abandoned places; the ignition of combustible matter by the sparking of wires, short-circuiting of the current, etc.; the ignition of gas or dust by similar causes; explosion of gas, dust or powder, due to careless handling or disregard of safety precautions and rules.

In case of fire occurring in a mine, the men working therein should be promptly notified and withdrawn by the safest route possible. Treatment of the fire will depend wholly on its location and the headway it has gained. Immediate steps must be taken to get water to the fire, and to prevent the gases and smoke from entering the workings, as far as this may be possible, by short-circuiting the current at some accessible point inby of the fire. If progress is slow in gaining control of the situation it may become necessary to seal off the fire by building air-tight stoppings. The advisability of this proceeding can only be determined on the ground. Only as a last resort should recourse be had to the flooding of the mine, in order to extinguish the fire.

Critics of British Coal Strike Settlement Charge Juggling of Production Costs

By C. H. S. Tupholme
London, England

Some critics of the British coal strike settlement of June, 1921, contend that the proportion of profits to wages is unduly high and that the ratio will have to be adjusted in favor of the men; others profess to believe that the scheme lends itself to figure "juggling" by the owners. Vague charges have from time to time been brought against the colliery companies in respect of "rigging" the costs of production. It has been alleged that "other costs"—i. e., items other than wages, stores and material—have been piled up in order that the employers may benefit at the expense of the men. It is true that none of the responsible leaders of the workmen has made such an accusation, but there is some evidence to show that others have not scrupled to sow the seeds of suspicion among the men with the object of stirring up discontent and arousing hostility against the pact of last year.

In the circumstances it is necessary to emphasize the fact that the independent chairman of the National Board has laid down categorically every item which is to be treated as a working cost other than wages, while he has further carefully laid down the basis upon which items are to be calculated. In addition to timber and stores, the following have been admitted as "other costs": (1) Depreciation and renewals; (2) freehold coal royalties; (3) surface damage and restoration of service at end of lease; (4) workmen's compensation payments and insurances; (5) national health and unemployment insurance (owners' proportion of contributions); (6) remuneration of owner managers; (7) fire brigade, rescue, and aid services, etc.; (8) welfare levy payable under the Mining Industry Act, 1920; (9) allowance to make up subsistence wages; (10) local rates; (11) remuneration of directors, mine manager, general manager, and secretary; (12) remuneration of clerical and administrative staff other than No. 11; (13) pensions; (14) general expenses; (15) coal and power purchased and consumed; (16) repairs and renewals of colliery wagons; (17) schedule A assessment of workers' houses and occupiers' rates borne by owners and not recoverable; (18) wagon charges; (19) other debits.

The accountants acting in the men's interests have access to all accounts bearing on these costs, and they are, therefore, in a position to check every item and satisfy themselves that everything is as it should be. The men themselves are now able to obtain much fuller and more detailed information that was available when the argument was first put into operation, and so they are afforded ample safeguard against any undue inflation of costs.

Overhead Expenses in American Coal Mines Considered in Relation to "Rigging"

By W. B. Reed
Washington, D. C.

Mr. Tupholme's article on the possibility of "rigging" or padding the cost of coal in order to increase the actual profit to the operator or owner under the British system of a division of profits between the owners and the miners gives us an opportunity to compare "overhead expenses," as we designate what the English accountants term "Other Costs."

A comparison of the items of overhead and other operating expenses set out by the British National Board with the generally accepted items in this class as recommended by the cost accounting committee of the National Coal Association shows considerable similarity of treatment. There are several items embraced in the British plan which do not appear in the accounting practice here. For instance, "surface damage and restoration of surface" does not appear specifically as an item of cost in our cost sheets, although such items are properly chargeable to operation. The American practice is to set up a fund for mining hazards and to charge the cost of such contingencies to this account when they occur. Our accounting practice does not recognize any specific account of national health and unemployment insurance, our nearest approach being group life insurance as carried by some concerns. We have no legal liability such as is termed "welfare levy," the welfare work, where it obtains, being the voluntary contribution of the operator, while in Great Britain it is apparently obligatory on the owner to finance to an extent such activities. Neither do we have "allowance to make up subsistence wages." The item of pensions is one which we would ordinarily consider as a charge against income rather than a direct item of cost.

It may be profitable, perhaps, to examine our own generally accepted method of cost determination to see if it is open to the charge of "rigging" or padding of the items indicted in the English mind. The accounts which lend themselves most readily to the abuse mentioned are the depreciation account, the accounts carrying officers' salaries and the supply accounts. Of these, the depreciation account is the most difficult to police, for when based on a rate per cent it is a matter of good judgment as to the rate to be used. Conditions in each separate mine, the policy of the management as to maintenance and replacements, and the life of the coal all have to be taken into consideration. When based on exhaustion, or, in other words, on the depletion plan, a more even measure of the consumption of capital by depreciation may at times be obtained. But the Internal Revenue Bureau has held that depreciation may be forestalled and "sound value" maintained by a policy of the management in keeping machinery and equipment up to its productive capacity.

Undue Increase in Officers' Salaries Unlikely

With respect to officers' salaries and expenses, there is little likelihood of their being increased unduly except in the case of closely held corporations, in which the disbursement takes the form of a dividend. The Internal Revenue Bureau is continually on the lookout for this method of distributing earnings and it cannot long pass undetected. The same "policeman" is always on the lookout for the former item of depreciation and for the abuse of the practice of charging of additions and betterments to the supply account.

In the last-named item the line of separation in the past few years has been quite clearly drawn. If the item purchased or installed will materially increase production or materially and permanently decrease production cost, it should be capitalized; otherwise after the development stage is passed there should be no capital additions, but everything of this nature treated as operating cost.

The studies made by the engineers' committee of the United States Fuel Administration and by the Federal Trade Commission with respect to coal costs are interesting as showing the small difference between "reported costs" and "adjusted costs" during the period in which the coal industry reported to these bodies. These adjusted costs were used by the Fuel Administration engineers in their cost studies. This committee frequently found it necessary to add to the item of salaries of officers and management as well as to deduct from others, that a representative showing might be made. The engineers committee reported that in their first study on a production of nearly 72,000,000 tons of coal the average cost was "adjusted" exactly 1c, and that they *increased* the cost by the adjustment.

The Federal Trade Commission in its report on cost of production of Pennsylvania bituminous coal shows a revision downward from all causes of about 7c. per ton for the year 1918. The report says, "The Commission is able to point out that the costs of from 90 to 95 per cent of the tonnage reported from a given field were as a rule accepted as substantially correct. Certain revisions were found necessary, however, and while generally they operated to reduce costs, in some instances they increased them. Most of the revisions occur under 'general expense,' where most of the inflations were found to have taken place."

Preliminary Statistics of Production of Coal in 1921

Ohio

County	Total Quantity (Net Tons)	Total Value	Average Value per Ton	Number of Employees — Underground — Miners, Loaders, etc.	Underground — All Others	Surface	Total	Average Number of Days Worked

Union Mines in Washington State Resume: Open-Shop Operations Unaffected

"With the union properties again operating the state's normal flow of coal will doubtless soon be available, and until further interruptions occur, any danger of a shortage to either industry or household is past. The danger rather is that because of the most severe competition of low-priced fuel oil and of cheaply mined foreign coal, the commercial mines may have difficulty in securing sufficient market to keep steadily working.

"It is fair to assume, however, that because of their more dependable basis of operation and because of having been in a position to supply and keep a continuous hold on their markets during the recent crisis, the western Washington mines will be in the most favorable position to retain those markets.

"The Pacific Coast Coal Co. takes this opportunity of again stating that its policies have not been in any way affected by the recent union settlement, nor will they be by any future developments."

Valuation of Anthracite Lands for Taxation Soars; Schuylkill County Makes 650 Per Cent Raise

Systematic efforts to burden the anthracite industry with taxation amounting to a levy on capital are creating an issue of the highest importance to all coal-land owners in Pennsylvania and to all consumers of coal. With due regard to all the complications arising from the recent strike and to all the possibilities contained in the investigation by President Harding's commission, this matter of taxation is in some phases the most important question before the coal-producing and coal-consuming public.

The hotbed of the present tax movement is in Schuylkill and Northumberland counties, comprising the southern and western middle anthracite fields. The Schuylkill County commissioners, in making their triennial assessment this year, have marked up county valuation for all tax purposes from $99,935,909 in 1921 to $497,510,263 for 1922.

The great bulk of this increase has been placed upon anthracite lands, which were valued at $55,907,496 in 1921 but which are placed at approximately $422,000,000 for 1922, the increase being more than 650 per cent. As the tax rate for 1922 has been placed at 2.75 mills for county purposes, the total tax yield on a basis of 100 per cent collection would be $1,368,153 on the 1922 valuation, and of this $1,160,500 would be taken from coal-land owners.

As matters stood under the 1921 assessment, coal-land owners paid about 65 per cent of the total county tax collected. Under the proposed valuations coal-land owners would have to pay about 89 per cent, allowing for exonerations and non-payment by individuals.

Up to this point only county taxes have been considered. There remain school taxes, road taxes in townships and the ordinary municipal taxes in the boroughs and the City of Pottsville. The new schedule of valuations means that a burden similar to the county taxes will be placed on coal-land owners by school, township, borough and city authorities.

Last year the county tax in Schuylkill was, roughly estimated, about one-quarter of the taxes collected by all agencies, other than state and federal. If this proportion should be carried through on the 1922 valuations it is probable that coal-land owners would be billed for about $5,250,000 county, school and municipal taxes. This is equivalent to about 35c. or 40c. per ton of anthracite production in that county. Applied to the production of domestic sizes only it means a local tax burden of between 60c. and 70c. per ton.

Owners Petition for Setting Aside of Valuations

Naturally, coal-land owners intend to appeal. They have already attacked the action of the commissioners through an equity proceeding brought by the Pardee interests and joined by numerous other coal-land owners as intervenors. The contention was that the commissioners were not proceeding according to law, and the petition was for setting aside their valuations, with instructions from the court to do the work in accordance with the statutes. This bill was dismissed by the Schuylkill County Court, but an appeal has been taken to the Pennsylvania Supreme Court and will be heard early in the January term.

This equity proceeding is no bar to an appeal in law from the commissioners to the Schuylkill County Court on the ground that the valuations are inequitable, excessive or unjust. This appeal in law must be taken by Dec. 6. As the coal-land owners will neglect no effort to obtain relief, this proceeding in law undoubtedly will be well under way before a final decision in the equity case is given by the Supreme Court.

From a political standpoint the commissioners have proceeded admirably, for they have forestalled objections from the selfish or unthinking part of the public. Last year the county tax rate was 9 mills. This year it is to be 2.75 mills. In effect, property owners outside of coal-land owners have been given to understand: "This soaking of the coal companies is a good thing for you. It is true we have increased your valuations a little, but we have cut your rate, so that you will pay less money in taxes on the 1922 valuation than you did in 1921."

The result is an almost entire absence of public opinion against what is in its essence a grave assault against the fundamental industry of the region. The expression "soaking the coal companies" is literally exact, for the county, whose real-estate tax revenue last year (100-per cent basis, 9 mill rate, $99,935,909 total valuation) was $899,423, this year proposes to collect, on the 100-per cent basis, $1,368,153.

The following list embraces most of the important towns and townships within the Schuylkill coal measures, and shows how the County Commissioners have marked up valuations:

District	1921 Valuation	1922 Valuation
Ashland Borough	$2,014,391	$11,106,000
Coaldale Borough	1,993,556	11,581,000
Girardville Borough	896,675	4,031,000
Mahanoy City Borough	2,436,000	7,309,000
Minersville Borough	1,444,767	4,874,000
Shenandoah Borough	4,355,490	12,339,000
Tamaqua Borough	3,122,150	11,592,000
Pottsville City	8,672,187	22,926,000
Foster Township	1,871,993	6,181,000
Hegins Township	3,153,893	12,998,000
Kline Township	945,008	2,541,000
Mahanoy Township	6,084,157	30,900,000
West Mahanoy Township	4,679,205	13,721,000
New Castle Township	1,755,571	7,566,000
Norwegian Township	2,132,458	23,109,000
East Norwegian Township	979,970	9,792,000
Porter Township	3,170,637	17,379,000
Rahn Township	1,742,268	13,652,000
Reilly Township	3,317,321	30,121,000
Schuylkill Township	2,965,728	28,556,000
Tremont Township	3,863,813	29,454,000
Union Township	1,446,764	2,511,000
Walker Township	835,226	12,064,000

The County Commissioners retained as "expert" engineer a man named William H. Monroe, of Scranton, paying him $25 per diem, with expenses. The contention of the coal-land owners, made in the equity case before the Schuylkill County Court, was that the commissioners did not take the reports of the assessors, who are the only valuation officers known to the law, but set aside the returns and had new ones made out. In general the valuations, they hold, do not meet the plain terms of the Pennsylvania tax law, which requires that the market value, actual or as nearly as may be determined, shall be the valuation for tax purposes.

The contention with respect to the latter point is unquestionably well founded. For example, 241 acres of coal in the Pottsville coal reserve changed hands this year. This is nothing but a mineral right, carrying no surface rights. The character of the geological measures in this tract is such that probably as much as 250 ft. of surface support must be maintained. As a practical mining proposition this means that this particular acreage cannot be utilized until mining adjacent to Pottsville gets down below 250 ft., so that this 241 acres can be reached through workings whose outlet is beyond the city limits. There is no prospect of any such development for 40 or 50 years, and maybe longer.

This property was offered at public sale, two bidders appearing and the whole area being sold for $115,000. The valuation for tax purposes last year averaged $250 per acre. In the face of this bona fide transfer, however, the County Commissioners have this year valued this coal for tax purposes at $4,700 per acre, or almost ten times as much as the actual sale price shown in the deeds recorded within the last few months.

The Lehigh Coal & Navigation Co., which has some holdings in the Pottsville basin, is offering at public sale a tract of 574 acres, partly in Pottsville and partly in the two Norwegian Townships and the boroughs of Mechanicsville and Port Carbon. This is a homogeneous property, being of the same general character throughout and containing the

principal veins of that basin—Buck Mountain, Mammoth and Primrose. But this land is valued at $4,700 an acre in Pottsville, $4,150 in the adjacent borough of Mahanoyville, $3,750 in the borough of Port Carbon and $5,220 in the Tuscarora—a variation of $970 per acre in valuation in a tract of less than one square mile.

Anthracite taxation conditions in Northumberland County bear a strong family resemblance to those in Schuylkill County. William H. Monroe, of Scranton, who was associated with the late Ellsworth Davies in many of his enterprises with respect to coal lands and coal-land valuations, appears in Northumberland County, as in Schuylkill, as the "expert" adviser of the County Commissioners, although the county has a capable mining engineer in H. F. Bickhard, of Shamokin.

The total valuation of coal lands in Northumberland County in 1921 was $26,318,000. This year they were marked up over the neighborhood of $100,000,000, and then the commissioners, on June 12, fixed upon $50,353,541 as the final revised valuation. This final revised valuation has been appealed to the Northumberland County Court, and the case will be heard soon. This increase in valuation is not as excessive as that in Schuylkill County, but the whole transaction carried some unusual features which have attracted wide attention in the hard-coal country.

County Commissioners John Roach and David Hughes, over the negative of Commissioner John W. O'Gara, entered into an arrangement with Monroe and with former Judge Fred E. Moser as special assistants, binding themselves to pay each a retainer of $1,000, a maximum fee of $10,000, and to fix their final pay on the basis of one-tenth of 1 per cent for each man on the total increase over the previous valuations.

Monroe and Moser were hired in March, and the final revised valuation was announced by the County Commissioners three months later. For their services these men stand to get $26,315 each, equivalent to nearly $9,000 a month. The Taxpayers' Association at once carried its protest to court, and early last month President Judge Frank H. Strouse and Judge Albert Lloyd united in a scathing opinion in which they referred to the questionable ethics of contingent fees and an arrangement whereby the special advisers of the commissioners would have a financial stake in any appeal. They concluded by saying that there was no warrant for the course taken by the commissioners, that the contract was against public policy and beyond the power of public officers and therefore void, and that an injunction should issue restraining the commissioners from issuing warrants for any payment whatsoever to Moser and Monroe for work under the contract, and restraining the County Controller from passing any accounts in favor of them was under the arrangement of last March.

Coal Commission Seeks Aid of Experts to Complete Task at Time Appointed

As the President's Coal Commission draws nearer to the termination of work which it has been assigned to do, the commissioners are receiving a new impression of the enormity of the task and the short time at their disposal. At a time when every hour is precious they are experiencing exasperating delay in obtaining technicians for their staff. It has become evident during the past week that there is no surplus of coal specialists in the country. As a result the commission is being forced to attempt to draft some of the trained men in the employ of the interests concerned. Due to the limited time and the large amount of work to be done a comparatively large staff of trained men must be put to work. There is a feeling that mine operators, the United Mine Workers, exporters and large consumers of coal should be willing to contribute to the success of the commission's work by being willing to make some sacrifice in the way of releasing specially qualified members of their own staffs.

The managing editor of a large newspaper was summarily discharged a few years ago when the general manager of the paper came into the news room on election night and found the managing editor running an adding machine. At a time when there was such unusual need for broad direction in the handling of election returns the man who was paid to deal with the broad aspects of the situation was devoting himself to the most detailed part of the job. It is believed that the members of the Coal Commission are strenuously avoiding any program of work which would allow them to fall into the error which cost the managing editor his job. Plans for the commission's work have not been worked out as yet in detail but it is believed that the commission will subdivide so that the members best qualified to pursue the broad direction of certain phases of the inquiry can specialize on it, while the work in another line will be carried on by other members.

An idea of the task that is facing the members of the commission may be obtained from some of the alternatives between which they must choose. One of the most important questions the commissioners will have to consider is whether or not they will recommend amendments to the anti-trust statute which will permit consolidations and a scheme of collective marketing.

While it is possible that the commissioners will avoid a flat recommendation as to the rates of wage which they may regard as fair, it is certain that they must go deeply into the wage and living-cost questions. In their report they will be expected to discuss and express opinions on such questions as a minimum wage, a guarantee of employment and unemployment insurance.

It is not unreasonable to suppose that they will consider the place of trade unions in the business of coal production, especially when the organization of coal miners exerts such an important influence on the production of two-thirds of all the coal produced in the United States, which, incidentally, is nearly half the world's output. The commission is called upon to probe deeply into the affairs of the strongest labor union in the world.

While nationalization is specified as one of the points on which the commission must report, it is regarded as probable that it will be dismissed without extended discussion, although it is probable that the commission will see in the cry for nationalization a reflection of the course which the public instinctively pursues when called upon to pay unusual prices as a result of manipulations for which it is in no wise responsible.

Another big question with which the commission must wrestle is that of regulation. The commission will be expected to express its opinion as to whether or not coal falls into a public-utility category.

Commission Query to Miners and Operators Asks Data on Wages and Profits

In the effort to find remedies for the ills of the coal industry the President's Fact-Finding Commission, following three conferences with hard- and soft-coal mine workers and operators last week, sent a questionnaire asking both for suggestions.

Accompanying this questionnaire is a letter from John Hays Hammond, chairman of the commission, bespeaking all possible light on clearing up troubles, so that in the end there shall be a square deal for all concerned. The letter says:

"The commission particularly desires your carefully formulated views as to what efficient policy, if any, could or should be adopted by the government relative to the coal industry, having proper regard to the interests of the mine worker, the mine operator and the public." A résumé of the topics upon which the law creating the commission requires facts (*Coal Age*, Sept. 28, p. 503) accompanies the questionnaire.

"The commission desires you to go carefully over this list of topics," the letter continues, "and advise it in writing at your earliest convenience on the following principles:

"(a) What specific data should be secured under each one of the topics enumerated in the law in order to carry out adequately the direction of the law?

"(b) What in your judgment would be the best and most practicable method for the commission to adopt for securing these data?

"(c) What, if any, topics should the commission investigate in addition to those already enumerated in the law, in

order to give to Congress and the public complete information necessary to the proper understanding of the conditions in the coal industry?

"(d) To what extent are you in position to co-operate with the commission in securing necessary data in such manner as will eliminate in the largest possible degree any basis for criticism of the accuracy or the validity of the data which have been secured?

"In addition to the above, the commission further desires you to advise it in writing at some date in the near future, tentatively:

"(e) What in your judgment are the elements that have caused and are causing the acknowledged demoralization in the coal industry and which are working hardships alike upon the parties engaged in the production of coal and the consuming public?

"(f) What in your judgment are the practical remedies that would eliminate any or all the elements that you feel are responsible for the condition?"

J. D. Rockefeller, Jr., Says Miners Should Have Voice in Working Conditions

John D. Rockefeller, Jr., who is resting at Battle Creek, Mich., telegraphed F. Ernest Johnson, secretary of the research department of the Federal Council of Churches, New York City, last week that the grievances of the coal miners in Somerset County, Pennsylvania, are "well founded." "I have urged with all sincerity and vigor at my command," he added, "that the present labor policy of the operators, which seems to me to be both unwise and unjust, be radically altered."

Mr. Rockefeller's telegram was sent in response to a letter sent by Mr. Johnson to the former calling attention to the strike in parts of central and western Pennsylvania and particularly in Somerset County. "As I understand it," wrote Mr. Johnson, "two large companies in particular, namely, the Berwind-White Coal Co. and the Consolidation Coal Co., are so prominently involved that any remedial policy adopted by them would be likely to have a far-reaching influence. Is it not possible for you as a stockholder to take some effective action with regard to the distressing conditions which now exist in Somerset County?"

In replying to the letter Mr. Rockefeller said that he was not now and never had been a stockholder in or in any way connected with the Berwind-White Co., but was a stockholder with a minority interest in the Consolidation Coal Co. As a minority stockholder Mr. Rockefeller said he had no legal power, even if he were so disposed, to dictate the policies of that company. Moreover, he said, "I must concede the administrative rights of management within certain limits of authority and responsibility. Apart from these usual and recognized limitations, whether legal or administrative, I am now and long have been, a believer in the moral responsibility of stockholders."

"In this special case of Somerset County," continued Mr. Rockefeller, "I have not hesitated to accept my personal responsibility or to record my own position. This I have done directly and through competent representatives. I believe that the underlying grievances of the miners in this district are well founded, and I have urged with all the sincerity and vigor at my command that the present labor policy of the operators, which seems to me to be both unwise and unjust, be radically altered.

"It is my understanding that the operators in the Somerset County coal mines have hitherto denied their employees all voice and share in determining their working conditions and any adequate machinery for the uncovering and adjustment of grievances. The day has passed when such a position can justly be maintained by any employer, or group of employers, in a country like ours. I have long advocated, and never more earnestly than now, a labor policy which concedes to the employees in every industrial unit what I believe to be a fundamental right, namely, the right to representation in the determination of those matters which affect their own interests."

The Committee of City employees appointed by Mayor John F. Hylan to go to Windber to investigate conditions left New York City on Saturday, Oct. 28. The committee is headed by David Hirshfield, Commissioner of Accounts. Before going, James Mark, vice-president of District No. 3, United Mine Workers of America, who was in New York City with the Somerset County miners' delegation, sent a letter to Commissioner Hirshfield in which he said:

"By holding public hearings in Windber you may soon obtain facts of the un-American conditions under which coal for your city subways has been mined and you can form your own conclusions as to whether the citizens of New York really want to profit by the suffering of whole communities of coal diggers. We are frank to express our belief that the results of any fair investigation should lead the New York City government to lay down the following policy for the public utilities partly owned by it:

"That a steady supply of good fuel, mined under American conditions, is possible only where operators and miners have arrived at a union agreement."

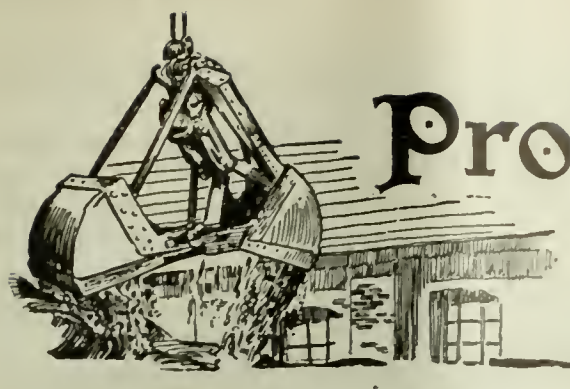
Declaring Strike Off in Mingo, Union Prepares to Move Tent Colonies

Officials of the United Mine Workers began preparations Oct. 27 to move hundreds of miners and their families quartered in tent colonies to union coal fields, as a consequence of the official abandonment of the bituminous strike in the Mingo field.

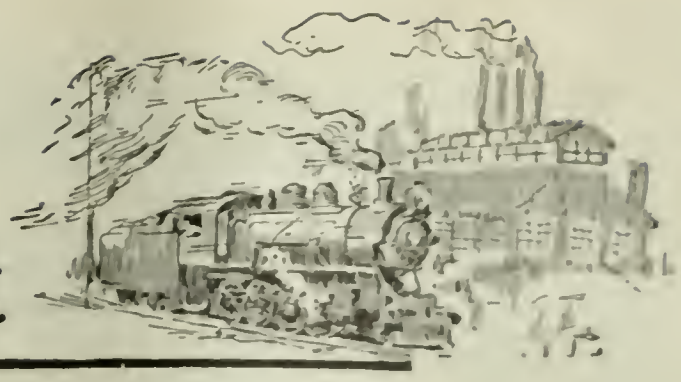
The tent dwellers number approximately one thousand men, women and children, according to R. D. White, international organizer. "We do not intend that these people shall spend a third winter of hardship," said Mr. White.

Decision by union executives to call off the strike was reached at Indianapolis several days ago, it was reported. First announcement was contained in a letter from John L. Lewis, international president, pointing out that the strike has cost the union approximately two million dollars.

During the twenty-eight months of the strike there were thirty known deaths and fifty persons were wounded. Mining equipment destroyed by dynamite and fire was valued at a quarter of a million dollars.



RENEW YOUR MEMBERSHIP



The annual roll call of the American Red Cross, at which its membership is renewed, will take place in the period between Armistice Day, Nov. 11, and Thanksgiving Day, Nov. 30. This is the sole appeal that the national organization makes during the year, in for the purpose of maintaining its membership at a point that will enable it to perform the many great work it is Congress.

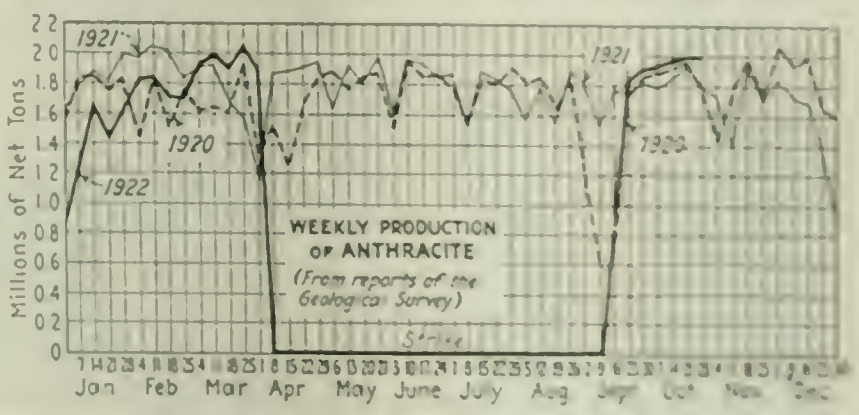
Production and the Market

Weekly Review

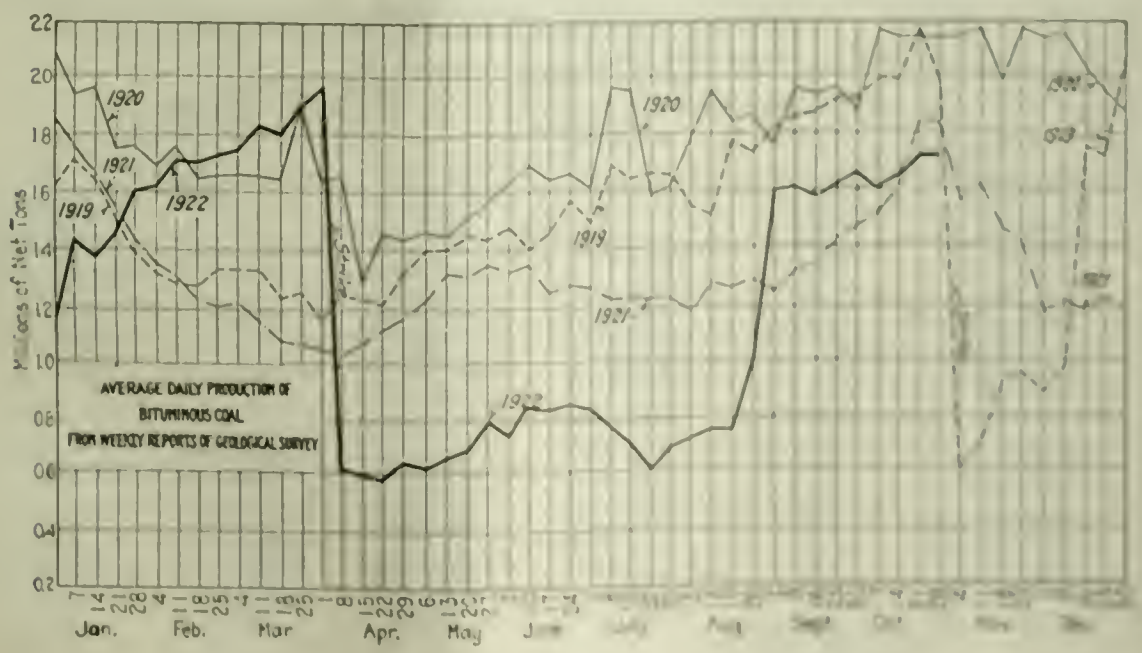
The inherent weakness of the bituminous-coal market is indicated by the wide range in prices. Prices of good grades are still firm while on off grades and the output of small mines quotations are low—that is to say, the market is extremely spotty. In a strong market coal is coal, and it all takes the ruling price. Today the range of prices on the product of mines in the same field varies a dollar or more per ton, depending on quality. *Coal Age* Index of spot bituminous prices receded to 346 on Oct. 30—a decline of 6 points for the week. This corresponds to an average mine price of $4.19. The curve of prices, which since reaching the peak of $6.73 the last of July has been falling sharply, is flattening out. The decline appears to have been largely arrested, partly accounted for by seasonal domestic orders, but also due in part to the firm selling tactics of the largest houses. There is a "take it or leave it" note to the sellers' canvassing today—and good grades are not left stranded.



Market Sensitive to Transportation Conditions

The margin of supply in excess of demand is at a point where any sudden dislocation of transportation has an immediate effect on the market. Thus prices at the Cincinnati gateway were markedly stimulated last week by an embargo placed against the westward movement of coal by the Chesapeake & Ohio. Steam prices quickly rallied to the level of gas and byproduct coal, while domestic fuels skyrocketed. Facilities of the L. & N. and N. & W. were pushed to the limit to meet the emergency and congestion appeared at once.

Federal Fuel Administrator Spens has obtained the co-operation of representative Smokeless, Pittsburgh and Ohio operators in holding down their domestic prices. The market range is narrowing down to this level, but slowly, and with intermittent relapses in such emergencies as the Cincinnati occurrence of last week.



Warm weather has cut the Middle West steam market into ribbons. Producers are eagerly taking domestic orders and sacrificing their resultant coals in an effort to maintain production. Competition is so keen in that section that local producers have crowded West Virginia and Kentucky coals from that market. Improvement in rail conditions is slow and not yet indicative of any general betterment.

Ohio price regulatory laws are proving a burden to the trade. Coal produced in that state is seeking outside markets and a heavy tonnage is moving to the Lake and Michigan points. Ohio retailers are forced to buy outside coals at fancy prices. This involves longer hauls and further taxes railroad facilities and car supply.

Heavy shipments to the Northwest have lulled the consumer to a sense of security and dock sales are slow, despite lowered quotations made in the past ten days. Tonnage is piling up at the Head-of-the-Lakes and there is little buying activity shown, aside from a few large consumers who are stocking.

Domestic sizes of anthracite are in great demand and retailers are unable to maintain their yard stocks. The complaint is heard in the East that concentration of tonnage for the Lakes is reducing receipts to the

expected to show a total of 190,000 cars and indicate a production of 10,400,000 tons."

Approximately 1,000,000 tons of coal reached the Head-of-the-Lakes during October, of which 90,000 tons was anthracite. If this rate is maintained the season's total will approximate one-half of last year's receipts. An acute

shortage of cars is reported by the dock trade. Storage space is rapidly being filled and prices have softened. All-rail tonnage is already an undermining factor in dock prices. Buyers are apathetic and aside from a few large

*[illegible] †Advances over previous week shown in heavy type, declines in *italics*.

Coal Age, Index 346, Week of Oct. 30, 1922. Average spot price for same period, $4.19. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions each of slack, prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

consumers who are taking stock the Northwestern market for soft coal is becoming sluggish.

Lake dumpings were 1,011,051 net tons during the week ended Oct. 30, as compared with 1,004,094 tons in the preceding week. The season's movement to date is 14,474,345

tons; last year it was 21,461,460 tons. Of this quantity approximately 1,050,000 tons has been forwarded to parts not ordinarily taking Lake coal.

All-rail shipments to New England declined to 3,092 cars during the week ended Oct. 21, as compared with 3,646 cars in the preceding week. Shippers are finding few takers for their tonnage, although prices have declined steadily.

Hampton Roads dumpings for all accounts were 292,560 net tons during the week ended Oct. 26, as compared with 260,358 tons in the previous week. The Sewalls Point piers registered an increase, while the Norfolk & Western tonnage dropped. There is less coal on hand, although it is likely that the Chesapeake & Ohio embargo on westbound movement will throw more tonnage to Tidewater. Coastwise business is still the mainstay of the Roads, and the low prices prevailing afford Southern fuels an excellent competitive position in New England with all-rail grades. There is little activity in that market, however, aside from contract movement.

How the Coal Fields Are Working

ANTHRACITE

Estimates of production of hard coal for the week ended Oct. 28 place the output at 2,100,000 net tons, as compared with 2,003,000 tons during the preceding week.

Domestic coal is moving out to householders as rapidly as it is received by retailers. Canada and the West are clamoring for coal—and receiving but little. Lake movement is being pushed during the short remainder of navigable weather this season. This has caused a diminution of receipts at Eastern points and while there is no actual suffering, federal authorities are understood to have been requested to increase the allotments for New York State. Rail deliveries to New England were 3,477 cars during the week ended Oct. 21, as compared with 3,256 cars in the preceding week.

COKE

Production of beehive coke was 211,000 net tons during the week ended Oct. 21, an increase of 20,000 tons when compared with the preceding week. The largest increase occurred in the Connellsville region.

Contract offerings are higher than spot prices, in view of transportation difficulties to be expected later. With increasing output the market hinges on the position of the consumer, whose outlook, while not poor, is uncertain. The market for pig iron is sluggish. With increasing production it is no longer a question of obtaining sufficient coke and steam furnaces may have to blow out because of a lack of market.

Foreign Market And Export News

Good Export Demand Aids British Market; Production Sets New High

The prospects of the Welsh coal trade are still bright, the only fly in the ointment being the threat of a strike on the non-unionist controversy. It is believed that the Miners' Federation will decide to postpone the threatened strike. The export trade continues strong, especially to South America, Europe and Mediterranean, sailing despite, on the other hand, exports to the U. S. and Canada have declined from around 200,000 to 60,000 tons per week.

The chief market is found in steam coals which are going to Germany, France and Italy. These countries, it will be remembered, first held their orders for a fall in prices, then were crowded off the market by American orders, and so their requirements now are heavy.

British production during the week ended Oct. 14 set a new record for the year when a total of 5,235,000 gross tons was mined, according to a cable to *Coal Age*. The preceding week's output was 5,109,000 tons.

The situation in North England enables sellers to hold for advances on current quotations. The perennial labor uncertainty in Wales has greatly helped Northumberland and Durham and there is a strong demand for practically all classes of coal.

French Coal in Better Demand

Nord and Pas-de-Calais coals remain very active, orders are easily absorbing the production and small tonnages are being taken from stocks. The demand for domestic, stirred up by the difficulty of procuring Belgian coals, has become pressing and delays of delivery of two or three weeks are common.

Welsh machine-made anthracite nuts are selling now on the basis of 80s. c.i.f. Rouen, or 282 fr. and are retailed to Parisian households at prices varying between 300fr @ 340fr. The excess of this price has induced consumers to purchase Belgian anthracites instead, which are now almost unobtainable.

In the Center fields, stocks of industrial coals are still large, but those of domestic coals are rapidly decreasing. Nevertheless, a certain improvement in the industrial demand in that district also begins now to be felt.

Although French operators of the Nord and Pas-de-Calais have agreed not to press for the present their former decision to reduce wages, they are determined to obtain from Parliament the amendment to the Mines Act, which would increase the underground working time. Miners are no less opposed to any modification of the Act.

Hampton Roads Export Clearances, Week Ended Oct. 26, 1922

Nor SS. Jose Kingston, 1,181 tons.
Br SS. Berwindvale, Havana, 7,814 tons
Amer Schr. James M. W. Hall, Hamilton 458 tons
Amer Schr. Grand Turk, Hamilton, 758 tons
Amer SS. Cristobal, Cristobal, 9,485 tons.

Coal Paragraphs from Foreign Lands

GERMANY—Production in the Ruhr region during the week ended Oct. 14 was 1,972,000 metric tons, according to a cable to *Coal Age*, as compared with 1,855,000 tons in the week preceding.

ITALY—Genoa quotations on Cardiff steam first are now around 40s. 6d., according to a cable to *Coal Age*. Last week's price was 39s. 6d.

BELGIUM—The market is becoming very firm and orders are of extraordinary size. After a year of crises the Belgian coal basins are enjoying a period of exceptional prosperity. The foreign demand for classed descriptions is growing.

Receipts Overabundant; Market Conditions Muddled

Higher Grades Well Sold Up—Prices Easy on Other Qualities—Heavy Users Active, Average Consumer Still "Lying in Wait."

Prices are easy, except on the higher grades, which are not in oversupply. Receipts are still more than adequate, but the consumer insists on quality coal, with the result that good fuel is well sold up. The market is badly muddled and a wide range of prices is quoted, especially for medium- and low-grade fuels. Heavy users are the most active and are still the saving feature in the situation, as the average consumer remains on a hand-to-mouth basis.

British coal receipts are diminishing, but some heavy consignments still seek an outlet. Southern coals are coming forward in good volume, but only on order.

NEW YORK

Demand was spasmodic toward the end of the week. Quotations changed as frequently as the temperature and cool weather caused a slight stiffening. The general trend indicated little change from the previous week, although quotations in some instances were lower and the range wider.

The tendency of buyers to stay out of the market continues but most dealers look for considerable activity the early part of November. One feature of the market was the apparent unwillingness of some operators to book orders although given the order at the quotation they had made. While this action may have been due to heavy orders already booked or otherwise no reason was given to the middle houses offering the orders.

Receipts of British coal are growing less each week, but it is said there is considerable here still unsold. Southern coals are coming in good volume and on order.

There were upward of 1,500 cars at the various piers on Oct. 27 with no large surplus of the better grades. Boat rates in the local harbor are stronger, due to the many boats loaded with anthracite steam coals.

PHILADELPHIA

The situation continues to be badly muddled on account of the average consumer's attitude toward ordering. On the other hand there are actually instances of consumers who are short of coal and have come into the market in great haste to replenish supplies. Often these are users of the highest grade coals and they have not been plentiful at any time. Car supply is still a severe handicap on production, but there are some signs of improvement.

The users of heavy tonnages are still in the market and are really the saving factor in the situation. The producer is still inclined to criticize the ordinary consumer, because in the shortage that all feel sure is to come before midwinter, with the consequent upward bound of prices, it is the man without coal who cries the loudest, yet is short of coal on account of his own shortsightedness.

Each week seems to turn up consumers who have adopted oil as a fuel, wholly or partially, although the installations to date are not sufficient to make any impression upon coal consumption.

Prices have eased off a bit, and the slight firmness evident ten days ago, has vanished. High-grade coals continue to lose the least ground, as the most of this tonnage is applied on contracts and very little reaches the spot market. Recently some cheap offerings have been made, likely the output of wagon mines.

BALTIMORE

Bituminous coal demand is weak and prices have softened further. Consumers are buying on a current basis only although some of the large users are continuing to take advantage of the ruling prices and are putting in reserves.

Pools 9 and 71 are quoted $3.75@$4.25, net mines; Pools 10 and 11 are $3@$3.75; Pool 64, $3.25@$3.50, and Pool 63 is $3.50@$3.75.

Car supply is very short and deliveries slow and uncertain. Despite this, however, sufficient coal is being received to meet all spot demands. Good grades move the easiest; lower-quality coals are often in distress on the present sluggish market.

FAIRMONT

Operations are limited to about one or two days a week and many mines are unable to operate even that much. Some are forced to go without loading equipment for more than a week at a time owing to the general practice of the roads in assigning cars for railroad fuel loading. There has been little or no change in the market situation. The prevailing price on steam mine run for Western delivery is $3.75. In Eastern markets it ranges $3@3.50.

UPPER POTOMAC

Managing to secure a more regular supply of empties, plants in the Upper Potomac are operating with less interruption than is the case elsewhere in the state. Production is on a smaller scale in the Georges Creek region, not because of a shortage of cars but because of the fact that the strike trouble has not been entirely eliminated. There is still lack of pronounced activity in buying in the East although mines are not falling behind any on that account.

CENTRAL PENNSYLVANIA

Prices show a further decline. Prices to local consumers in the district are due for a drop because of an order issued by the I.C.C., effective Oct. 25, which does not permit the placing of open-tops or hoppers on sidings for operators unless they can be loaded within 24 hours. This order will force many wagon mines out of the market as many of them cannot load a car within the specified time.

Pool 18 is now quoted $3@$3.25, f.o.b. mines. Pool 10 ranges $3.75@$4.

West

KANSAS CITY

Snappy temperature stimulated the demand for domestic coal and dealers are rushed to take care of orders. The demand was also aided by orders from customers who changed to oil-burning equipment that failed to perform as provided and who went back to coal.

Demand for steam coal is holding up and all are being supplied. Aside from delay in transportation the coal business in this section is in a more active condition than for some time.

Prices are too low to yield any revenue to either the operator or retail dealer. At the same time the public is kicking about the price being too high. The strike put a lot of new coal operators in business. Most of them run small mines, and as they keep no cash accounts, they will not know that they are broke until they run out of money to meet their payroll.

SALT LAKE CITY

Mines are working on an average of less than three days a week. Car shortage is steadily growing worse and the market is also weak. The coast trade is falling off, while the demand from neighboring states is very slight compared with what it was. The ideal weather which prevails, together with the reopening of the Wyoming mines, is largely responsible for this.

Salt Lake City yards have about 15,000 tons now, which is less than in former years. Consumers have been waiting for the Grand Jury to finish its investigation of high prices. Now that it recommends price fixing by the governor, they will no doubt wait for that though lump is in better call already. The demand for slack is weaker.

DENVER

Instead of cars being delivered to Colorado mines enabling them to work on a percentage basis of from two to three hours a day, the Union Pacific on Oct. 23 started distributing cars to a certain number of mines all day and the balance of the mines the next day. This enables the operators to reduce the cost of production during the car shortage.

Business on first-grade lignite is practically at a standstill as most of the dealers are buying second-grade lump at $3 per ton. First grade is quoted at $4.90. Many Denver operators are getting inquiries from Omaha dealers for quotations on lignite slack. This would indicate from this point that there is an unusual shortage in the supply of cars in Illinois and Iowa

Anthracite

Domestic Business Brisk; Receipts in East Lower

Retailers Hard Put to Maintain Yard Supplies—Efforts Bent to Get Coal to Northwest—New York May Ask Increased Allotment.

Domestic business is very active and retailers are unable to maintain their yard supplies. Eastern centers complain of diminished receipts, which probably will be the case until the close of Lake navigation, as every effort is now being made to send coal to the Northwest in the few remaining weeks of the season. Canadian buyers are unable to place orders for a satisfactory tonnage except at high premiums.

So much of the coal received at New York terminals is transshipped to New England that there is a rumor that the federal authorities will be requested to increase the allotment for that state. Steam business has been aided by the cool weather, but mine-storage space is still being utilized.

PHILADELPHIA

Heavier receipts have increased the seriousness of the situation. Dealers are being heavily pressed for fuel, and it is necessary to ask the buyer to take what is on hand.

The shippers, especially the companies, have but the one answer for the short shipments, that being the movement to the North and to the Lakes, before winter sets in. This year, on account of no summer shipments, dealers are inclined to criticise the action of the shippers. The outlook cannot be said to be promising.

There is some tendency to a strengthening of retail prices. While most sales are being made \$14.50, those dealers who had been inclined to waive the carrying charge are now more particular.

Steam sales have not improved, with companies still making use of their storage yards to a limited degree, and the other shippers selling some coal off grade.

BUFFALO

Demand is of course heavy, but it is not as insistent as it sometimes has been. Distributors still say they cannot keep up with the orders that come in from people who have no coal.

Canadian dealers despair of getting anything like a supply. One of them states that he usually sold eighty cars a year, but so far he had received only one and he thought he would do well to get twenty before moving.

Lake shipments for last week were 129,500 tons, of which 61,700 were for Duluth and Superior, 4,300 for Port Arthur and 4,000 for Marquette, on Lake Superior and 20,100 for Chicago, 14,800 for Milwaukee, 7,800 for Sheboygan and 2,700 for Racine on Lake Michigan.

BOSTON

While certain of the originating companies are making good deliveries by water, the all-rail route seems to be pretty well gummed up with the shortage of motive power. On the New Haven R.R. it is taking three and four weeks for cars to come through, and in parts of the anthracite region there is genuine alarm over car supply.

Most of the Boston retail dealers marked up prices on Oct. 24 from \$15 to \$16 per net ton delivered. A few of the larger distributors have not yet advanced.

BALTIMORE

Domestic supply is very short. Receipts average about 4,000 tons daily and dealers are unable to supply more than a portion of the demand.

Many householders are without fuel, as they have declined to purchase the soft-coal substitutes recommended by the Maryland Fuel Distribution Committee. The feeling has prevailed that last-minute supplies of anthracite would be available, but now that colder weather is at hand, a better distribution of these bituminous substitutes is anticipated.

NEW YORK

While the Metropolitan District may to all appearances be receiving its share of domestic sizes, it is rumored that appeals will be made to the Federal Fuel Administration in Washington to increase its allotment. Consumers, while not yet suffering from a lack of fuel are becoming anxious, especially those who so far have not been able to get even the 30 days supply allowed by the New York State Fuel Administrator.

Some of the independents and their sales agents are refusing to take orders unless it is understood that shipments cannot be expected inside of at least three weeks. Demand from the West and Lake ports, as well as New England, remains heavy and efforts are being made to get as much coal as possible into those sections before winter sets in.

Retail dealers are taking comparatively little of the high-priced individual coal. Some of the smaller operators are asking around \$12, but the larger independents are quoting \$9.25 @\$10.50.

The steam coal situation is easier. Storing continues but there is a heavier consumption because of the cool weather. A heavy tonnage is also being taken by retail dealers who in doing so are able to secure shipments of the larger coals.

British coal is being featured as a substitute for anthracite. The Consolidated Coal Importers, Inc., is offering "dry semi-anthracite Welsh coal" in the New York market at \$14.50 per net ton, delivered to consumers, and advertising for salesmen to handle this fuel at a "liberal commission."

Coke

UNIONTOWN

The coal market appears to have touched rock bottom with the \$3 figure which has been prevailing for several weeks. Demand continues uncertain but operators have successfully resisted any further price lowering.

A distinct development of the week was the I. C. C. order which closes the transportation lines to wagon mines. The order denies open-top cars to wagon mines until tipple mines have been given maximum placements.

The coke market continues a bit slippery but its softened condition has not yet reacted against production. There is, however, a firm resistance to prices.

Indications are that contracting for coke tonnage will be resumed again Jan. 1 after suspension of practically a year. At the opening of last year contracts generally were made for only three months owing to the contemplated strike April 1. There were no further contracts during the year when production was interrupted and recovery from the strike was too late to permit last quarter contracts.

CONNELLSVILLE

Connellsville furnace coke, after breaking from \$12 to \$8 in less than a fortnight, has merely weakened a trifle in the past week. The first sign of weakening naturally took buyers out of the market, while the sharp price decline seems to have brought them in again.

Odd lots can usually be picked up at \$7.50, but a good-sized tonnage, particularly if distributed over a week or two in point of shipment, would probably command \$8 without much difficulty. So far as concerns the views of operators, an important point is that with prompt coke at not over \$8 operators are quoting \$9 on contracts running to the end of the year. Their explanation is that there is likely to be a fresh and additional car shortage in December, which would advance the prompt market.

With the steadiness in increased production, it is plain that the future prices depend chiefly upon the position of consumers, whose outlook may not be poor, but is plainly uncertain. There is very fair production of merchant pig iron now, and while recently the whole situation appeared to be simply one of each furnace getting into blast as soon as it could secure coke, it is now not certain but that some of the furnaces may have occasion to blow out.

The *Courier* reports production during the week ended Oct. 21 at 101,310 tons by the furnace ovens and 45,410 tons by the merchant ovens, a total of 146,720 tons, an increase of 6,010 tons.

BUFFALO

Some of the local byproducts are crowding their ovens past the needs of their furnaces and selling the surplus for domestic use at about \$12 for furnace grade. Consumers feel that all coke is held too high, and so do not buy except as a necessity.

Chicago and Midwest

Market Weakness Spreads Into Bigger Sizes Also

Hold-Out of Steam Buyers Lowers Steam, Egg and Some Mine Run, with Screenings—Domestic Firmness Stays —Car Service Unimproved.

Continued summer weather during the past week in this region conspired shamelessly with the big steam buyers to keep the market in most centers of the Middle West low and uninteresting. Even domestic demand, while good, is not rushing, and the difficulty which many producers found in disposing of everything but lump drove them to lower quotations on steam egg and mine run as well as screenings, which have been sliding for weeks. Competition between fields of Illinois and Indiana for skimpy markets is having the inevitable effect and little coal from outside is getting into the Middle Western states.

Kentucky is less afflicted by these conditions because its own local markets are a bit stronger and the call from the Lakes continues good enough to absorb much of the slim production permitted by a 20 to 30 per cent car supply. Gas and by-product coals have dropped some, however. The railroad service of the whole Middle West is about what it was a week ago.

CHICAGO

"The world's greatest coal market" continues to drone along without much excitement. Almost all domestic sizes are in good demand with no noticeable softening in prices. The standard quotation on southern Illinois lump remains at $5.50 and at $4.75@$5.25 on lump from central and northern Illinois and the best districts of Indiana. There is no mad rush on, however. Small quantities of anthracite and smokeless dribble in, but here again there is no crush at the retail coal man's door. The smokeless even shows signs of weakening a little from $6@$7.

Steam buyers, having already lowered the levels of screenings week by week by staying out of the market, have effected further reductions from several fields so that the best southern Illinois screenings today are down to $2.50 and even to $2.25 in some instances. The same sizes from other Illinois fields remain below $2. Steam egg and mine run has weakened here and there also, for there is no class of consumers for these coals that is laying in supplies. Competition between Indiana and Illinois producers grows keener with reports of many price concessions on almost everything under 6-in. lump. Not much Kentucky coal reaches this far north for the market is saturated now and nearby fields have got prices down low enough to discourage outsiders.

The retail market is worried by the Pottinger-Flynn yards offering coal "at cost" through the medium of coupons in a local newspaper. This concern has been accused, before a grand jury, of selling coal unfairly to the city schools. The company is now busy staving off a jail sentence imposed upon its auditor for refusal to produce certain company books.

WESTERN KENTUCKY

While some of the operators are kicking about the buyers' strike, as a matter of fact production is as heavy as car supply will permit, but prices are not what the operators would like to see them. The Illinois Central is supplying about 34 per cent of the normal number of cars and the L. & N. 20 to 25 per cent.

Steam coal is a little stronger due to cooler weather and development of small steam plant demand for heating use along with better demand for mine run from domestic consumers. Screenings are $1.75@$2.25, including pea and slack as well as nut and slack. Mine run is stiffer at $2.75@$3, but is perhaps shaded a little under that price, although some houses are quoting as high as $3.25. Lump is quoted from $4.75 for poorer grades to $5.50, but not much coal moves at the top price.

ST. LOUIS

Warm weather has brought an easy market with everything in surplus. Even Carterville seems to be plentiful and the dealers are not buying for storage. The public seems to have a feeling that coal will soon come down and are buying only in small lots and this feeling is conveyed to the dealer, who is not putting much coal in storage.

The public seem to think that the retail price of $9.50 on Carterville as against the next lower grade, which is Mt. Olive, at $7.50, is too much and the demand is for Mt. Olive. Standard at $6.75 is not popular. A few cars of anthracite are moving in, but no smokeless and nothing from Arkansas. Country domestic is also quiet and the call is principally for the cheaper coals

Locally steam is easy. Large users are not buying beyond actual requirements, and this is true to a great extent of country business. Railroad tonnage is light on account of restrictions against certain roads which are practically embargoes and transportation west of the river is far from being good. Colder weather is the one hope for any improvement.

LOUISVILLE

While prices are a little stiffer on general steam coals this week demand for gas and byproduct has slumped somewhat, and gas coals are selling at about the non-gas price except on mine run straight steam coal which is quoted as low as $4 for eastern Kentucky, while the gas coal is quoted at $4.35@$4.50. Lump is firm at $6.50@$7, while screenings are commanding the mine run price, because of small production and steady demand from consumers who use automatic stokers.

It is reported that there is better buying from eastern Kentucky for railroads in Ohio and the North. While the market is firmer, it is not materially stronger. It is reported that there is not much coal on tracks, and with car supply between 20 and 30 per cent, production continues small. Some movement is going South, to the textile districts which are busy. Lake movement continues fair.

Western Kentucky prices are quite firm in the local market, at $4.75@$5.25 quoted, with some lump at $5.50; mine run is $2.75@$3, and screenings, $1.75 @$2.25. Most western Kentucky coal is moving either South or to Louisville, but production is low due to a car supply of from 20 to 34 per cent on the various lines.

Industrial lines are active and plants are busy, and apparently consuming fuel, but even with present small production there appears to be no shortage.

SOUTHERN ILLINOIS

The warm weather has put a crimp in business as far as smaller sizes of coal are concerned in the Carterville field. This has also affected the nut size, which is becoming almost as topheavy as screenings. There are no billed screenings and nut at many mines and screenings have dropped to $2 while nut is quoted as low as $4.

The average car supply throughout the field is three days at mines having two or more connections, while it runs from 1½ to 2 days at mines with only one connection. Railroad tonnage is light and the bulk of the movement seems to be North and Northwest. In the Duquoin and Jackson County field conditions are similar.

In the Mt. Olive district steam sizes are causing idleness. Railroad tonnage is good and up until the last few days domestic movement has been fair but the hopper-bottom equipment and the warm weather put a quietness on the movement of domestic, especially to the St. Louis market.

In the Standard district conditions are beginning to look bad. Steam sizes are heavy and many mines are carrying "no-bills." Embargoes on the lines west of the river have caused some trouble, but, generally speaking, there is no demand for steam coal and right now the domestic business is easing up. Railroad tonnage is fair. Car supply both in the Mt. Olive and Standard districts average 3 days a week.

INDIANAPOLIS

There has been little change in the Indiana market. Jobbers, operators and retailers all unite in the assertion that demand is light. From the retailer's viewpoint the warm weather is undesirable. The jobbers say there is no stocking demand for steam coal from industries. Prices show no change, but there has been a little weaker tendency in some of the grades.

There is a hue and cry from all sections of the state for cheaper coal. Many factory executives say they will further curtail production unless there is some concession made. Utilities are buying from hand to mouth and are beginning to demand permission to raise rates.

Eastern Inland

Meager Spot Offerings Absorbed at Firm Prices

Marketing Orderly, Dependent on Car Supply—Domestic Market Active—Steam Trade Improves—Conditions Mottled in Ohio—Lake Loading More Difficult.

Current production is being marketed in an orderly manner, regulated by the short car supply. Prices are firm, demand being sufficient to absorb the meager spot offerings. The domestic market is very active and there is a little more life to the steam trade.

Ohio's price-fixing regulations have caused a serious domestic situation in that state. Ohio-mined coals are seeking other markets and retailers thus are forced to buy coals produced in "foreign" states and at high prices. The longer rail haul involved is further taxing poor transportation conditions and shortening the car supply. Loadings at Lake ports were hampered by last week's weather conditions.

CLEVELAND

One direct consequence of the fuel control and price fixing in Ohio has been a steady flow of Ohio-mined coal out of the state. Retailers from other states declare they are buying quantities of Ohio coal at $5.50@$6. That explains why Ohio dealers can get little good Ohio coal at the rates of $5.50@$6.11 for prepared sizes, as fixed by the Ohio Fuel Administrator. As a result Ohio retailers are compelled to buy much of their fuel outside of the state.

Dealers are complaining that the margin of $2.75 a ton allowed in Cleveland is too low to enable them to do business. They assert that the cost of handling all grades of coal was $3.37 a ton during September, as compared with $2.56 in 1917, when labor was more plentiful.

Demand in this district is somewhat better. Householders are buying more and there is a somewhat better call from industrial users. The latter, however, are still buying on a hand-to-mouth basis.

The Lake movement continues around 1,000,000 tons weekly. Shipments for the season up to Oct. 27 were 12,852,130 tons compared with 20,197,169 tons for the same period of 1917 and 18,240,244 tons in 1916.

COLUMBUS

A tendency toward stronger prices on prepared sizes and a softening influence on mine run and screenings are the chief features of the Ohio coal trade. Hocking and Pomeroy grades are selling $5.50@$6. Practically none of the coal is coming to Ohio dealers because of the price fixing which is causing operators to seek a market outside of the state. Efforts on the part of the Ohio and federal fuel administrators to get together on Ohio prices have not been successful so far.

Steam grades are weakening because of a larger tonnage of mine run thrown on the market. Some of the commercial users are stocking up to a limited degree but most of the purchases are for current needs.

The Lake trade is going along fairly well and some few additional contracts have been made. A fair tonnage is being moved and it is believed there will be no fuel shortage in the Northwest especially in view of the all-rail shipments which will continue during the winter.

DETROIT

Although receipts are heavier neither the steam users nor retail dealers are displaying much interest in the matter of adding to their stocks. Orders are coming irregularly and the business handled is largely on a hand-to-mouth basis. Buyers apparently are persisting in the waiting policy which has been a strong characteristic of the local market since midsummer.

Most of the coal which is now being sent to Detroit comes from mines in Ohio. The supply of West Virginia and Kentucky coal is limited by the facilities of transportation lines serving those sections.

Hocking lump and egg is quoted at $5.50@$6; mine run is $3.75@$4; nut, pea and slack, $3.25@$3.50. Fairmont 2-in. is $5; mine run, $4.50@$4.75; slack, $4.50. Pittsburgh No. 8 2-in. is $5; mine run, $4@$4.25; slack, $3@$3.75. West Virginia and Kentucky lump and egg is $6@$6.25; mine run, $4.75; slack, $4.50@$4.75. Smokeless lump and egg is around $8, with mine run, $6@$6.75.

Receipts of anthracite continue far short of requirements. Retail dealers are refusing to make purchases from independents who quote $12 as the mine price.

EASTERN OHIO

Car shortage and transportation disability are again the prime factors preventing a more normal output. During the week ended Oct. 21 mines produced 318,000 tons or only 49 per cent of potential capacity. Statistics covering cumulative production since Jan. 1 indicate that this field has produced only 5,197,000 tons out of a potential capacity of 25,377,000 tons or 32.3 per cent. Efforts are being made by the Ohio Fuel Administration to increase the car supply and thereby avoid the possibility of an acute fuel shortage this winter.

Considerable anxiety and agitation have developed with respect to available supply of prepared sizes. Because of the low maximum prices fixed by the Ohio Fuel Administrator on coal sold within the state the major portion of such coal is being shipped out of the state where better prices are offered.

Retailers are compelled to purchase considerable quantities outside of the state to meet the requirements of their trade and the railroads are being called upon to perform unnecessary transportation service.

Inquiries have now reached the highest point of the year and such a widespread demand exists that it is impossible to fill at the present limited rate of operations.

Bituminous coal receipts at Cleveland during the week ended Oct. 26 amounted to 1,620 cars, an increase of 149 cars over the preceding week. Industries took 1,281 cars and 339 cars were consigned to retail yards.

In the Lake trade some time was lost during the week because of weather conditions and total dumpings were lower than they have been in some weeks.

BUFFALO

Consumers do not buy as shippers feel they should. The claim on one side is that cars are so short that anything worse in that direction would make it impossible to ship coal enough to keep the supply up, but the consumers affect to believe that the cry of shortage is merely to produce a market for the excess of coal that is coming out of the mines. It is to be hoped that neither party is quite right about it and that the trade will somehow manage to keep going till the movement of cars is more free.

Prices fluctuate. A few strictly Pittsburgh shippers manage to keep up to $5@$5.25 for Youghiogheny gas lump and $4.75@$5 for Pittsburgh and No. 8 steam lump, and sometimes even a little higher, but the bulk of this coal is selling a trifle below these figures. Allegheny Valley mine run is $3.60@$3.85, with all slack $3.25, adding $3.24 to Pittsburgh and $3.09 to Allegeheny Valley for freight.

PITTSBURGH

The local situation is quite devoid of important developments, as has been the case for several weeks past. Production is proceeding in an orderly manner, regulated by car supply, which technically is short but practically appears to permit of consumers' requirements being taken care of very well. The orderly character of the movement is indicated by the fact that demand for odd lots in the open market is relatively small, indicating that consumers are well supplied by their regular sources.

Prices are holding up very well indeed, considering the lightness of demand in the open market, and may not show any further change until the ending of the season for Lake shipments brings about new conditions.

Ordinary steam coal is $3@3.50, depending on quality and tonnage, by-product, $3.50@$3.75, good grade gas coal running up to $4, with still more paid for special qualities, making a general market range of $3.75@$4.25; domestic 1¼-in. lump, $4.75@$5.25.

NORTHERN PANHANDLE

Mines still find it a difficult matter to secure an outlet to Western markets and particularly the Lakes, owing to freight congestion. There is a somewhat better demand in the West. As in other fields, the car supply is none too good, a large part of the product loaded being for the railroads, with mines loading that class of coal securing a somewhat better supply than others.

Northwest

Docks Are Jamming and Buying Continues Slow

Lake Shippers Now Fear Trouble When Cold Weather Starts a Rush—Fewer Cargoes En Route—Temporary Slump in Bituminous Prices.

Markets are sluggish on bituminous coal with the result that the heavy cargo shipments of the past six weeks have piled the docks fairly high. This condition, which appeared about a week ago, is getting troublous. Prices in some cases have softened further, especially on a few large deals in steam sizes, and are expected to drop within a week or so on coals that cannot stand storage. This general situation is shutting off shipments from lower ports to an extent and is expected to cause trouble when the first stiff cold comes, as the fuel supply for this region can hardly be ample if shipping does not continue heavy until Dec. 1.

Considerable quantities of anthracite are reaching the docks. There is no such public apathy over hard coal. Instead, the scramble to obtain it has grown almost exciting. Prices generally remain firm with a slight upward tendency, though there is no skyrocketing.

DULUTH

More than 3,000,000 tons of coal now lie on the docks at Duluth-Superior harbor because consumers are slow and coal men are beginning to fear that the docks will be full before the close of navigation. The capacity of the harbor docks is but 7,500,000 tons. Shipments will slowly drop off. Last week forty-eight cargoes were received of which eight were of anthracite, but only eighteen are reported on the way of which two are hard coal. A week ago more than thirty cargoes were on the way here. Not enough coal has gone out to insure a plentiful supply, and coal men believe there may be a $2 increase in bituminous before Feb. 1. Consumers, of course, are waiting for a drop in prices, and base their hopes upon the jamming of the docks, which usually indicates plenty.

Despite the prediction of increased prices, at least one dock cut $1 a ton to move run of pile to two public utilities on an aggregate contract of about 15,000 tons. The run of prices for both bituminous and anthracite is firm, with the exception of quotations on Hocking screenings which are weakening, because of the danger of fire in large stock piles.

The anthracite market is chaotic. Those with orders placed are getting coal as best they can. It is thought, though, that the emergency will have passed in a week or two. Bituminous inquiries are beginning to leak in from independent iron mining companies on the Mesaba range that are slow to order. The steel corporation is receiving much coal indicating that the mining season will be active.

MINNEAPOLIS

The market here is sagging and weaker under the arrival of good stocks at the docks, and a lack of support from buyers. Another undermining factor is the showing from the all-rail trade, in placing a considerable tonnage here. As a result dock interests have begun to make concessions.

Indications are that the docks at Duluth and Superior will have perhaps 5,000,000 tons of coal in another five weeks. That quantity is not equal to any normal winter's needs. But this is not a normal winter in demand so far. The railroads cut down consumption during the late summer by taking off about seventy trains, some of which were out of service for three months. Industries have been running cautiously for some time, and have made their fuel last longer.

The car situation has cut down the movement from the mines or there would be a much larger movement, both from the docks and from the all-rail fields. But despite this handicap, there has been a large amount of all-rail coal moved into the Twin Cities from the Illinois fields. Around 100,000 tons of hard coal have been received on the docks so far, and the Northwest may count upon perhaps 40 per cent of a normal winter's needs of hard coal. Some of this may have to be moved all-rail.

MILWAUKEE

Mild weather seems to soften the popular clamor for coal, but dock men remain in an uneasy frame of mind. Fifteen cargoes of anthracite, aggregating 117,904 tons, reached port in October. This coal is being rationed out to retailers, who, in turn, are restricting deliveries so as to spread the supply. The price of anthracite continues unchanged.

There has been a slight check in the movement of soft coal, due to the fact that receivers have not been buying much during the past two weeks. The docks are fairly well filled.

October will show up well in coal receipts. Thus far fifteen cargoes of anthracite and sixty-three cargoes of soft coal have been unloaded, the soft coal tonnage aggregating 560,416 tons. Cargo receipts for the season thus far aggregate 118,614 tons of anthracite, and 1,831,371 tons of soft coal, against 842,550 tons of the former, and 2,273,902 tons of the latter during the same period last year.

The City of Milwaukee remitted a penalty of $2,700 imposed on the Callaway Fuel Co. for coal furnished which did not come up to the standard of thermal units. The company claims that the pooling system makes it impossible to guarantee the quality.

New England

Little Change in Market; Inquiry from Small Users

Certainty of Car Shortage Causes Many to Realize Prices Are Near Bottom—Receipts of British Coal Wane—Adverse Criticism Heard.

November shows little change in the current market. Inquiry is still scattered and confined generally to small users who figure that with possible car shortage present prices are about as low as can reasonably be expected, at least for the near future.

Receipts of British coal are steadily diminishing and by another fortnight, it is reported, the last cargoes will have been received. There is much complaint over some of the grades shipped; in fact delays on certain of the railroads out of Boston have been attributed to the character of the coal.

Apparently none of the corporations is buying spot coal, except in sparing amounts, and persistent canvass discloses very little prospect for comprehensive purchases the next thirty days. The number of steam colliers tied up at this end is one indication of the poor outlook for steam coal the balance of the season. A fair amount of coal is coming forward on contract, but almost none at all on current purchases.

There is a little buying of Pennsylvania grades all-rail, although prices are at what would have been considered a few weeks ago a very low point. A few quality grades are being moved at remunerative prices, but this means a range of $[illegible]@$4.75 per net ton f.o.b. mines. Among the medium coals there are some of very good reputation that are an easy purchase at $3.50@$3.75.

Pocahontas and New River still show large accumulations at Hampton Roads. Judging from the market here these will continue to be heavy throughout the month. There are reports of car shortage on the Southern roads, but not as yet has the lack of equipment in any sense affected the spot market in New England.

While Navy Standard at Newport News and Norfolk sold as low as $3.65 per gross ton f.o.b. vessel a week ago, there is a feeling in the trade that the market has strengthened a bit and that $7 is a fair average price for high-grade coal.

Cincinnati Gateway

Prices Spurt with Embargo To West on C. & O. Coal

Buying of Coal from Southeastern Kentucky and Off N. & W. Gains—Steel Mills, Utilities and Lake Buyers Evince Interest—Smokeless Has Odd Price Range.

Prices took a decided spurt when increased buying of southeastern Kentucky coal as well as that off the N. & W. resulted from the embargo placed on the western movement of coal originating on the C. & O. Immediately there was scurrying by steel mills, public utilities and large consumers that had been using C. & O. coal. Besides this Lake buyers showed added interest and the whole combination moved the price up a dollar a ton within the space of three days.

For the first time in weeks steam coal was selling within the range of the gas and byproduct. Smokeless, due to the Spens ruling, presented some additions in the price range. L. & N. reports show that the motive power on this line is still in bad shape and the movement is slow.

CINCINNATI

Although there has been an ever-increasing offering of domestic coals the demand still exceeds the supply and there has been little price recession. However, the quotations have narrowed closer to 3-in. coal than for some time past. Only the smokeless prepared is out of line and this through the fact that there is little in the hands of the shippers and those with car numbers are holding it at a fancy figure.

There is little or no congestion in the yards of the connecting lines in Cincinnati nor at Portsmouth as it all depends upon the ability of the C. & O. to clear its lines on that there will be a clear western movement once more.

River business has again pulled up the total tonnage being delivered between Ashland and Louisville to a good figure. One Cincinnati firm with river connections is delivering splint lump at $3.75 in the city and $3 on the hill lines. Others are asking $3.50 for all-rail coal. Pocahontas lump quotations have been discontinued by one of the largest users while others are still quoting $4.50@$5.

LOW-VOLATILE FIELDS

New River and the Gulf

Matters have reached a point in the New River field where coal is being diverted from Western markets by frequent embargoes on all tonnage originating east of Handley. This has led the operators to go before the I. C. C. to obtain relief. Their position is that they are entitled to an equal proportion of Western shipments as compared with other districts on the C. & O. Embargoes have worked a hardship at a time when the Eastern market, particularly Tidewater, is overstocked.

Although there has been a slight improvement in transportation conditions in the Winding Gulf region production increases have been limited, with the mines producing less than 100,000 tons a week. The open market is rather flat as mines in this region are unable to ship to the West, where coal originates on the Virginian at least, owing to lack of interchange. For Tidewater, producers are not getting more than $3.50@$3.75.

Pocahontas and Tug River

Although Pocahontas production is being gradually increased, railroad disability losses alone are costing nearly 250,000 tons weekly. However, mines are able to divide their tonnage between Eastern and Western markets to a greater extent than some other low-volatile fields, at a time when the Eastern market is soft and when the piers are overstocked.

Although there has been a partial recovery from the slump in the Tug River field caused by almost a complete car famine, the mines are loading far less tonnage than was the case during either the coal or the rail strike. Production hinges entirely upon transportation conditions. Where it is possible, producers are shipping to Western markets because of a better price prevailing in that section.

HIGH-VOLATILE FIELDS

Kanawha

Kanawha mines are working just about one-fifth of the time and there does not appear to be any improvement in sight. Railroad fuel mines, in many instances, are being given preference. The car shortage with its resulting idleness is creating much dissatisfaction among the miners. Prices in the West for high-volatile exceed the Eastern market. Congestion has been making it difficult, however, to get coal through.

Northeastern Kentucky

With more cars available, the improvement has not been pronounced, and mines in the aggregate are not producing as much as 40 per cent of potential capacity which is scarcely sufficient to handle all contract orders. The railroads and public utilities are buying on a larger scale and there also appears to be a disposition among industrial customers in the West to loosen up a little.

Logan and Thacker

Less than a third of the normal output is being produced in the Logan region. Curtailed car supply has forced many mines into almost complete idleness. Western markets were somewhat better, with the result that there was a higher level of prices. Steam mine run averaged $3.75, with gas coals somewhat higher.

Owing to the car shortage the Kenova-Thacker mines are not producing more than 40 per cent of potential capacity or little over 100,000 tons a week. There has been a slight improvement in the situation, however, within the last two weeks. The limited production is not sufficient to meet the market requirements, for Western demand has increased. Most producers are able to handle contract orders only. So far as spot sales are concerned the ruling prices during the week ended Oct. 21 were $3.75@$4.

South

BIRMINGHAM

The situation in regard to car supply has grown more acute within the last week and is reflected in a slump in production. It is likely that the output will not go over 325,000 tons, a gradual decline having been noted for several weeks. Mines on the L. & N. and the Frisco have suffered, especially for lack of equipment.

Despite the difficult movement and the fact that there is little surplus supply for the spot trade, demand is not at all urgent and the amount of business being taken on is comparatively small. Consumers appear to be little interested beyond current requirements where contracts do not exist, but where fuel agreements are in effect there is an effort to expedite shipments and secure fuller compliance with contract deliveries.

The situation as regards domestic coal is one of much concern, as the output, measured to a great extent as it is by the demand for steam fuel, is far below the needs of the trade. The cool weather has rejuvenated to some extent the retail end of the market.

There has been no change in prices the past week, the minimum quotations on steam running 25c.@50c. under the fixed schedule, while maximum prices prevail for all domestic grades.

VIRGINIA

The output in southwest Virginia is ranging from 62 to 66 per cent and in some parts of the field, notably on the Southern, the output is as high as 84 per cent. Coke production too is on a larger scale. Contract orders are sufficient to absorb the greater part of the output so that there is really little spot coal available.

Canada

TORONTO

Cool weather has brought a rush of orders for anthracite which are being filled as far as possible from the limited supplies received, deliveries being restricted to one ton.

The demand for bituminous coal continues light and prices are variable, with quotations for 3-in. lump in carload lots f.o.b. destination, $8.75@$10.25. Pennsylvania smokeless is about $9 wholesale and $12 retail. The city has received further supplies of Welsh coal which is being distributed in small lots.

News Items From Field and Trade

ALABAMA

The Black Creek & Valley Coal Co. is the name of a new company organized in Jefferson County for the purpose of engaging in the mining and sale of coal. The officers are, E. C. Creel, president, O. J. Lynn and S. A. Latham, vice-presidents and J. M. Jerrell, Jr., secretary-treasurer. The capital stock is given at $100,000.

Properties known as the **Pawnee Land & Mineral Co.'s holdings**, situated in Blount County on and near the L. & N. comprising approximately 2,800 acres of timber and coal lands, are scheduled to be sold at Oneonta, Blount County, Nov. 15, 1922.

Under the direction of the federal fuel distributor, Lieut. E. P. Eldredge, of the United States Navy, has opened offices in Birmingham and is receiving from coal producers in Alabama daily reports of coal shipments on blanks which are provided. An effort will be made to induce operators to make shipments to nearby territory only or within the territory normally supplied from this field in order that equipment may be unloaded and returned for reloading as quickly as possible and thus relieve to some extent the acute car shortage now existing.

The suit of the state against the **Montevallo Mining Co.**, growing out of the bankruptcy proceedings of the early part of the year, which resulted from the breaking of the contract for the hire of state convicts, has been withdrawn by the state, as the coal company has paid up the amount due for hire of the convicts and is continuing the use of the state yards under a new agreement.

COLORADO

Development of the largest known continuous body of coal in the United States is the forecast to be inferred from the announcement that surveys have been completed for a railroad spur leading from Paonia to the properties of the **Gunnison Mountain Coal & Coke Co.**, on Minnesota Creek. A branch railroad of nine miles has been found feasible at a grade of 2.3 per cent. The line is to leave the North Fork branch of the D. & R. G. near the crossing over Minnesota Creek in the corner of the Paonia yards, and will follow that line to Lick Creek, where the coal will be mined and the new mining town established.

IDAHO

Towns around the Teton basin in this state have been suffering from the high price of coal to such a degree that they have turned their eyes upon the Teton mines as their immediate source of fuel. Many consumers in upper Snake river towns, such as Blackfoot, St. Anthony, Idaho Falls, Ferth, Shelley, Rexburg, Rigby, Tetonia, Driggs and Squirrel are making contracts with trucking concerns to haul their coal from the mines. Nearby consumers are doing it in their own wagons and trucks. This is giving the Teton basin a considerable coal boom.

ILLINOIS

Announcement has been made of the recent organizing of a new coal company which expects to sink a shaft near Dorrisville, Williamson County. The concern has incorporated under the name of the **Rhonnda Coal Co., Inc.**, with headquarters at Dorrisville. The following officers have been elected: President, Joe Pierson; vice-president, O. L. Turner; secretary, C. L. Rew, and treasurer, James Gray.

The O'Gara Coal Co., of Chicago, has reopened its No. 12 mine at Harrisburg. The mine was closed last April when the miners struck and has not been operated since that time. The mine is one of a dozen or more operated by the company in that district.

The mine of the **Kuhn Colliery Co.**, at Du Bois, Washington County, is now running full blast. The mine is now being operated for the first time in about 18 months.

A. P. Titus, general manager of the Chicago & Alton R.R., Bloomington, has resigned to accept the vice-presidency of the **Mason Coal Co.**, of Springfield and Chicago. Mr. Titus went to the C. & A. in 1912 as general superintendent. Since the road passed into the hands of receivers, he had been chief operating officer.

Three new mines were recently opened in Henry County. Now comes the report that experiment tests taken at the John Root farm, one mile northwest of Galva, disclosed a vein at a depth of 20 ft. Equipment will be installed at once.

The Rex Coal Co. has begun construction work on a 600-acre tract of land half a mile east of Warner, near the Orion and Coal Valley districts. The company has incorporated for $20,000. The first vein of coal was discovered at a depth of 28 ft. with a thickness of 26 ft.

The Central Illinois Public Service Co. has started the construction of the $6,000,000 power plant to furnish power to the mines in Jackson, Franklin, Perry, Williamson and Saline counties. Power distribution will begin in October, 1923. The main line will be to West Frankfort and will carry 133,000 volts. It will be a steam power plant, although on the Mississippi where future power may be secured from dams. Coal will come in via rail and river. This plant will displace several small ones in southern Illinois.

J. W. Byrne, formerly with the Sunnyside Coal Co., has been appointed on the sales force of the Brofer Coal & Mining Co., Chicago.

W. E. Rutledge, president of the Security Coal & Mining Co., Chicago, recently spent several days on a hunting expedition in Louisiana.

Coal mining companies in Cambria County have filed appeals with the county commissioners from the tri-ennial assessment on the grounds that the real estate was not assessed at the actual value thereof, being assessed without due regard to the valuation and assessment made of other similar properties in the country, but was assessed in excess of the value and assessment of such other properties. The following companies filed appeals: Holding of the **Wilmore Coal Co.**, Richland and Adams townships and Scalp Level borough and Conemaugh, Croyle and Stonycreek townships; **Berwind-White Coal Co.**, Richland and Adams townships and Scalp Level borough; **Maryland Coal Co.**, Richland, Croyle and Adams townships.

The Indiana & Illinois Coal Corporation has installed a generator at the mine at Kortkamp, which will furnish power for the operation. The estimated cost is $35,000.

The Service Fuel Co., of Kentucky, has filed incorporation papers in Springfield and will establish headquarters in Chicago. The capitalization is $100,000. J. I. Rodgers is president and J. B. Torbart, secretary.

INDIANA

A special judge in the Gibson Circuit Court at Princeton recently fined the **Oakland Coal Co.** $500 and costs for failing to obey a court order of May 22 restraining the coal company from pumping water from its wells on the land of Heber D. Wilson. The judge censured the coal company for its disregard of the court's instructions and said he was sorry the officers of the company had not been made defendants in the suit out of which the restraining order grew.

A codification of the mining laws of Indiana to be presented for passage at the next session of the general assembly, received tentative approval by the mineral codification commission at a recent meeting in the office of Clay Lattimore, state inspector of the state industrial board and chairman of the commission. The codification to be presented will arrange the mining laws of the state under several important headings, making all laws bearing on the same general subject embodied under the principal classification. The members of the commission at the meeting were John Hessler, president of District No. 11; William Mitch, secretary-treasurer of the district; William Johnson, Indianapolis, and Henry Adamson, Terre Haute, operators; Samuel Wilson and F. J. Wilton, deputy state mine inspectors.

The Deep Vein Coal Co. has purchased a plot of ground northwest of Princeton near the Evansville-Princeton traction line. On this ground the operating company intends sinking a shaft to open the old entries of the Princeton mine. The chief purpose of such a shaft, it is said, would be to recover valuable mining machinery which has been there since the cave-in last spring. The new shaft of the company, two and one-half miles south of Princeton, is down about 100 ft. and will be completed about Jan. 1.

IOWA

The Eldora Coal Co., of Eldora, has been incorporated with capital of $50,000. Herbert A. Huff is the president, H. J. Rees, vice-president, and W. E. Rathbone secretary-treasurer.

KENTUCKY

For perhaps the first time in coal history in Kentucky **western Kentucky operators invaded the eastern Kentucky selling field** when they secured [illegible] contracts at Lexington and Frankfort on coals of $1.75 for western Kentucky screenings. The freight rate from western Kentucky was about 40c. a ton higher, but the price is around $1.75 a ton lower than eastern Kentucky mine quotations.

It is reported that [illegible] in a sufficient rise in the Ohio River to permit a number of coal tows that were tied up or aground in the upper Ohio to move forward toward Cincinnati. These tows endeavored to get out on an artificial rise created by manipulation of locks and dams by federal engineers, but the rise failed.

Some real pressure upon Congress to get the **Ohio River navigation projects** put through will be exerted this winter by the **Ohio Valley Improvement Association**. It is calling attention to the fact that a decade ago the promise was made at Washington to start extensive work up and down the Ohio and it now asks that $20,000,000 be appropriated to complete the 9-ft. stage project that has been waiting for so long. The association at its October meeting in Louisville, re-elected Oscar F. Hatch president, W. P. Culkins secretary and George Puchta treasurer. They are all Cincinnati men. The executive committee is Edward Gibbs, chairman, Morris G. Freiberg, James A. Butler, A. K. Stites, Mr. Culkins, George F. Verkamp, Julian Tallack, Mr. Puchta and J. F. Hatfield. All of these men are from Cincinnati except Mr. Hatfield, who lives at Covington.

MICHIGAN

Under supervision of Charles F. Davis, fuel administrator for Wayne County, the **Detroit Coal Exchange** has sent out to coal dealers in the county the application blanks which they are required to fill out and sign preliminary to receiving the license provided for under the new fuel control law. The applications [illegible] to elicit information concerning the amount of fuel handled by the dealer last year, the proportion of it sold for domestic use, the quantity of [illegible] contracted to make sold for this year and the amount of each of these fuels that the dealer now has on hand. Some representatives of the coal trade in Detroit are predicting that the law will have the effect of preventing much of the state considerable coal that would otherwise have been sold there. Others, it is said, will anticipate their coal requirements where they do not need coal for heating or of other developments following the completion of mines.

H. H. Bloch Coal & Supply Co. has been incorporated at Muskegon, capital $[illegible].

MISSOURI

Evan Jones has been appointed superintendent of the Missouri mines at Moberly and has taken up that city his new duties.

Elmer W. Johnson, living near Quitman, has discovered a vein of coal on his farm and shafts will be taken at once to mine it. It is the largest and best vein of coal that has been found in this section.

Thomas L. Casey [illegible] **Quaker Ash Coal Co.** [illegible]

Sidney A. Capps has nearly [illegible] **Capital Coal & Coke Co.** [illegible]

M. E. Fight has been appointed [illegible] on the Hazard coal [illegible] **M. D. Jones** [illegible]

The St. Louis Coal Co. has filed articles [illegible] $15,000. The [illegible] Michael Joyce, Martin [illegible] Daniel T. Joyce.

NEW YORK

Director of Alfred D. Flinn as director of the Engineering Foundation, which is [illegible] industrial research [illegible] Charles F. Kettering, [illegible] Thomas A. Edison, chairman of the [illegible] Gano Dunn, president of the [illegible] Foundation is governed [illegible] Engineering Council, of [illegible] Societies which [illegible] Engineering Council, a committee which [illegible] Engineering Council [illegible] Flinn has been secretary [illegible] Foundation's activities [illegible] Engineering Foundation Board [illegible] Engineering Council [illegible] Flinn has been secretary [illegible] January 1914, and is widely known [illegible] engineering [illegible] The Engineering Foundation Board [illegible] Engineering Council [illegible] Engineering Foundation [illegible]

George W. Fleming, of New York, president of the Chicago Coal Corporation, [illegible] Kentucky, underwent a serious operation at the Veterans' Hospital in New York City on Oct. 21. Mrs. Fleming was notified [illegible] Fleming was operated upon, [illegible] pronounced out of danger [illegible]

The Seiler Coal Co., New York, is now selling the output of the **Pine Hill Coal Co.**, which recently purchased the property of the **Oak Hill Coal Co.**, serving it is mentioned with [illegible] of anthracite [illegible] Oak Hill Coal Co. [illegible] Seiler is now president of the Seiler Coal Co., Clarence D. Seiler, president of the Pine Hill Coal Co., vice-president, and H. E. Hilton, treasurer. H. E. Gibbs, who was with the Pine Hill Coal Co. and C. D. Seiler for [illegible] years, is now in charge of sales [illegible] the Seiler Coal Co. H. C. Lawrence has charge of Delaware sales; G. W. Yorio, Hudson and Wilton Corp. of Honesdale and Scranton [illegible]

Stockholders of the **Pennsylvania Coal and Coke Corporation** at a special meeting called for Dec. 14 will vote on a proposal [illegible] the outstanding capital stock from $1,000,000, consisting of 5[illegible] shares of [illegible] par value, to $17,000,000. Thomas H. Watkins, president, in a letter to stockholders, says that the proposed increase is recommended to make available additional funds [illegible] permanent [illegible] of the other companies [illegible] the action has been taken by the board [illegible] a stock dividend.

OHIO

Through a deal that has been [illegible] **Jewett, Bigelow & Brooks**, of Cleveland [illegible] the **Hulman Coal Co.** of Terre Haute, Ind., [illegible] by various mining properties in Knox County and Evansville, Ind. [illegible] Knox County [illegible] Jewett, Bigelow & Brooks [illegible] Hulman Coal Co. [illegible] Terre Haute, Ind., [illegible] Evansville, Ind.

TEXAS

A new wage scale, subject to ratification by miners and operators in Texas, has been negotiated and drafted at a joint meeting in Fort Worth. The agreement, if it is accepted by both sides, will continue operative until March 31, 1923. By that time it is expected the new national basic scale will have been agreed upon. Only 300 miners are affected by the agreement, it is said, most of them being at the mines of the **Bridgeport Coal Co.**

Henry Zweifel, United States attorney for the Western District of Texas, with headquarters at Fort Worth, has been conducting an investigation into the **alleged misconduct of Texas State Rangers toward striking coal miners** in the Mingus and Thurber mining districts of west Texas. Recently complaints alleging misconduct on the part of the state officers toward the miners were filed by John Wilkinson, district president of the U. M. W. An investigation was made by state officials, who reported that the charges were unfounded. Mr. Wilkinson then renewed his demand for federal investigation, and Mr. Zweifel was directed to make a full investigation. He is not yet ready to disclose the result of this investigation.

Distribution of coal supplies in Texas during the coming winter months will likely be taken in charge by the **Texas Railroad Commission,** as even a moderately severe winter will be certain to bring about a serious shortage, according to C. R. Goldman, of Dallas, secretary of the Retail Coal Dealers' Association of Texas. The members of the association, individually and as a unit, have offered their services to the railroad commission in the fuel situation, and have been accepted.

The Consumers' Coal Co. of San Antonio has recently been organized with a capital stock of $250,000. The company will conduct a general wholesale and retail coal dealers' business in San Antonio. Incorporators are: Joe Flory, J. T. Hall and A. L. Moon.

UTAH

The Democratic party declares it will repeal the Public Utilities Commission Act if its slate is elected this fall. The party suggests no legislation to take the place of the Act.

The state land office has denied the coal land lease application of **A. J. Mayes** at 10c. a ton royalty and offered the involved land—nearly 700 acres—at 12½c. royalty.

The coal deposit to be opened by the **Columbia Steel Co.** in Carbon County is being tested for its coking possibilities. The plans for building the new town are ready and various contracts are being let.

VIRGINIA

The Chesapeake & Ohio Ry.'s new steel coal pier at Newport News will be under construction next spring, according to plans at present. The structure will cost $2,604,000, and will be one unit of a development which will cost $16,000,000 on the entire system of this road. The construction of this pier will increase the dumping capacity of the Newport News terminals by from 500,000 to 750,000 tons per month. **The Virginian Railway** is expected to begin about the same time on the construction of a $3,000,000 steel coal pier to **supplement its Sewall's Point facilities,** while the **Norfolk & Western** is **electrifying its Piers 2 and 3,** and will be ready for operation, with 120-ton dumpers, in the spring. These improvements are expected to make Hampton Roads one of the largest coaling stations in the world.

WEST VIRGINIA

The J. L. Beury Estate, of Charleston, has been incorporated with an authorized capital stock of $225,000. This estate has large coal holdings in the New River field where the late J. L. Beury was one of the pioneer operators. Under the terms of the articles of incorporation the estate is permitted to mine coal and to hold real estate, mineral lands, etc. The incorporators are R. T. Hubbard, F. N. Bacon, B. E. Baker, A. B. Abbott and T. H. Mahood, all of Fayetteville.

Further development of Monongalia County coal lands is presaged by the organization of the **Two States Coal Co.,** with headquarters at Morgantown. This enterprise is capitalized at $50,000 and the leading figures in the new concern are John E. Blaker, A. C. Lee, M. E. Lee, of Morgantown; C. S. Riggs and L. A. Riggs of Fairmont.

Owing to the fact that **William Barrick** has been appointed manager of several coal operations in Logan County, he has withdrawn as one of the Republican candidates for the legislature of West Virginia from McDowell County.

John M. Wolfe, formerly general superintendent of the Jamison Coal & Coke Co., in West Virginia, but now representative of the Operators' Fuel Agency, in Philadelphia, was a recent visitor in the Fairmont region.

George B. Taylor, general manager of the Jamison Coal & Coke Co., with headquarters at Greensburg, Pa., was a recent visitor in Fairmont inspecting the Marion County plants of the company.

Major W. P. Tams, of Tams, and **George Wolfe,** secretary of the Winding Gulf Operators' Association, are two members of a committee named by smokeless operators to present the details connected with the operation of smokeless mines to the new fact-finding commission recently created by Congress. **W. D. Ord,** of Landgraf, president of the Empire Coal & Coke Co., is chairman of the committee.

At the opening of the trial of C. Frank Keeney, president of District 17, U. M. W., in Charles Town on Oct. 23, under an indictment charging him with being an accessory before the fact in the killing of Deputy Sheriff George Munsey, of Logan County, during the armed march of 1921, T. C. Townsend, chief counsel for the president of the district mine workers' organization, entered a demand to know who was representing the state and at the same time made the charge that previous prosecutions had been financed by the Logan operators' association. He contended that a conspiracy existed to crush unionism in the state. Replying to Mr. Townsend, Colonel F. W. Brown told the court that he and three other attorneys in addition to Lon Challin, prosecuting attorney of Logan County, represented the state.

The trial of George Barrett, international board member of District 29, U. M. W., indicted about six weeks ago along with Lawrence "Peggy" Dwyer, also a board member of District 29, and Davis Robb, an international organizer for the union, by a grand jury in Fayette County, on the charge of "counseling, hiring and commanding parties to steal and conceal a machine gun taken from the railroad station at Pax, in August, 1920, and counseling and aiding in the disorders prevailing at Willis Branch," was begun in the circuit court of Pocahontas County before Judge S. H. Sharp on Oct 17. The disorders at Willis Branch grew out of the refusal of William McKell and associates, owners of the property, to sign an agreement with the union. The place was literally shot off the map by union miners.

It is generally reported in the New River field that **Henry Ford,** who recently abandoned his **Nuttallburg mine,** is willing to part with that property, and that the **Maryland New River Co.,** which has several operations in the same section, is negotiating for a lease on the Nuttallburg property, having in mind the operation of the mine from the Keeney's Creek opening.

In view of the fact that there were **11 fatal mine accidents in the state during September,** R. M. Lambie, chief of the department of mines of West Virginia, in an effort to minimize the danger attendant upon the mining of coal and reduce the number of accidents has called attention of operators, mine officials and employees to the large number of accidents and has said: "I want you to carefully read the accident report; analyze it carefully and you will note that the majority of these accidents could have been prevented had the proper precautions been taken. The killing of so many men in and about the mines and the crippling of many more is a most lamentable thing as preventable accidents are not only a liability to the mining industry but are also an appalling loss to the state. The mine officials must see that every precaution is taken to prevent accidents. The most rigid discipline must be enforced and employees, officials and operators are asked to co-operate with us in getting rid of the chance taker, as he not only endangers his own life but also the lives of his fellow workmen."

C. C. Beury, head of the Beechwood and other coal companies operating in the New River field, has returned from a trip to Atlantic City.

W. D. Ord, head of the Empire Coal & Coke Co., with headquarters at Landgraf, was a recent visitor in Washington, D. C.

The Baltimore & Ohio has acquired the **Indian Run & Northern Railroad** from the **New England Fuel & Transportation Co.,** paying $[illegible] and giving its obligations for the balance of $[illegible]. This road is the Logan tract of 11 miles which was severed from the Elkins system a few years ago.

The West Virginia Gas Coal Co. has perfected its organization with the election of Daniel Howard of Clarksburg as president; P. J. Reid as vice-president, J. B. Wyatt as secretary, D. T. Quinn as treasurer and J. Howard Henderson as general manager. The company is capitalized at $700,000. The company controls about 3,300 acres of high grade Pittsburg coal and about 50 acres of land in fee in Cedar Creek in Otter District, Braxton County. Development work will be begun within a few weeks.

WISCONSIN

The first car of coal for the Brotherhood of Locomotive Engineers at Baraboo arrived at that place recently and was distributed among the membership of that order. The brotherhood owns extensive coal fields in Virginia, from which it will be able to supply its members with coal. All surplus will be sold to friends of engineers at cost.

CANADA

BRITISH COLUMBIA COAL OUTPUT DURING SEPTEMBER, 1922

Vancouver Island District

Mine	Net Tons
Western Fuel Corp., Nanaimo	67,122
Canadian Collieries, Comox	39,495
Canadian Collieries, Extension	15,823
Canadian Collieries, South Wellington	6,406
Granby Cons. M.S.&P. Co., Cassidy	21,135

Total	74,924
Total, all districts	267,350

Operations at the **Dominion Coal Co.'s** coal pocket at St. John, N. B., were [illegible] heavier than at present. The force of employees has been doubled in the past few weeks. One steamer per week is arriving with bituminous coal.

The city council of St. John, N. B., has let off the purchase of coal for the city hall, water and sewerage building, police station and court building, etc., during the summer and now finds itself in the plight of being unable to get hard coal at all.

Colwell Coal Co. of St. John, N. B., is preparing for an active winter and spring. The winter port steamers to St. John and Halifax will start about the middle of November when navigation on the St. Lawrence ceases and extends until the middle of April and first of May, when navigation reopens.

It is estimated that the **coal resources of British Columbia** [illegible] This includes actual reserves containing 23,831,242,000 metric tons and a probable reserve of approximately [illegible] metric tons. These figures were compiled recently with a view to arriving at some conception of the value of the natural resources of the province. The Nanaimo district is a new [illegible] opened on Gulf Navigation Co. and which made its first shipments last August. It is anticipated [illegible] product for two mines in the Kootenay Valley by Williams Coast [illegible] tions. Vancouver City [illegible]

WASHINGTON, D. C.

The personnel of the committee of anthracite operators who met the U. S. Coal Commission [illegible] week is as follows: [illegible] Committee of Anthracite Operators: E. H. Williams, W. J. Williams & Peters, New York City; W. J. Richards, president Pennsylvania & Reading Coal & Iron Co., Philadelphia; E. H. Williams, member executive committee of the Hudson Coal Co., New York City; W. J. Richards, president Lackawanna & Lehigh Coal & Iron Co., Scranton; A. B. Wenzell, Coal Exchange, New York City; A. B. Jessup, vice-president Jessup-Moorehead Coal Co., Philadelphia; C. Harrison Conyngham, Lehigh Coal & Navigation Co., Philadelphia.

Federal Fuel Control Notes

H. C. Belt, former freight traffic manager of the [illegible], recently designated as an assistant to the federal fuel distributor, will give [illegible] to the matter of coal supplies for the public utility companies. Information [illegible] as to lack of coal, lack of cars and lack of transportation service will be given consideration by Mr. Belt, who will also keep in close touch with [illegible] embargoes and recommendations issued by the Car Service Division of the American Railway Association to suppress [illegible] interchange or movement of equipment.

Federal Fuel Distributor Spens was in [illegible] for a **conference with the operators of central Pennsylvania** and made it plain that the domestic consumer of coal must receive his fuel supply at reasonable prices commensurate with [illegible] conditions. Among the operators present were: William Wetter, Philipsburg; Charles Maxwell, Morrisdale; J. S. Somerville, Cedarsdale; Thomas Kelly, Irvona, and Harry Scott, of Philipsburg. Secretary Charles O'Neill and W. A. Jones, statistician of the association, were also present.

Mr. Spens pointed out that because of the [illegible] of prices in the central Pennsylvania field, there is little need for specific attention in that respect at this time. In the exercise of his authority, Mr. Spens pointed out that he may direct a re-routing of cars so that if there is a congestion on one route, the coal may be sent over another road. In this way and by other means within the scope of the act he will aid in the providing of cars where they are most needed.

At a conference held with the Federal Fuel Distributor in Washington, members of **a committee of the National Coal Association**, of which J. C. Brydon, of Baltimore, is chairman, outlined the present transportation needs of the different bituminous-coal producing districts of the country. Fuel Distributor Spens assured the committee that remedial measures would be given the earliest consideration.

A. L. Humphrey, president of the Westinghouse Air Brake Co., Pittsburgh, has been appointed as a member of the advisory committee named by the federal fuel distributor to represent American industries in the present fuel emergency.

Lieutenant Commander E. A. Cobey, U.S.N., has jurisdiction over the district representatives of the federal fuel distributor stationed in the different bituminous coal fields. **C. J. Hepburn**, of Philadelphia, recently appointed general counsel, will give consideration to all legal matters. **Wayne P. Ellis** in addition to general statistical work, will give attention to the movement of coal in the upper Great Lakes region.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 22 NEW YORK, THURSDAY, NOVEMBER 9, 1922 Number 19

Car Shortage and Costs

IRREGULAR operation of coal mines, from whatever cause, increases costs of production. Lack of orders at times is the main cause for irregular daily operation; today it is lack of railroad cars in which to load the coal. Proper distribution of cars will do much to lessen the cost of operation even on short turns.

In the East it is the general practice of the railroads to seek a daily distribution of a short car supply equally among the mines served. If the cars available on a given division are sufficient to satisfy but half of the orders for cars, then the car distributor seeks to give to each mine one-half its rating. Quite often the supply of empties comes in small lots; a few may have been shunted in late the night before and throughout the morning additional cars be spotted. The mine superintendent seldom knows when he starts with the few cars whether or not more will be forthcoming. He must keep his men on the job if there is any expectation that more cars will come, for if he shuts down and fails to load such cars as are put in later in the day, these cars are counted against his allotment twice—once for the day delivered and again the next day.

This daily uncertainty plays hob with costs. During the waits for cars the main haulageways become choked with loaded trips. The tipple men stand around with nothing to do. The whole force draws pay with no work to do.

In some of the Middle Western fields the operators and railroad officials long ago got together to remove this irritating and unnecessary trouble. They agreed that the best interests of both parties were served when a mine was supplied with cars for a full day's operation. Accordingly when the car supply was sufficient for but, say, two days per week, the mines would be served in turn with a full run of cars for two days each week, and would stand idle the other four days. The superintendent thus is able to tell the men in advance when the mine will run and the men know that when they turn out they will get a full day's work. Inequalities arising in the distribution are equalized each month, so that each mine knows that it got its full share of the cars supplied the district. When the mine is going all are busy, not sitting around part of the time wondering whether more cars will appear.

The compelling reason for this development in parts of Illinois and Indiana, for instance, is not present in the East. In this Western territory the mine workers for the most part live in towns at a distance from the mines and ride to work on trains. They long ago rebelled at the early rising and trip from town to mine only to find no work or but part of a day's employment. In the East the mine workers for the most part live in close proximity to the mine and suffer only the early rising should there be no cars and easily make their way home when the supply fails. But the operator has relatively higher payroll cost in the East than in the West because of the difference in practice. Why can't the Eastern operators get together with their railroads on such a basis for car distribution and save themselves money and their mine organizations much trouble?

The Value of Time

IN ANCIENT Rome no paid or voluntary fire force kept guard over the city. Every man waited till he had a fire; then he organized his own force—himself, his wife, his family, his slaves (if he had any), the passing mechanic or the expectant beggar. Now it happened that Crassus noted this defect and sought to make money from the remedying of it. Note this from the historical author Charles Oman:

> Still more astonishing was his amateur fire brigade and the way in which he used it. He got together a body of five hundred workmen—carpenters, masons and the like—provided them with ropes, buckets, ladders and tools. Whenever there was a fire (and fires were as common as they were dangerous in the crowded city) he went down at the head of his gang and called on householders whose property was in the immediate neighborhood of the conflagration. He then offered to buy their houses as they stood at a very low figure. If the terrified owner consented the fire brigade was turned on and the mansion generally preserved. If he refused, Crassus went away with his men and let the fire do its worst.

A bad bargain when every minute meant immense loss, yet is it not true that many a bargain is made today under a like stress even where it is not felt, especially by the purchasing agent who is making it? Many a mine foreman in a large company, seeing a clear profit in a new piece of machinery, is obliged to wait while the requisition is held up by the indifference of the chiefs above him and then finds that the purchasing agent delays the placing of the order in the hope that by shopping around he may be able to show a saving of a few dollars. Meanwhile the cost is mounting around the mines, archaic methods are demanding their toll of unnecessary expense, the output is being restricted and the uncompleted work is jeopardizing life. The change proposed must be made, and the sooner the better—the sooner the machinery is installed, the more loss will be avoided. The old Roman who disputed coin with Crassus when his house was burning was little more foolish than the modern American who disputes dollars while the losses from inefficient labor, reduced output and danger are piling up.

Prudence in buying, a little shopping around, if done diligently, may be excused, but due care should be taken lest the loss by delay exceed many times the gain to be attained by circumspection and even many times the whole investment to be made. A tendency among purchasing agents is to hurry orders for replacements, rightly believing that such re-establishment materials are indispensable, but often a new piece of machinery that will afford economies in operation is of equal or even greater importance.

Are Income Tax Returns Significant in Company Profit?

Commission and the engineers' committee of the Fuel Administration found considerable difficulty with the two accounts mentioned and it is understood that an arbitrary allowance of several cents per ton was made by the latter for contingencies.

The form of report adopted for 1918 took maintenance and repairs of structures and equipment out of the detailed operating classification and set up separate figures for them. Miscellaneous profits or losses incident to operation of the mines also were taken out of the schedule of miscellaneous income and made debits or credits to cost. With these exceptions the results obtained were, generally speaking, comparable with the 1917 figures.

The Federal Trade Commission attempted a very elaborate form for 1919 costs in which it was sought to make separation as between operation and maintenance throughout the operating schedules. The commission was never able to put this form into effect because of lack of appropriation and lack of support of the Fuel Administration.

They revamped their scheme of cost forms for 1920 and sought to provide for inclusion in labor cost under maintenance and repairs of the repairs on miners' houses, which had theretofore been carried as a debit to the rent account and the net result shown as a miscellaneous profit or loss. Supplies were handled in the same manner. They also contended that the value of the coal produced at the operation and used under the boilers should be excluded from power costs.

The tendency of the Trade Commission thus has been away from the general policy of the Treasury. The differences were pronounced and eventually caused the split between the National Coal Association and the commission. The Treasury permits such charges as do not materially increase the production to be deducted as expense. The Trade Commission, where the items could be identified, is understood to have eliminated them or to have spread the charges over a period sufficiently long as to not distort the general average. Doubtless many such items were of necessity passed without change, because of the impossibility of positive identification.

The Treasury Department permits the depletion charge to be based on March 1, 1913, valuation. The Federal Trade Commission provided that such charges must be made on the basis of cost. The same rule would naturally apply to the amortization of the value of leases.

In the case of depreciation, the same differences of application would necessarily follow. The instructions of the Trade Commission were to the effect that plant and equipment were to be depreciated at a rate per cent, and did not countenance deduction on the basis of depletion or a rate per ton, while the Treasury Department allows either method at the option of the taxpayer, and in addition the deduction of composite depletion and depreciation, if the taxpayer so elects. The cost of fuel is permitted by the Treasury Department. The later forms of the Trade Commission do not permit its inclusion in cost.

The 1920 forms of the commission instructed that the cost to the present owner of development of the main tunnel, shaft, slope or drift plus the estimated future cost of such work should be amortized pro rata with the exhaustion of the coal recoverable through such development. The Treasury Department does not permit the deduction of *prospective costs.*

Work Longwall by Machine Loaders as Long as Roof Will Stand, Then Shift to More Costly Room-and-Pillar Plan

Speedy Extraction of Coal Will Increase Safe Working Span—Goaf Is Not Expected to Fall Till Weakened Further by Room-and-Pillar Mining—Loader Works Its Way Under Shot Coal Face

By M. R. Martin*
Huntington, W. Va.

BECAUSE room-and-pillar mining is the form of operation most in use in America, the thought and efforts of designers of underground-loading machinery have been directed toward perfecting a machine that will operate successfully and economically in a mine thus laid out. Experience has proved that the success of, and economy in, machine loading hinges directly on the car supply to the loader, and unless a machine is given many more than a miner's turn of cars, it cannot and will not be a success.

In room work, unless the face is turned on an angle of, say, 45 deg. (the degree of the angle may, of course, be greater or less), only one car at a time can be supplied to the loader, which means that while the load is being taken away and an empty is being supplied the machine must be shut down. The manner in which this is accomplished, whether by motor, mule or man power, would be an item of expense that would detract considerably from the saving made by machine loading. Another item of expense involved is the time lost in "flitting" the machine from one narrow place to another.

Why Longwall Has Often Been a Failure

To obviate these and other objections inherent in the loading of cars at one end some method must be adopted that will provide a long working face, so that the machine can be supplied uninterruptedly with cars. Longwall, where it has been attempted in this country over any large area, has not been successful for the reason that we cannot bring ourselves to the painstaking and, as we view it, expensive methods of building packwalls behind the working face to protect the overlying strata. The use of posts or timber chocks does not serve the purpose sufficiently well, and the result is that longwall working in the regular sense has proved unsuccessful. It might be added that uncertain labor conditions have had as much to do with the failure as any other one cause. Machinery, of course, will reduce that difficulty considerably.

Longwall, or block mining, in the United States, where packwalls or gob stowage are not used, has followed two general lines. One method is to form blocks and commence the mining either inward or outward on one side of the block, proceeding until from 10 to 25 per cent of the block remains. This much is left for protection, because if it were mined out in its entirety

FIG. 1—VIEW FROM COAL-FACE END OF LOADER

*Vice-president and general manager Atkinson Car Loading Machine Corporation.

Note—Headpiece shows side view of Atkinson car loader with the loading bar on the left. The conveyor has disappeared. When the loading bar revolves the bits on its periphery lift the coal onto the conveyor.

and the work continued to the next block, the distance between the two supports of the beam would be so great that the weight of the roof would break it down.

Once broken it would be impossible to regain the face or side without driving another entry through the solid coal providing a pillar large enough to support the overlying strata at one end of another beam. The other method is to mine on the end of blocks that lie parallel with the entry, proceeding to a definite point, stopping, and picking up the mining on another end, leaving a block of coal to support the end of the beam away from which the mining is being carried on. Lack of recognition of these principles has been the cause of many failures in block or modified longwall mining. Either of the two methods just mentioned may and should be criticised severely because with them much coal is lost.

In certain sections of West Virginia the method of mining adopted must be such as will convince the lessor of the coal land that as much coal as possible will be recovered. And when such land-owning companies can show that from 90 to 95 per cent of their workable seams are being recovered by their approved room-and-pillar methods, it is not likely that they will consent to a change in the system of mining until convinced that the same high percentage of recovery can be obtained by the system replacing it. It also is true that where the lessee is exacting in his requirements as to the

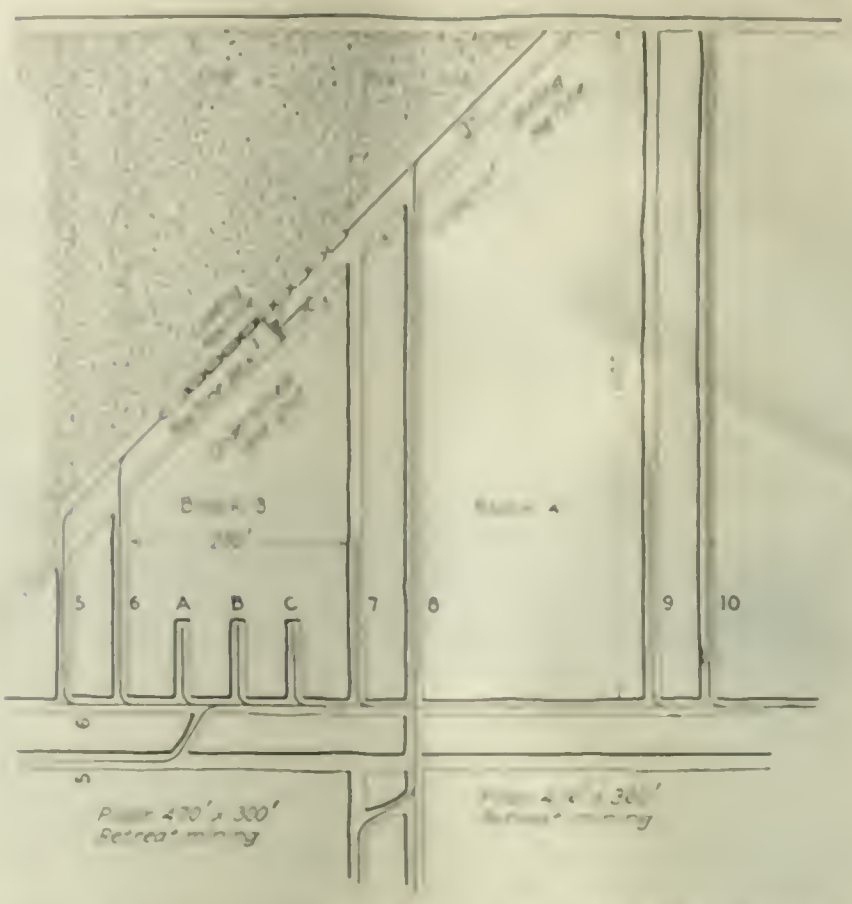

FIG. 2—DETAIL OF LONGWALL AND ROOM WORKING

As the triangular area gets to have a span which, with the particular roof and overburden, may be regarded as approaching a limit, the longwall face is abandoned and the work of drawing the blocks is pursued from rooms where there is less opportunity for rapid, cheap and effective operation.

method followed, the result is better and more economical mining.

The plan† of mining outlined in Fig. 3 is believed such as will assure as high a recovery as, if not higher than, can be obtained by room-and-pillar methods. Vary-

†This plan of mining was designed and description given me by P. A. Grady, general superintendent of the A. J. King group of mines, Huntington, W. Va.

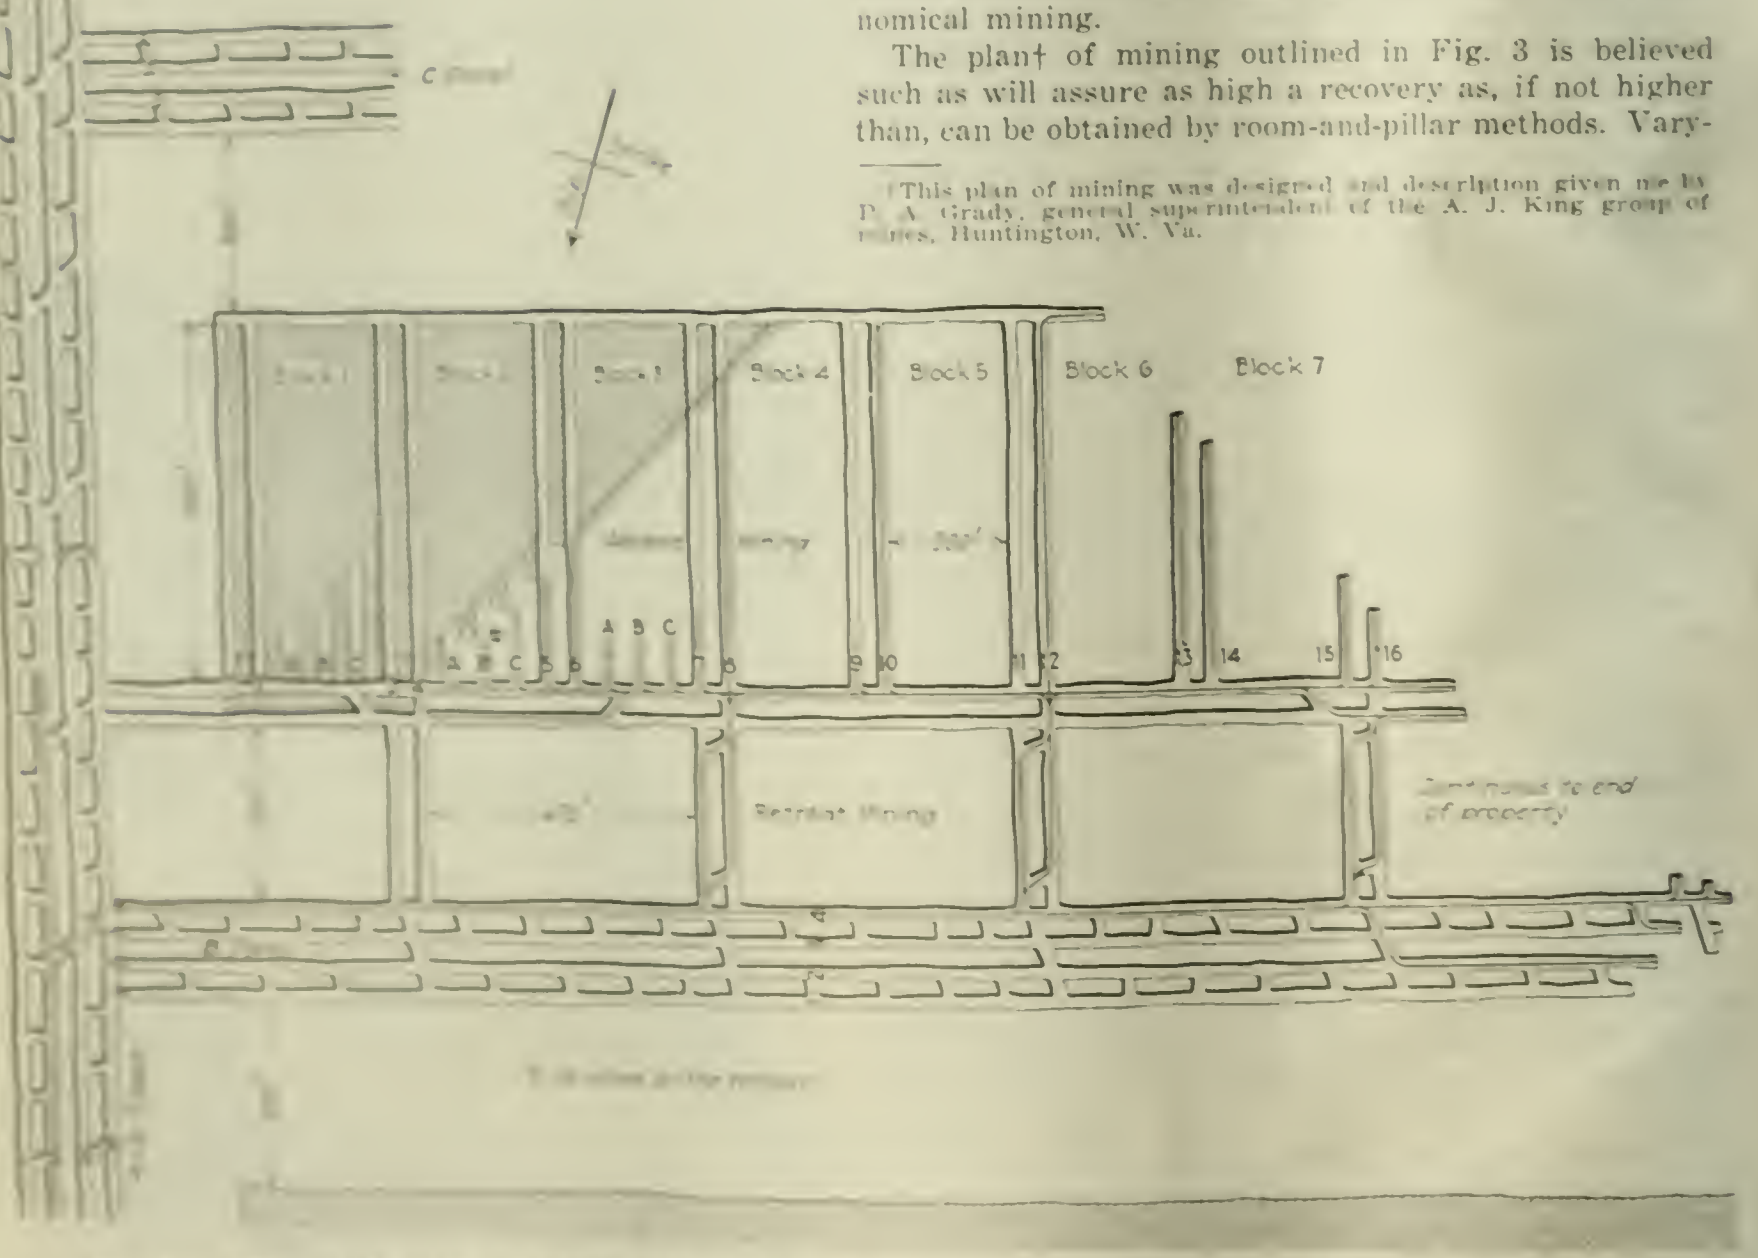

FIG. 3—METHOD OF WORKING WHOSE ROOF IS GOOD AND LARGE AREAS CAN BE MINED WITHOUT CAVING

As fast as the room ends reach limits of the property, coal is taken out by retreating longwall and without packwalling or the building of chutes. Speed in operating is called for to increase distance over which this can be done. As room ends reach limits of the property, coal may be extracted. But longwall is abandoned and rooms are driven in the old fields, and coal is recovered by room-and-pillar methods.

ing conditions may determine the length and width of the blocks as well as the pillars, though the greater the length, the larger the production and degree of concentration attainable.

For explanatory purposes the driving of entries and rooms to form the blocks will be called the first mining. Just as soon as the first block is formed mining can be started to draw it back. This will be termed the second mining. The angle at which this mining is done is a matter of choice and conditions. An angle of 30 deg. will provide a much longer working face than will an angle of 45 deg., as shown in Figs. 2 and 3.

The distance that mining can be carried on the end of the blocks is unknown. However, mining men who have had much experience mining a longwall face away from a barrier pillar, as is done in this instance, where the roof becomes a supported beam with one end resting on a barrier pillar, the other on the end of the adjoining block, know that it is possible to draw the block a long distance before the first great fall takes place. It is a well-known fact that if a large number of men are put to work on a face of this length, the retreat will be quite rapid and the work can proceed a great distance before the roof makes its first break. By reason of this fact we know that through the use of mechanical loaders it is entirely possible to extract the whole block so rapidly that the roof does not have time to break down until it is entirely worked out. To accomplish this some timbering must be done, though, for obvious reasons, this is not shown in the drawings. If after taking the face back a certain distance it is found that the roof will break, making it difficult to maintain the long face, the remaining coal can be obtained by driving rooms as indicated by dotted lines, drawing the pillars as in ordinary room-and-pillar work advancing. This is called the third mining and it need be used only where the longwall face can be maintained for only a limited distance away from the barrier pillar.

The track arrangement as shown provides for a continuous advance of the block sections. The room switches have to be reversed before the second mining of any block. At the mouths of rooms Nos. 9 and 10 the switches are already turned and are waiting for the longwall to reach them. From room No. 12 is shown the track layout for the first mining of rooms and entries. Much sidetrack is shown in the haulway rooms from the main entry or *B*-panel entry, and at no great distance from the producing faces. This *B*-panel entry, once started, is continuous to the end of the property, and once the development has reached the point shown the maximum production can be maintained during the entire life of the mine, as only one-half of the coal is taken out on the advance, the other half to be recovered by the same method on the retreat. In laying out a new mine on this plan, it would be well to have the main entries removed far enough to the right of the property to permit a certain quantity of coal on the left to be recovered by room-and-pillar methods, until the coal

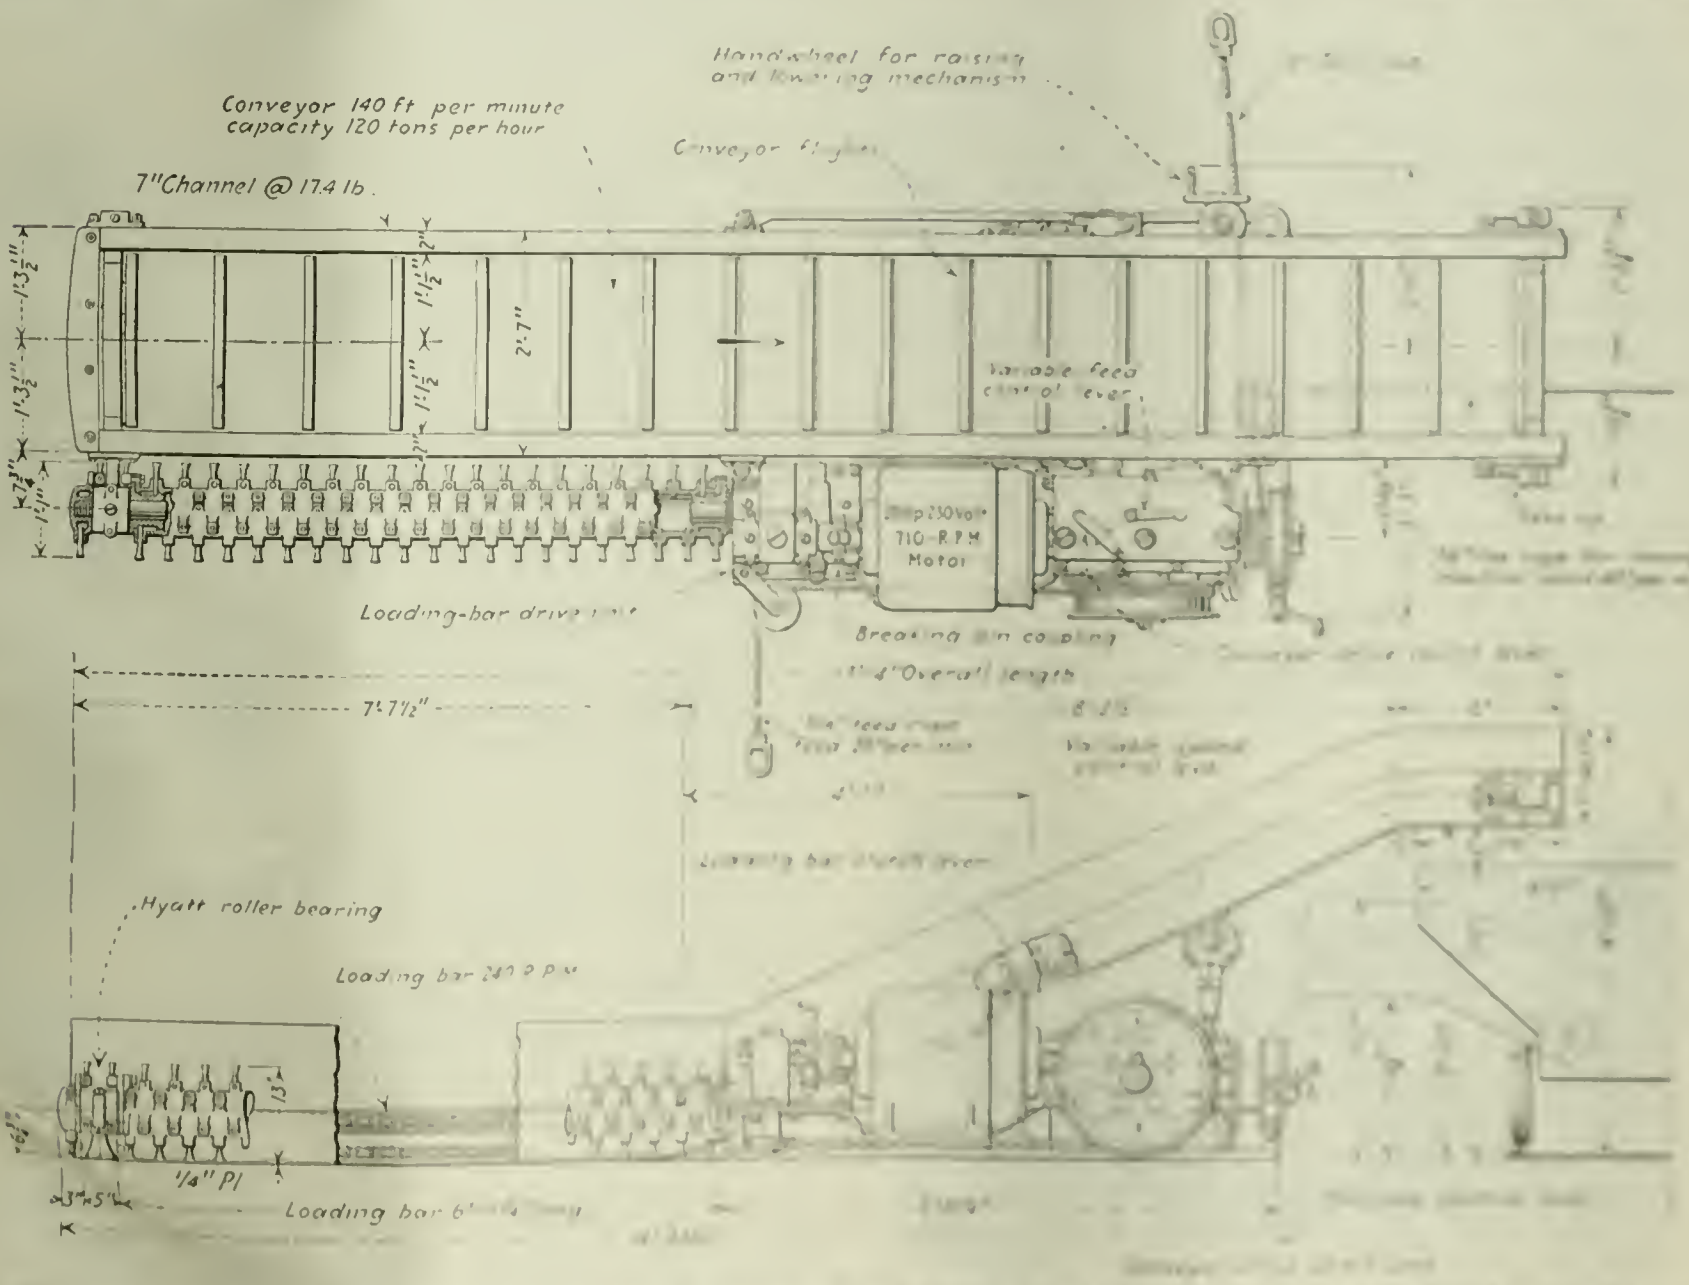

FIG. 4—PLAN AND ELEVATION OF LOADER AT WORK AT BUFFALO EAGLE COLLIERY

On the right can be seen the position the machine would assume in loading another conveyor extending along the face, the upper surface of the machine conveyor being at its highest point 29½ in. above the floor of the mine.

on the right has been sufficiently provided with entries and rooms for its development in accordance with the outlined plan.

Reference to Fig. 2 shows an enlargement of blocks Nos. 3 and 4 and the method by which a loading machine is being worked on this plan. This drawing also shows the intense concentration possible under this plan of working. This machine is shown in the headpiece and Figs. 1, 4 and 6.

It operates on the principle of a shortwall mining machine, being propelled along the face in the same manner. It is equipped with a drum, which winds a wire rope the loose end of which is secured by a machine jack set against the floor and roof of the mine.

Coal Is Lifted by Bar Onto Conveyor

Instead of the flat cutter bar used on an undercutting machine a round bar 7½ ft. long has been substituted. Chisel-point mining-machine bits have been set in the periphery of the bar, and this bar, rotating at a speed of 200 r.p.m., lifts the coal onto the conveyor, which runs parallel to it. The bar also does the bottom scraping, which ordinarily must be done by hand. One who has not seen the machine operate probably would assume that this bar, revolving as it does at a high speed, would grind and break up the coal, but the only real tearing action is in bottom scraping, for in reality the bar comes in contact with only a small portion of the coal loaded, most of it falling onto the conveyor, by virtue of the fact that the machine undermines the coal.

The best way of shooting the coal for loading by this machine is to use only half of the normal charge. This leaves the coal in a tight or standing shot, saving in the cost of shooting and increasing the percentage of lump coal. This machine will deliver coal to suit the height of the mine car. Where face conveyors are used the height of the motor on the machine will be the determining factor. A drop-front truck is provided, the machine loading and unloading under its own power. The truck is not self-propelled, however, but has to be drawn by a locomotive whenever it is necessary to move it from one place to another. Such transfers do not often have to be made when a system such as the one just described is used. The conveyor has a rated capacity of 120 tons per hour. The actual capacity, of course, is determined by the speed at which the machine is fed into the coal, the height of the seam, and the depth of the undercut.

FIG. 6.—OBLIQUE VIEW FROM UNDERSIDE SHOWING

An actual stop-watch test made by disinterested parties at the mine of the Buffalo Eagle Colliery Co., Braeholm, W. Va., gave the following results:

Test of Loading Machine at Braeholm, W. Va.

Number of cars loaded in test	20
Level full capacity of cars, tons	2.75
Height of coal, feet	6½
Depth of undercut, feet	6
Time required to load 20 cars	31 min. 40 sec.
Time out setting jack	1 min. 40 sec.
Average time per car	1 min. 30 sec.

Conditions for this test were much the same as shown in Fig. 5; a motor was in constant attendance pulling the cars past the loading machine. Three men operated it, one man controlling the movement of the machine, another breaking down any coal that adhered to the roof (caused by small binder in the coal), and the third man topping off the cars. This machine is manufactured by the American Coal Loading Machine Corporation, of Huntington, W. Va.

Mine Officials Should Keep Abreast of Up-to-Date Safety Practices.—The safety of coal mines and miners cannot be assured if the men in charge are not familiar with safe methods. The following recommendations, therefore, are offered by the U. S. Bureau of Mines:

(1) All persons in responsible charge of the direct operation of coal mines—including superintendents, foremen, firebosses and shotfirers—should be required to have certificates of competency issued by the state, showing that the applicant has passed an examination clearly establishing his knowledge of what constitutes up-to-date safe practices in the branch or branches of mine operations under his jurisdiction. All such certificates should be revocable by the state for cause, should expire after five years, and should be renewed only upon taking another examination. The latter requirement would compel all operating mining men to keep conversant with progressive safety practices.

(2) Mining companies should require superintendents, foremen, firebosses and shotfirers to keep thoroughly familiar with requirements of state laws, as well as with up-to-date practices in regard to ventilation, dust, electricity in mines and explosives. If possible, this information should be conveyed by lecturers or specialists conversant with the best current practices, otherwise the companies should provide for sending current mining literature to its mine officials.

(3) Each mine should make a special study of its gas and dust condition. It might be advisable to enlist the services of the U. S. Bureau of Mines, whose coal-mining division has made and is making extensive studies as to the prevention of explosions in coal mines.

At the Pittsburgh (Pa.) experiment station of the U. S. Bureau of Mines a complete study is being made of the Burrell gas indicator as applied to the analysis of air mixed with methane, hydrogen and gasoline vapors. Both the theory on which its operation is based and its practical uses are being considered and a few improvements will be recommended.

Power Used at Twelve Collieries and Its Distribution For Eight Separate Operating Purposes

Company Uses Watt-Hour Meters to Determine Power Consumed for Each Purpose at All Collieries—Haulage Is Largest Item—Breaker and Compressed-Air Machinery Where Installed, Are Leading Current Cosumers

By G. M. Kennedy*
Lansford, Pa.

As HAS often been stated, it is rather difficult to take the total steam-power cost and distribute it with any degree of accuracy among the various engines in the plant, whereas by means of the watt-hour meter an accurate record can be kept of the electrical power consumed by each motor or group of motors.

Realizing some years ago that many advantages were to be obtained by the use of watt-hour meters one of the engineers of a large anthracite company decided to order them as part of the electric equipment to be installed at the several mines. In consequence all the electrical installations of the company are well equipped with watt-hour meters. It must not be assumed from this that each unit of electrical apparatus was purchased with a watt-hour meter as if it were an integral part of the unit, but the various groups of electrical equipment, as will be defined later, were supplied with this integrating device. The cost of a watt-hour meter is insignificant as compared with the cost of the equipment with which it is to be used, and its purchase is, therefore, entirely justifiable.

The method of grouping the apparatus for power measurement is quite flexible and depends much on the method of accounting adopted as well as on the individual opinion of the person in charge of the equipment.

However, one satisfactory method for dividing the power consumed into groups, and it is that which has been introduced at the twelve plants described in this article, is as follows:

(1) Transportation, or Haulage	(5) Lighting
(2) Breaker Machinery	(6) Hoisting
(3) Ventilation	(7) Compressed-Air
(4) Drainage	(8) Charging Stations

The order in which they are arranged is immaterial.

For the past twelve years records have been kept of the tons prepared per month, here marked "tonnage," and the kilowatt-hours consumed per month arranged according to the headings given above. These records cover ten collieries designated in the following tabulations as *A*, *B*, *C*, *D*, *E*, *F*, *G*, *H*, *J* and *K*, also two washeries as *L* and *M*. The tabulations are taken from an average month in the year just past.

Item I shows the power used in the haulage of ten collieries and, of course, all hauling done during the month is recorded, including all work on which the electrical locomotives were used. The variations in the kilowatt-hours consumed per ton at the various collieries is accounted for in the differences in the gradients, in the lengths of haul, in the yields per car, etc.

Item II shows the power used in the preparation of the coal and includes the power consumed at night time, on Sundays and holidays in making repairs to machinery. The washery designated as *M* in this table shows a high number of kilowatt-hours per ton because much

CONSUMPTION OF POWER AT TEN COLLIERIES AND TWO WASHERIES DISTRIBUTED BY EIGHT PURPOSES FOR WHICH IT IS USED

Item I—Haulage

Colliery	Tonnage	Kw.-Hr.	Kw.-Hr. Per Ton
A	51,232.15	174,100	3.3982
B	39,600.01	60,040	1.5161
C	17,050.02	58,900	3.4546
D	20,456.12	68,000	3.3241
E	24,689.12	41,020	1.6614
F	36,475.05	62,780	1.7211
G	35,301.16	77,300	2.1897
H	31,851.11	49,190	1.5443
J	38,805.00	61,700	1.5900
K	6,424.13	11,990	1.8679
	301,887.07	665,020	2.2022

Item II—Breaker Machinery

Colliery	Tonnage	Kw.-Hr.	Kw.-Hr. Per Ton
A	51,232.15	133,000	2.5960
D	20,456.12	14,000	0.8211
L	24,082.16	35,000	1.4533
M	20,499.02	143,300	6.9911
G	35,301.16	29,140	0.8254
J	38,805.00	29,100	0.7743
	190,378.01	383,540	2.01

Item III—Ventilation

Colliery	Tonnage	Kw.-Hr.	Kw.-Hr. Per Ton
B	39,600.01	78,645	1.9859
C	17,050.02	57,395	3.3662
G	35,301.16	63,360	1.7948
J	38,805.00	36,840	0.9493
K	6,424.13	11,190	1.7418
F	36,475.05	6,900	0.1891
	173,656.17	254,330	1.4643

Item II—Drainage

Colliery	Tonnage	Kw.-Hr.	Kw.-Hr. Per Ton
B	39,600.01	25,100	0.6338
C	17,050.02	25,100	1.4715
D	20,456.12	9,200	0.4497
G	35,301.16	38,170	1.0812
J	38,805.00	123,100	3.1722
	151,213.11	220,670	1.4593

Item VII—Compressed-Air

Colliery	Tonnage	Kw.-Hr.	Kw.-Hr. Per Ton
B	39,600.01	87,100	2.2000
C	17,050.02	87,100	5.1091
G	35,301.16	168,200	4.7651
	91,951.19	342,400	3.7242

pumping is necessary and many long conveyor lines have to be operated under the conditions prevailing at that particular plant.

Item III shows the power used in mine ventilation. This item varies considerably owing to the variation from mine to mine in the number and lengths of the gangways, travels, breasts, etc., which need ventilation.

Item IV shows the power used in removing the water from the mines. The mines designated as *A* have a flowing tunnel and therefore need no pumping. *B*, *C*, *D*, *G* and *J* are the only mines equipped with electrically operated pumps and consequently all the others fail to appear in this table.

Item V shows the power used in lighting the outside buildings around the mines. This also is not a constant quantity per ton mined, for it depends on the number and size of the buildings lighted.

Item VI shows the power used in hoisting and lowering the men and material to the surface and includes all the hoisting of men, timber, rails, supplies in general, rock, etc., whether done at one or more shafts.

Item VII shows the power used in compressing air, which is conducted by pipes into the mines and used for drilling coal and rock.

Item VIII shows the power consumed in stations for charging the small portable storage batteries used by the underground employees for their electric cap lamps.

Meters Reveal Wasteful Night Consumption

Item IX is a summary of the other tables. These tabulations are only for a month their value largely consisting in comparing costs from month to month at the same mine. After making such a comparison it is easy to find out where power is being wasted and to bring about a saving. Watt-hour meters also make it possible to separate the power used at night from that used during the day, and as a result in many cases the waste of power during the night can be eliminated.

The saving in power made possible by using watt-hour meters pays liberally for the installation of the meter and its upkeep, for it tells the operator just where power is being used, and when it is excessive steps are invariably taken to reduce it to a minimum.

The kilowatt-hours per ton based on the whole production and power used is shown in Table IX as 5.2056. Since this method of tabulation was introduced the figure has been growing steadily less and less and has not reached its minimum yet.

Experiments on the effects of breathing carbon dioxide have been conducted at the Pittsburgh (Pa.) station of the U. S. Bureau of Mines under the direction of Dr R. R. Sayers, chief surgeon of the bureau, and A. C. Fieldner, supervising chemist. About 2 per cent of carbon dioxide in oxygen produced a slight increase in lung ventilation, but no subjective symptoms; 5 per cent in oxygen caused an increase in lung ventilation of about 100 per cent, but no other signs or symptoms; 7.2 per cent produced about 200 per cent increase in lung ventilation, and moderate perspiration and a slight fulness in the head were experienced after breathing the mixture for 10 minutes; 9 to 10 per cent produced about 300 per cent increase in lung ventilation, and the subject complained of frontal headache and was dizzy and perspiring at the end of 10 minutes. About 8 per cent of carbon dioxide in oxygen was breathed by some of the subjects for as long as 45 minutes, but the breathing was very laborious, and dizziness, headache and perspiration were marked. In fact, to have done any work while breathing this mixture would have been extremely difficult.

Blows or Sucks Dust from Electric Motors. Preventing Short-Circuits

MANY mining plants have no compressed air with which to remove the dust from motors and generators and in other cases there are substations where compressed air is not available. Consequently need is felt for equipment in portable form that will blow away the dust that collects on the various parts of electrical machinery and switches. The Premier Handy, manufactured by the Electric Vacuum Cleaner Co., Inc., of Cleveland, Ohio, is such an appliance. It has the further advantage that it can be used as a vacuum cleaner when that is desired.

The illustration shows how the apparatus is used to draw dust from the generator or motor. By detaching the dust bag and the hose and by attaching the latter to the orifice from which the bag has been removed, the vacuum cleaner is changed into a cleaner operating by compressed air. The machine as designed for mine service has an air-cooled motor and weighs 6 lb. The motor is universal and will operate on either alternating or direct current. The mouth of the cleaning tool is made of soft rubber that cannot mar or scratch anything and will not be broken if struck by a moving object.

In many cases where compressed air is readily available it does not pay to pipe it to every motor. The vacuum cleaner can readily be attached to an electric lamp socket and in this way will be made available without wiring, piping or preliminary expense. Then too, when using it as a blower, dry air is furnished. The air from compressors often is wet and the moisture not only rusts the machinery but short-circuits it.

Taking Dust from Commutator

By using an electric motor it is unnecessary to pipe compressed air to machines for dusting purposes. Furthermore the dust is not blown off, to settle elsewhere, but can be sucked into a bag.

By Washing Only a Part of the Coal Mined, Lowest Ash and Sulphur and Largest Yield Are Attained*

Standardized Screening Methods Make Comparisons Possible—How Coal Was Screened in Practice—Only Coal Passing Over Four-Mesh Screen Will Be Washed—Finer Coal Will Be Added to It Untreated

By G. R. Delamater
Harrisburg, Pa.

THE washery at which the tests described in this article were made was originally intended to deal with the coal coming entirely from certain mines in Pennsylvania all operating in the same bed. At that time 92 per cent of the coal fed to the washery appeared in the cleaned product, and the ash content in the refuse was always above 50 per cent. Even then a certain quantity of fine material found its way into the refuse.

During the late war, when coal was confiscated by the government and replaced by other coal from all over the states of West Virginia and Pennsylvania, we found ourselves facing a difficult problem, for there were never two consecutive days during which the coal mixture would be alike. In fact, each day's mixture usually contained coal from six to ten mines and the product of as many as 129 mines was represented in the washery feed during a single thirty-day period. To adjust the plant to such a variable feed so as to attain maximum efficiency naturally was difficult, but, all circumstances considered, it was regarded as fortunate that results as good as those attained were obtained.

Tests from which the data here presented were obtained represent a plant operation covering three months during the year 1919. Samples of the raw coal, washed coal and refuse were carefully taken daily, and screen tests made of each, the data herein given representing the composite results of this work.

Test Screen Gives Coal Standard Treatment

In making these screen tests it was desirable that great accuracy be obtained, and, realizing that in order to be comparative such tests should be conducted as nearly as possible under identical conditions, it was decided to use a Ro-Tap shaker screen set manufactured by the W. S. Taylor Co., of Cleveland, Ohio. Fig. 1 shows this apparatus, which is one in which the sieve pans at all times are given identically the same rotary movement, the same number of revolutions and taps per minute and, by means of an automatic clock-controlled electric switch, each test is carried on for exactly the same length of time.

As will be noted from the charts and tables, eighteen screens were used and they ranged from 1.05-in. clear opening down to 200 mesh. After studying the various screens used for work of this nature it was decided to adopt the Tyler standard screen set, which has as its base a 200-mesh sieve made from 0.0021-in. wire having a clear opening of 0.0029 in., which is that adopted as standard by the U. S. Bureau of Standards. The 100-mesh and the 20-mesh sieves in this screen scale also meet the specifications adopted by that bureau, so three of the sieves are in accord with its standards.

The ratio between the different sizes of this screen scale has been taken as 1.414, or the square root of 2, as recommended by Ritinger. Thus the width of opening in each successive sieve is exactly 1.414 times that of the preceding sieve, making the area of opening in each successive sieve just double that of its predecessor. When desirable, every other sieve may be skipped or taken out. This results in half the screens being used, but the ratio of width of opening will be 2 to 1.

By skipping two sizes a ratio of 3 to 1 will result and by skipping three sizes a ratio of 4 to 1 will be obtained. At the time these tests were started it was my belief that the results probably would show that nothing coarser than 16-mesh coal could be bypassed around the washery except possibly in the low-sulphur coals such as those of the Rocky Mountain district, where high ash is the only undesirable feature and in which it was probable that 8-mesh would be the limiting size. I was, therefore, much surprised in finding plus 8-mesh to be the permissible size and that a screen with about ¼ in. of clear opening could be used in actual plant operation.

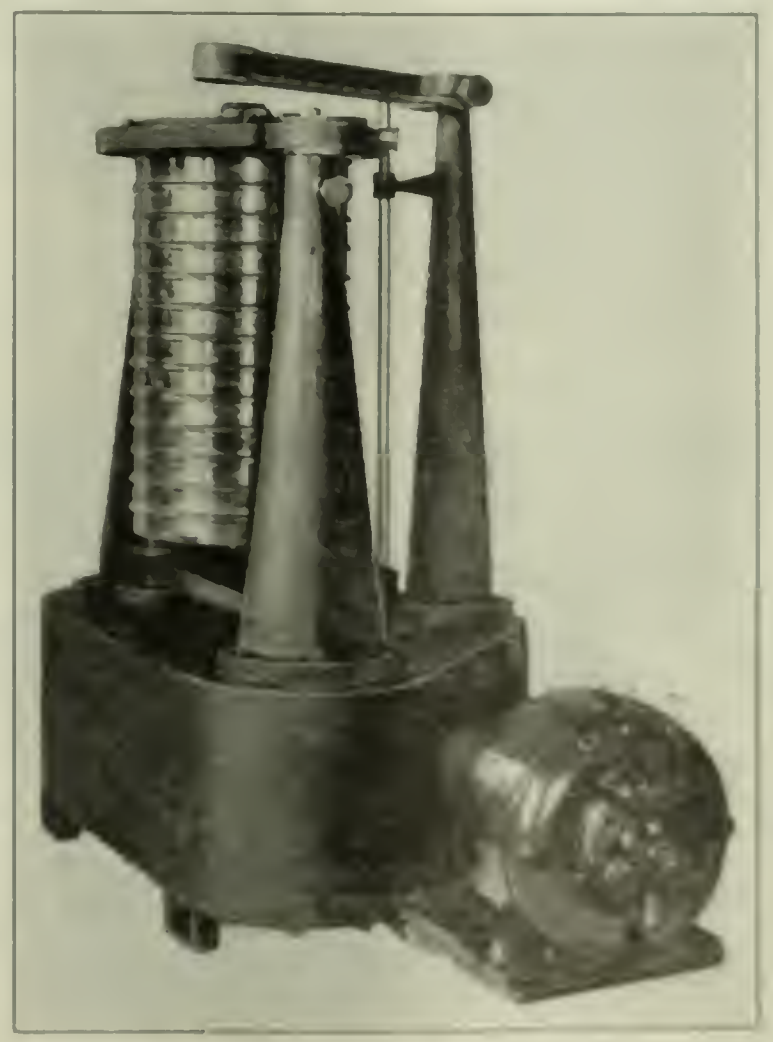

FIG. 1—A SHAKER SCREEN MAKING THIRTY SIZES

Apparatus gives uniform movement, equal conditions and number of taps, equal time control and therefore comparable results. In the tests described in this article seventeen coal screens and one pan of blind screen were used. A time switch stops the current when the specified duration of the test is completed

*Second of two articles by G. R. Delamater. The first appeared in *Coal Age* Oct. 26 and was entitled "Problems of Illuminating Coal Washing and Measures Now Being Taken for Their Solution."

FIG. 2—SCREEN VIEW OF SCREEN FOR WASHER USE

Heavy load especially that expects to transmit to screen to prevent the escape of fine dust. The vibrating mechanism is on top, free from contact with the material being screened. It is enclosed in a metal dustproof housing.

In addition to this I realized that the cost of screening out such coal in the tonnages it would be necessary to handle would be a serious matter, as no screening equipment then known seemed well adapted to such service. Fortunately, about the time this work was completed the W. S. Tyler Co. placed the Hum-mer electrically vibrated screen on the market and a 6-ft. machine of this type was purchased and placed in the washery in such manner that the method proposed could not only be tested under real operating conditions but the feed to the screen could be altered to any desired tonnage so that its efficient capacity could be determined.

This screen was kept in constant daily operation for one year, careful record being made of the results obtained under all weather conditions. The principal effect of these was to modify the moisture content of the coal. It should be noted that the data represented a full year's test and so enabled us to study all the many coal mixtures which were delivered to the washery. The result of this one year's demonstration was so gratifying that the entire plant was finally equipped with screens of this type, not, however, without careful consideration of all the other available screening equipment.

It was found that this machine, which had a total screen area of 30 sq.ft., would efficiently handle from 80 to 110 tons of coal per hour, depending, of course, upon the moisture content, the maximum of which slightly exceeded 10 per cent. The power consumption was 1 hp. The screen cloth was such as to give the equivalent of a ¼-in. clear square opening.

Figs. 2 and 3 show the type of screen used. Simplicity, accessibility, high capacity, low power consumption and ability to operate without lubrication are its chief advantages.

The vibrator is a simple solenoid magnet operating on a 15-cycle alternating current. A small motor-generator set converts the available power (which in our case was 25-cycle) to that required by the machine. All the screens used in this plant combined required 4 hp. of electric energy.

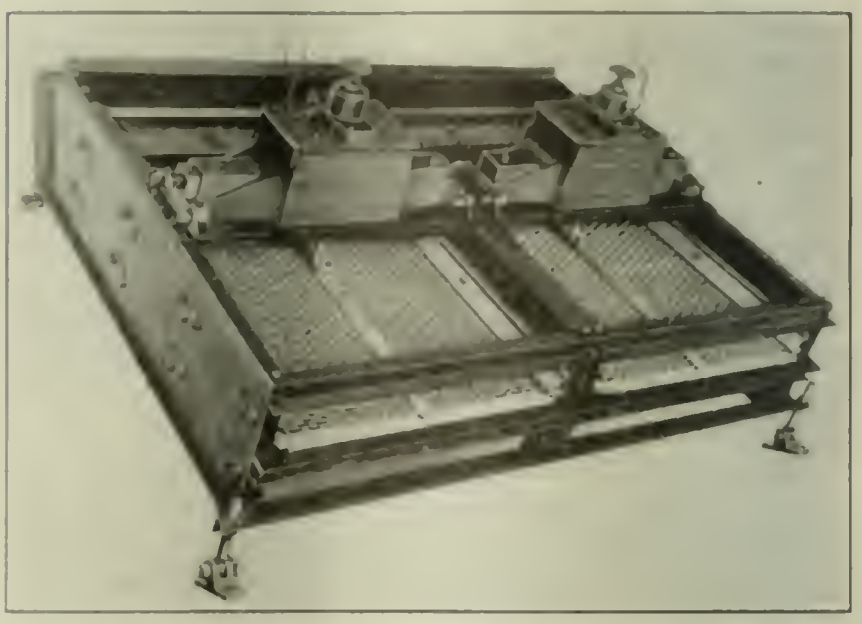

FIG. 1—SCREEN WITH DUSTPROOF HOUSING OMITTED

The screens are vibrated by the electric vibrators on the bridge above them. The handwheel regulates the intensity. Fifteen-cycle current is used. The vibration is not subdued by the presence of a heavy load. There is no make and break; the alternations of the current pull up and release the armature at high speed.

FIG. 3—LIFTING OUT A SCREEN FOR REPLACEMENT

The frame is cast so that right-hand side is a small shaft in which a wrench may be inserted. By turning this shaft the tension of the screen can be adjusted to suit the moisture content of the load. One man can readily make this adjustment.

No movement whatever is imparted to the frame of this machine, only the screen cloth being moved and this at the rate of 1,800 vibrations per minute. This cloth is normally stretched up at drum-head tension yet is quickly adjustable. Also by means of the small hand wheel on the top of the vibrator the strength of vibration may be instantly adjusted while the screen is in operation.

Though the rapid vibration of the cloth would alone result in effective screening, another feature of this machine undoubtedly has much to do with its high capacity. In hand screening simply shaking the sieve pans is a slow process. Anyone who has performed this work well knows the result of shaking the sieves over a table where they may be frequently bumped meanwhile. The result is much greater rapidity of screening. The armature of the machine here illustrated at each upward stroke strikes suitably arranged blocks, thus imparting to the screen cloth an effective impact.

Prior to the installation of these screens, when all the

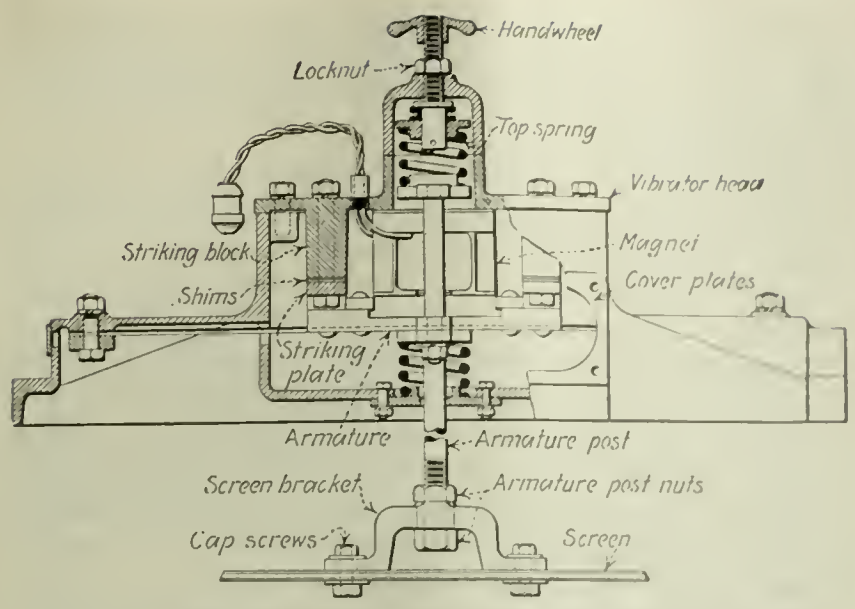

FIG. 5—ELECTRIC VIBRATOR WITH SCREEN ATTACHED

The strength of the vibration is regulated by the handwheel. The low-frequency current is generated by a small alternator operated by a high-frequency circuit. The piece across the poles of the magnet—"the armature," as it is termed—goes back and forth as the strength of the magnet increases or declines.

coal was washed, twelve jigs, three settling tanks with Luhrig dewatering elevators and three Elmore centrifugal coal driers were employed. The washed coal yield ranged from 86.12 per cent to 89 per cent when good grades of coal constituted the mixture. The moisture content of the finished washed-coal product was 8 per cent whereas the ash and sulphur contents were 6.73 per cent and 1.15 per cent respectively. The washery operation was such at all times as to maintain these figures with but slight variation.

After installation of the screens only six jigs, one settling tank with dewatering elevator and one Elmore drier were used. The ash and sulphur content of the finished product remained the same, or 6.73 and 1.15 per cent respectively, and the moisture content was reduced to 5 per cent or less. The yield ranged from 92.5 per cent to 95 per cent, there being three straight months during which the higher figure was obtained. This, of course, was because of improvement in the quality of the raw coal coming to the washery.

The accompanying charts are designated by letter and the tables by number. The tables are somewhat

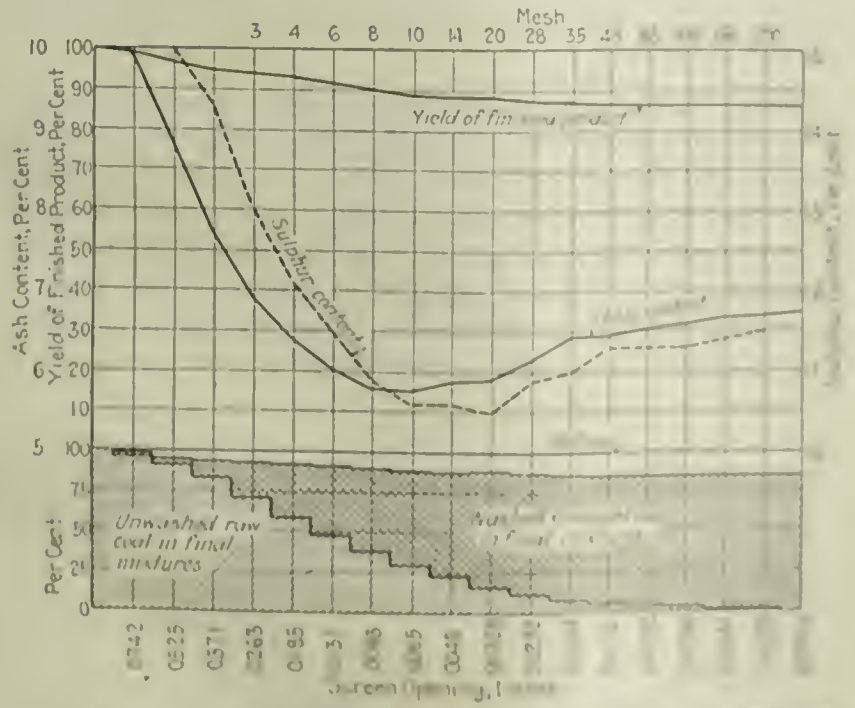

CHART A—MIXING WASHED COAL ABOVE A CERTAIN SIZE WITH UNWASHED COAL BELOW THAT SIZE

Taking coal that would go through a screen opening of 1.66 in. as basis for examination, the ash and sulphur content and yield of finished product are given that would result from washing all the coal larger than a certain size and adding to it unwashed all the coal below that size. Note how much more successful is part washing than entire, or even almost entire, washing.

lengthy but are submitted so that those desiring to make a more detailed study of this problem may have all necessary data available. The charts are, of course, a more convenient form for the same data, bringing out with greater clearness, if with less accuracy, the results obtained.

In making screen tests as well as analyses of the raw coal, washed coal and refuse, it has always been my experience that it is impossible to obtain results throughout which will check to exact figures. I mean by this that, theoretically, the ash and sulphur content of the washed coal and refuse when combined should equal the amounts of the ash and sulphur in the raw coal. The best safeguard against unreasonable variations from the theoretically correct figures is to take large samples with great care. This procedure was followed in this work.

The raw coal was—rightly, I think—taken as the base of all calculations in making corrections, and for this

CHART B—SULPHUR IN EACH SIZE OF RAW COAL, WASHED COAL AND REFUSE

Note that this chart gives the sulphur in each size and the sulphur in all sizes above the size given to be all sizes below that size but merely sulphur in the coal which passes through the next larger screen and is held on the screen of which the opening is given.

reason the tonnage of this raw coal and its ash and sulphur contents are charged against the washery and must be accounted for. Likewise, the washed coal is the resulting plant product which is invariably carefully sampled and weighed, and the samples analyzed. It was, therefore, considered in this work that the figures resulting from the screen tests and analyses of the washed coal must be accepted at their face value and be left uncorrected.

Some Coal Always Is Broken

Because some of the coal is sure to be broken as it passes through the washery the percentages of sizes in the washed coal and refuse when combined cannot be expected to equal exactly the percentages of the same sizes in the raw material. For an entirely different reason the ash and sulphur content as determined by an analysis of the washed coal may rightfully be accepted as binding and not subject to correction as are those of the refuse, for whatever is not found in the refuse that calculations of the content of the washed coal would show should be there is nevertheless properly chargeable to the refuse or waste product of the plant. It is

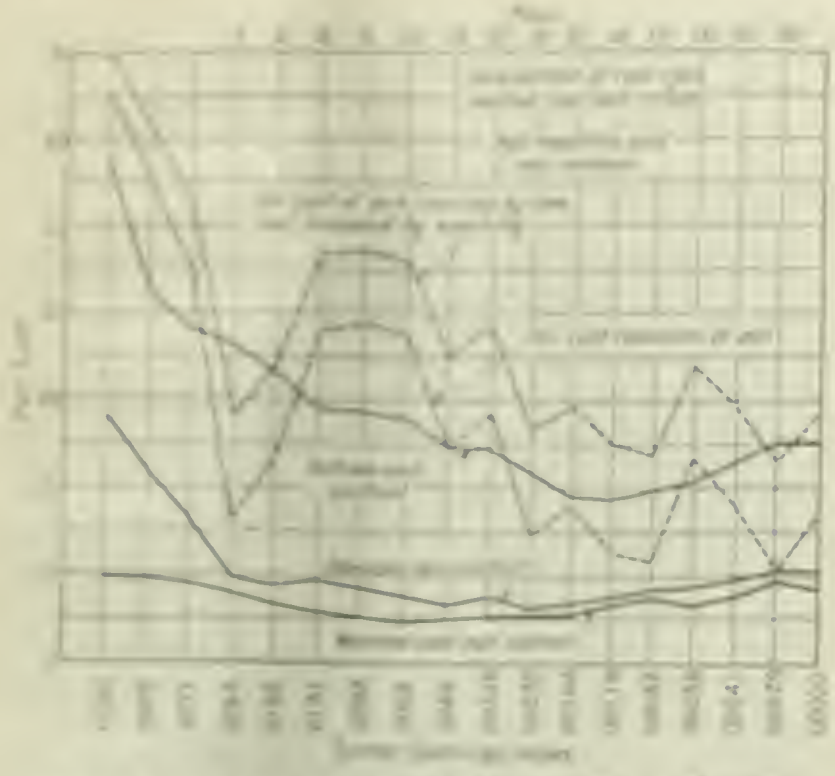

CHART C—SIZE IN RAW COAL, WASHED COAL, AND REFUSE

This chart, size is based on the mesh held by the screen that is rejected as an oversize and passed by the next larger screen. It shows the degree to which the particular size recorded fails to be rejected of the ash.

almost from the washed coal no matter where it has gone.

Under that assumption the percentage of washed coal yield as determined by actual weighing at the coke ovens (all weights being, of course, converted to a dry basis) was accepted as correct and used as the base for corrective calculations.

It was found that the theoretical calculations based on the percentages of the various sizes of the raw coal and their percentages of ash and sulphur content resulted in a total ash and sulphur content of the raw coal which checked closely with the actual analysis made of the original raw-coal samples. The total resulting from these calculations for ash and sulphur therefore was accepted as the correct figure in order that these figures might be used for the corrective calculations to follow.

Analyses for the ash and sulphur content of the various sizes in the washed coal also were accepted as correct. Using the washed-coal yield as a base, the correct figures for the percentage of each size in the washed coal were calculated. Then, using the raw-coal data and the corrected washed-coal figures, the percentages of sizes in the refuse and their ash and sulphur contents were calculated.

This method, of course, resulted in corrections to nearly all the percentages of sizes in both the washed coal and refuse as well as to some of the analyses for ash and sulphur content of the various sizes in the refuse. However, none of these was radical.

Referring now to the diagrams, chart *A* sets forth quite clearly the unexpected result disclosed by this work. It was found that both a lower ash and sulphur content will be found in the finished product if only a portion of the coal be washed, the remainder being by-passed around the washery and mixed with the washed product from the other portion.

On this chart each vertical line represents an individual scheme of washing, being entirely independent of each of the others set forth by the other lines. This chart arrangement will hereafter be called class *X*,

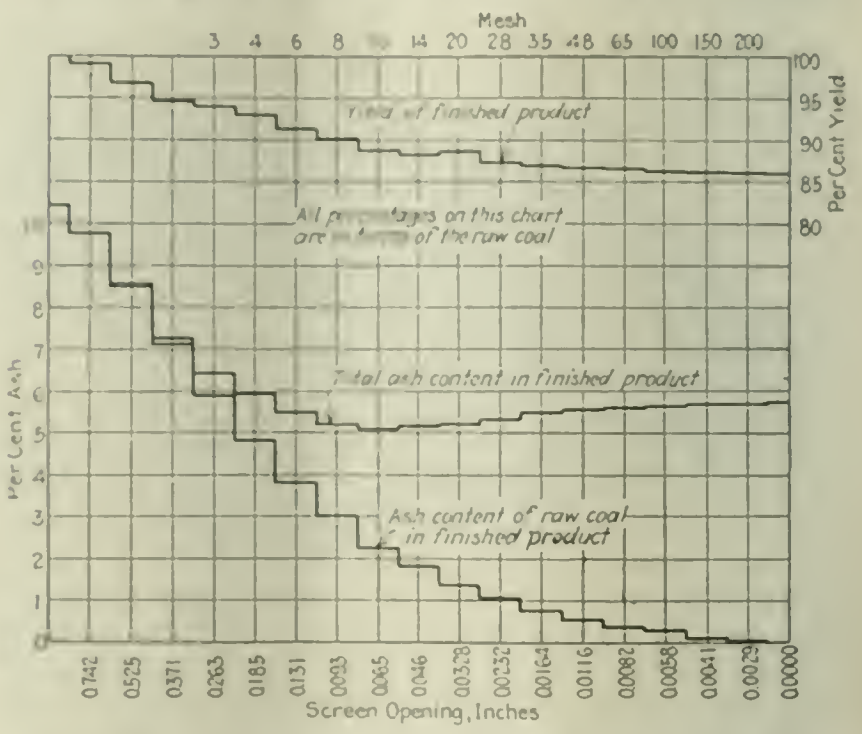

CHART E—ASH CONTENT WHEN ANY ONE SCREEN IS USED TO SELECT COAL FOR WASHING FROM REST OF COAL

Chart shows percentage of the ash in the raw coal appearing in the finished product, the total ash content and the yield of that product.

whereas those wherein each vertical line represents an individual screen size will be called class *Y*. For example, the fourth line from the left on chart *A* represents the 3-mesh screen with 0.263 sq.in. clear opening. The curves intersecting this line designate the percentages in each instance that will result if all the coal retained on that screen be washed and the washed product resulting be mixed with the unwashed raw coal passing through this screen.

The lower portion of this chart depicts the proportions of raw and washed coal in the final mixture. It will be noted that the yield curve for the finished product declines steadily as the percentage of coal washed is increased.

It will be seen that with the 20-mesh screen the lowest sulphur percentage was obtained whereas it was with the 10-mesh screen that the percentage of ash in the product reached its minimum. The 14-mesh would therefore be the ideal size for the screen if a balance were struck between maximum ash and sulphur reductions. However, in our instance (and I think the same will apply to most of the washeries where the coal is

CHART D—EFFECT ON REDUCTIONS OF SULPHUR AND ASH WITH YIELD ON EACH SIZE

The two extremes of the commonly used sizes were here taken in being accumulated by the screens in reducing the ash and sulphur to their limits and their losses. The diameter of these is small and the degree to which they can be reduced is also small, as it is found further on in many cases.

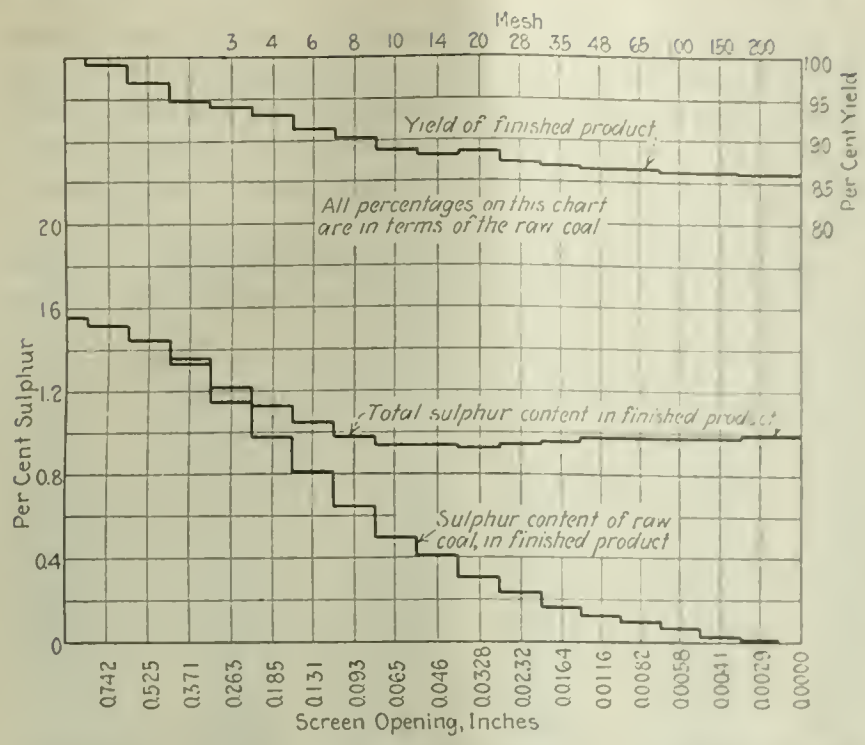

CHART F—SULPHUR CONTENT WHEN ANY ONE SCREEN IS USED TO SELECT COAL FOR WASHING FROM REST OF COAL

Each ordinate shows the result that would be obtained if all the coal that would be held on such a screen were washed and all the coal that would be passed by that screen were mixed with the former to form the final product.

cleaned for the manufacture of metallurgical coke) the washery received no premium for producing a coal product having a sulphur content such as would result in the manufacture of a coke of less than, say, 0.95 per cent sulphur. One per cent of sulphur in the coke was the maximum allowable at this plant, the blast-furnace department claiming no advantages for any lesser content, yet making strenuous objection to anything higher. As a washed coal that contained 1.25 per cent of sulphur gave a coke with a flat 1 per cent of that injurious ele-

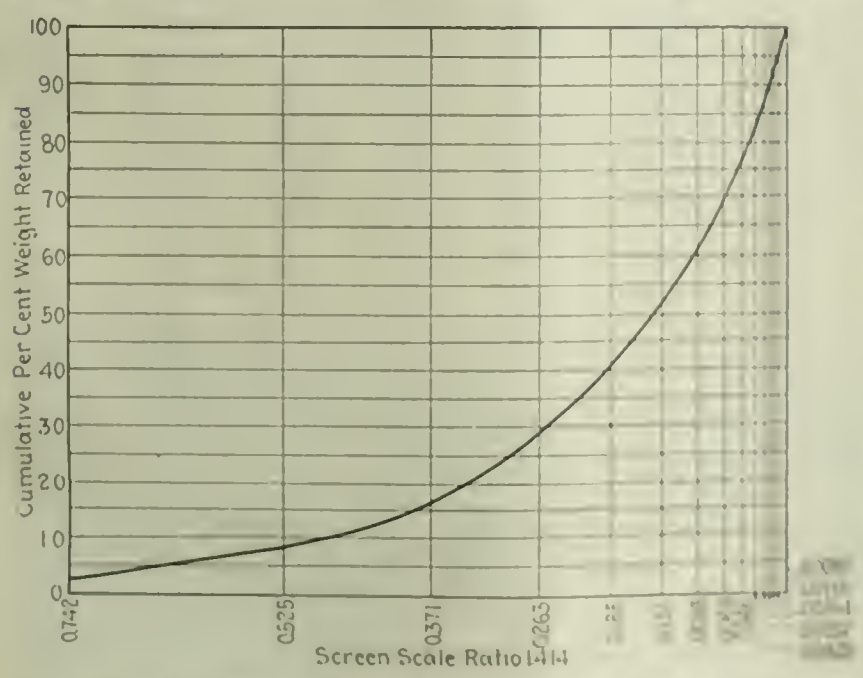

CHART G—RAW COAL RETAINED ON SCREENS

This is a cumulative diagram, the quantities plotted on the ordinates (which represent the screen openings) being those of all the coal that would refuse to pass through that particular screen opening. Consequently the quantities gradually increase until with the blind screen at the end 100 per cent is reached

ment, it was always our custom to operate the washery so that the sulphur content of the washed coal would remain as constant as possible at 1.15 per cent. This assured us of always maintaining a reasonable margin of safety.

For this reason no advantage would accrue from using the 14-mesh screen, which would result in a washed-coal yield of 88.42 per cent. Instead we adopted the 6-mesh screen having a clear opening of 0.131 in. This resulted in a washed-coal yield of 91.5 per cent with a sulphur content of 1.15 per cent. After making a complete screen installation at this plant, because of some improvement in the quality of the raw coal and of a feeling that we could operate with reasonable safety when aiming at a finished product containing 1.20 per cent of sulphur the 4-mesh screen with 0.185 in. clear opening was adopted. This resulted in a normal washed-coal yield of 93.13 per cent, but, as previously stated, at times a yield of 95 per cent was actually obtained.

In explanation of this rather unexpected result atten-

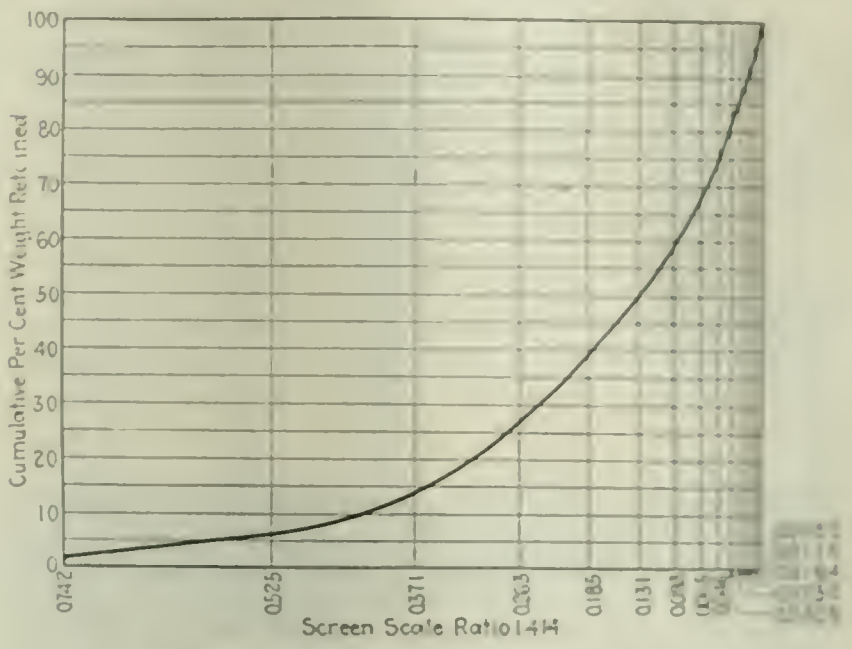

CHART H—WASHED COAL RETAINED ON SCREENS

This is also a cumulative diagram and shows at each point in the curve what any one screen would do if it were the only screen by which the coal was sized. That is, the ordinates represent the entire oversize of that particular screen, beginning however, with coal that passes a 1.05 opening, that being the size of coal exclusively considered in all these tests.

tion is called to the other illustrations. In Charts *B* and *C* (class *Y*) the raw and washed coal, ash and sulphur curves show quite clearly the sizes in which the maximum reductions may be accomplished as well as the sizes that are but little affected by washing. Chart *D* (class *Y*) is of interest in that reduction and yield curves travel exactly opposite one another although the general trend of the reduction curve is more rapidly downward than is the yield curve upward. The breaks, however, in each are quite uniform.

Charts *E* and *F* (class *X*) are of interest in that they

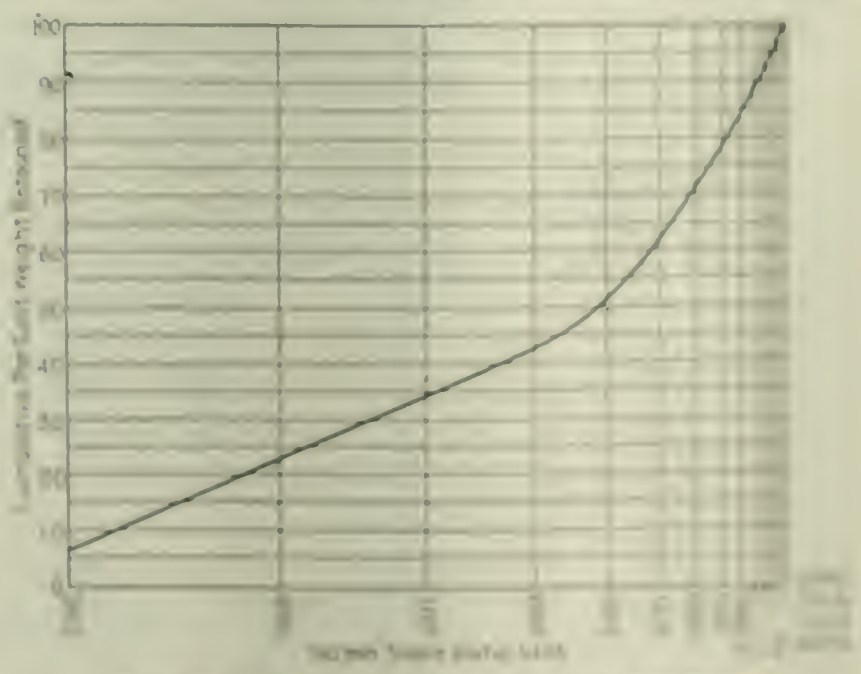

CHART I—REFUSE RETAINED ON SCREENS

Also a cumulative diagram like charts G and H. As in them also the screen sizes are not plotted at even distances but on a logarithmic scale. The lines being drawn at distances proportional to the screen openings

per factor than the others in showing the cause of the phenomena presented herein. The percentages all being in terms of the raw coal disclose the relation between the total ash and sulphur content of the finished product and its yield.

Referring to chart C (class Y), the ash curve for refuse indicates clearly the presence of free coal in this material in the sizes wherein but slight ash reduction is possible. This is particularly true of the sizes from the 20-mesh screen up to and including the 65-mesh. The radical break in the reduction curve for the 3- and 4-mesh screens while the refuse ash curve remains more regular proves the higher efficiency possible in the washing of the larger sizes.

Another consideration that must be borne in mind is that most of the coal treated falls within the larger

sizes. Thus any reduction of ash or sulphur accomplished in these sizes has a marked effect in decreasing the quantity of these substances in the total product. Note that the last four small grades, which carry the highest sulphur of any of the sizes separated, amount to only 4.7 per cent of the total raw coal.

Safe Handling of Railroad Cars at Mines*

BRAKES on railroad cars often are in poor condition, making it necessary for the car dropper to use extreme care to keep the cars from getting out of control and being wrecked. Sometimes the brake sticks and it is necessary for the car dropper to kick it off in order to start the car. Many accidents have been caused by the car dropper leaving the brakestick in the wheel and going below to kick off the brake. Often it releases its hold suddenly and in turning throws out the brakestick, hitting the car dropper on the head. A brakestick should be made with a hook on the end to prevent it from slipping off the brake staff and also to permit its being hung on the ladder, as shown in Fig. 1. In this way the brakestick will not fall on the car dropper and will be convenient for him when he climbs up to set the brake again. There are many cases on record where car droppers have been seriously injured by being hit on the head with the falling brakestick, which, made of iron, may easily knock a man senseless.

FIG. 2—EMPTY-CAR WALKING, ANOTHER UNSAFE STUNT

The trimmer who balances on the edge of a railroad car would take risk enough if he tried his acrobatics where on rails and exposed the ends made landing hazardous and where there were no cars moving on other tracks to distract and imperil him. In the railroad yard around a tipple is no place for gymnastics

Another common source of danger is the practice

Brakestick Accident

Instead of carrying his brakestick on the brake staff when about to kick off the brake at close to the coal [illegible] a trimmer [illegible] from the [illegible] carries it at arm's length. Only in this way can the [illegible] of the car [illegible] when the brake is released

FIG. 3.—NO CLEARANCE BETWEEN CARS AT SWITCHES

Accidents frequently occur from this cause, especially where the switch stand provided is insufficiently long. A signal device and method so as to be readily visible may be used to notify the engineer when he has lowered the car far enough to provide adequate clearance.

of standing on the brake platform to set the brake in the manner shown in the right half of Fig. 4. Men standing in this position have no way to save themselves in case the brakestick should slip; quite frequently have men fallen from the car and been run over as a result of this practice. The safe way is to apply the brake as shown in the left half of Fig. 4—with one hand on the brake of the wheel and the other applying the pressure to the brakestick. Then if it should slip or break, the man will not lose his balance, as he has a

Another danger, which is so apparent that it may seem almost foolish to point out, is shown in Fig. 3. Here the car is not moved far enough on the switch to clear, and a moved car coming down on the other track is about to bump into the corner of the first car. A fatality resulted recently when a man riding on the brake platform was caught and crushed between the corner of his own car and a moved car which did not clear on the switch.

Car droppers become so expert, and sometimes gain so much confidence in themselves, that they often walk along the edge of the car in going from one end to the other. There are a number of accidents recorded caused by men falling and sustaining serious injuries (see Fig. 2).

FIG. 4.—BEWARE OF RELYING ON THE BRAKESTICK

In the position shown in the left illustration no harm would result from the brakestick slipping. If the trainman, however, were in the position shown in the right illustration and the brake should slip, he would lose his balance and might be seriously injured or killed.

Scene from Colliery on Brownies Creek

TO Ivor Livingston, of Paint Creek, Ky., we are indebted for the illustration of a mine car and its colliery surroundings at Brownies Creek, Bell County, Kentucky, about twelve miles from the railroad station which is located at the mouth of the creek. No railroad runs up the valley. The mine is operated by farmers for their own coal supply. The gage of the car track is 24 in. Every part of the car is of wood except for the few nails in the bed. The rails also are of that material.

Specifications Proposed for Tool Steel

A TENTATIVE specification for carbon tool steel has been prepared by the American Society for Testing Materials and has just been submitted to industry. The specification requires that the steel shall be made by either or both the crucible and electric processes, with the exception of class *C*, which may also be made by open-hearth methods. It shall conform to the following requirements as to chemical composition:

CHEMICAL SPECIFICATIONS FOR CARBON TOOL STEEL

Elements Considered	Class *A* Per Cent	Class *B* Per Cent	Class *C* Per Cent
Carbon	varying	varying	varying
Manganese, maximum	0 400	0 450	0 600
Phosphorus, maximum	0 020	0 025	0 035
Sulphur, maximum	0 025	0 035	0 040
Silicon, maximum	0 350	0 350	0 250

The carbon percentage shall be as ordered, the specifications varying by ranges of 0.1 per cent, with rejection limits plus or minus 0.025 per cent. As an illustration, tool steel may be ordered with a carbon range from 0.60 to 0.70 per cent, with rejection limits of 0.575 and 0.725 per cent, or from 0.75 to 0.85 per cent, with rejection limits of 0.725 and 0.875 per cent. The permissible variations in the size of the material ordered shall be determined by agreement between contractor and purchaser. The material shall be free from injurious defects and have a workmanlike finish. The analysis shall be made in accordance with methods for testing carbon tool steel contained in the Book of the American Society for Testing Materials, Standards of 1921. Criticism of these specifications should be addressed to G. H. Woodroffe, secretary of Committee A-1 on Steel, Parkesburg Iron Co., Parkesburg, Pa.

IN THE STEEL GALLERY used at the Pittsburgh (Pa.) station of the U. S. Bureau of Mines in conducting experiments regarding the explosibility of coal dust, the following determinations have recently been made: (1) The explosibility of standard Pittsburgh coal dust in atmospheres of methane varying from 1 per cent to 8 per cent; (2) the explosibility of standard Pittsburgh coal dust in atmospheres of carbon dioxide varying from 1 per cent to 33⅓ per cent; (3) the effect of varying percentages of moisture upon the explosibility of standard Pittsburgh coal dust.

Problems of Operating Men

Edited by James T. Beard

Practical Advantages Gained in Use of Double-Conductor Cables

Room Tracks Seldom Well Bonded—Single-Conductor Cables of Little Use Under Certain Conditions—Possible Short-Circuit in a Double Conductor Offset by Its Many Advantages

KINDLY permit me to offer a few suggestions in regard to the use of single and double cables for electric gathering locomotives. This question was asked by an Ohio electrician, *Coal Age*, Oct. 12, p. 594. In the excellent reply given to this inquiry, the several types of cables used by gathering locomotives have been described, and the conditions explained under which single and double conductors should be used.

The fact is well known that the use of a poorly bonded return rail, not only causes a great loss of time by reason of burned-out armatures, but also results in a loss of power, making the locomotive unable to pull its load.

Practically, this condition is most frequent in rooms and cross-entries where the same attention is not given to keeping up the roads, as on the main headings. In many cases, corroded fish-plates have been used and these have not been securely bonded to the rails. It is easy to see that there is every chance for an armature to be burned out, or for the locomotive to be short of power when a single-conductor cable, which is dependent on a rail return, is used.

Advantages and Disadvantages of Different Types of Cables

Another great disadvantage, in the use of a single-conductor cable, occurs when a locomotive is badly derailed, which will happen at times. Much time is then lost in trying to get a sufficient return to enable the motor to operate and assist in putting the locomotive back on the rails.

Although there is a considerable disadvantage in a two-conductor cable, by reason of a possible short-circuit occurring within the cable, I believe that the saving of armature burn-outs and delays caused by insufficient power, due to poor bonding of the rails when using a single conductor, will more than offset any liability to possible short-circuiting of the wires in a double-conductor.

Also, it is my opinion that the advantages gained in the use of a double-conductor largely outweigh the difficulties of splicing this conductor, in the event a splice has to be made. We must not forget, also, that where a change of track is necessary, the use of a double-conductor cable obviates the necessity for securing good bonding on the rails in making such changes.

These advantages give me a decided preference in favor of double-conductor cables, which should be of the concentric type mentioned in the reply to the inquiry.

Linton, Ind. JOHN R. LUXTON.

Eliminating Expense of Packwalls, Longwall-Panel System

Face headings replace the gateways maintained by building packwalls—Single face headings, however, provide no means of ventilating when drawing back pillars.

IN AN effort to eliminate the expense of building packwalls for the maintenance of roads or gateways to reach the working face, in the longwall-advancing system of mining, M. L. O'Neale described a method of driving face headings, keeping them a little in advance of the longwall face. (*Coal Age*, Vol. 21, p. 877.)

These headings were to be driven three abreast and, while affording an easy means of reaching the longwall face, also provided for maintaining good ventilation when drawing back the pillars after the headings had reached the limit of the panel. In reviewing this improved method of longwall work, W. H. Luxton, in his letter, Sept. 21, p. 455, suggests driving a single, face heading instead of employing the triple-entry system proposed by Mr. O'Neale.

Proposed Plan to Avoid Paying Entry Yardage

Mr. Luxton expresses the opinion that the proposed system can be simplified and the cost of its execution much decreased, by avoiding the large expense for yardage due to driving three face headings where but one is required. Evidently, he has not stopped to think how his plan of driving single headings would work out when drawing back the pillars flanking the heading.

No doubt, it would save yardage to drive a single heading, and the plan would work all right in the advancing stage; but how would it serve when it became necessary to draw back the pillars. If I am not mistaken, the goaf would then have closed tight against the pillars on the sides where the coal had been taken out.

It has been my experience that, in work of this kind, it is impossible to provide the necessary circulation of air to permit the pillars to be withdrawn. I believe that, if the pillars are to be taken out, at least one air course must parallel the face heading. While this air-course would be of no particular advantage in the advancing stage, it is essential for circulation, in the work of robbing out the pillars.

It is possible, of course, to maintain a fair circulation of air along the worked-out side of the face-heading pillars, by building good packwalls a few feet from the solid coal forming the pillars. However, if I understand rightly, the purpose of the proposed plan was to eliminate the necessity of building and maintaining these packwalls. In my opinion, the cost of maintaining such airways would exceed the cost of driving an extra heading in the coal.

Original Plan of Flanking Places Increases Tonnage

Referring, now, to the original proposition presented by Mr. O'Neale, I see no objection to his idea of flanking his face headings, on each side, with a place running parallel to it. I believe these places would be driven wide and would involve no yardage expense. Driving such flanking places would have the immediate advantage of increasing the tonnage obtainable from each face-heading system, which would have a tendency to decrease the general cost of production.

One practical advantage gained by keeping these flanking places a yard or so ahead of the longwall face is that they provide convenient places for the machine to start and finish a cut along the face. Also, these places provide needed room for the machine where it will be out of the way when loading out a cut.

The advantage of these flanking places is even greater when chain machines of the so-called longwall type are employed. I was recently in several Belgian mines where they are using these machines, manufactured by a well known American firm. The results obtained are surprisingly good. In these mines, it was found not only advisable but necessary to provide all longwall faces with flanking places of the kind suggested and for the reasons I have mentioned. F. C. CHENEY,

Consulting Engineer.

Occurrence and Causes of "Bumps" in Coal Mines

Meaning of the term "bumps"—Nature and instances of their occurrence—Probable causes of the phenomena—Methods suggested to prevent such happenings

IN THE REPLY to an inquiry regarding a method of working that would permit the danger from sudden outbursts of gas, COAL AGE, Aug. 24, p. 296, reference was made, incidentally, to the opinion prevailing that earthquakes take place in the strata and which the miners term "bumps."

The term has recently come to have much significance in this locality and, as I am rightly informed, the same is true in a number of other coal-mining districts in the Northwest. Most of our miners have learned by experience and fully realize the danger that is imminent when they hear those ominous sounds, as of the working of tremendous forces hidden in the strata around and about them.

It is well to explain, in the start, the meaning of the term "bumps" in its application to coal mining. Thomas Graham, former chief inspector of mines for the Province of British Columbia, in a paper read at the Joplin meeting of the Mine Inspectors' Institute of America, June 13, 1916, makes the following statement:

MEANING OF THE TERM "BUMPS"

"The term 'bumps' is a somewhat local expression used to describe the various sounds that betoken the movement of the strata overlying the several coal seams operated in the Crows Nest Pass coal field. These bumps, although usually accompanied by more or less heavy discharging of gas, are not in the nature of the outburst of gas and coal I have just described.

"The Coal Creek Colliery has been the seat of most of the bumps, which were sufficiently severe to shake the houses in the village and, at times, cars and other movable materials were displaced in the mine."

It was but six months after the reading of Mr. Graham's paper (November, 1916), another series of bumps occurred in the No. 3 East mine, at Fernie, B. C., more severe than any that had preceded them. A description of this mine and the effect of the November bumps will be found commencing on page 144 of the report of the Minister of Mines, British Columbia, for the year 1917.

INVESTIGATIONS AND REPORT BY FEDERAL BUREAU OF MINES

George S. Rice, engineer, Federal Bureau of Mines, who investigated the phenomena, by request of the minister of mines, describes these bumps as manifestations of pressure occurring only in mines at great depth, usually exceeding 1,000 ft. In his report, Mr. Rice states:

"If the measures overlying the mine are soft and pliable, such as shale, bumps will not occur, although coal squeezes may take place. Bumps, therefore, occur only when there are massive and rigid beds above, such as sandstone, conglomerate and limestone.

"Mine squeezes originate where the pressure thrown on the mine pillars is sufficient to crush them, or the immediately overlying roof or underlying floor is too weak to withstand the load put on it through removal of part of the natural support by the excavations; but such squeezes will only result in bumps, as stated previously, when there are rigid rocks of great thickness above."

INSTANCES OF THE PHENOMENA OCCURRING ELSEWHERE

The same report describes the phenomena as not being confined to any single district, similar occurrences having been manifest in coal mines working under the Book Cliff mountain, in Utah, and in the Carbonado mines, in the State of Washington, where the workings were under the foothills of Mt. Rainier. In both of these two latter cases, the cover exceeded 2,000 ft. in depth.

The phenomenon has also proved a serious menace, the report states, to a South Staffordshire coal mine, in Great Britain. This mine was working the ten-yard seam, averaging from 24 to 30 ft. in thickness and lying at a depth of 1,500 ft. below the surface.

To my mind, this entire subject of the causes and means of preventing bumps is of peculiar interest and importance. Not a few mining men, in localities where the phenomena have been manifest, regard them as something mysterious. It is in the hope of enlightening the minds of any who hold to such ideas, that I have offered these remarks. It is my earnest hope that the subject will be discussed from an intelligent standpoint and that methods of working will be outlined that will afford a maximum degree of security against these dread occurrences.

CONCLUSIONS REACHED BY THE INVESTIGATORS

The investigation made by the Federal Bureau of Mines was undertaken at the request of the Minister of Mines, Province of British Columbia. The conclusions reached by Mr. Rice, in conference with W. F. Robertson, provincial mineralogist, Thomas Graham, then chief inspector of mines, and district inspectors T. H. Williams and George O'Brien, should prove of great interest and value, wherever the mining of coal is being prosecuted under deep cover and the overburden consists of rigid strata that refuse to break when the extraction of coal has caused a general subsidence of the mine roof over a large area. On this point, the investigators conclude as follows:

"That bumps occur only when there is deep cover over the mine and where there has been a subsidence of the roof over an extraction or squeezed area; the rigid strata above has not flexed downward, but spans the sunken area. When the span, through continued mining and widespread subsidence, becomes too great for the rock strata to bridge over, enormous masses may fall and while the distance may be only a few feet or even a few inches, the sudden arrest of rock masses weighing possibly thousands of tons will cause a shock wave in the underlying stratum, which gives the effect of a local earthquake.

"After one rigid stratum has given way in the interior of the measures, there is opportunity for similar giving way of successively higher strata; but, it is thought, with less and less effect on the mine workings, as the spaces become more or less filled with broken rock and the blow is cushioned; also, as the vertical distance above the workings becomes greater with each successive fall."

May we not hope to hear from others on this important matter?

MINE FOREMAN.

———, B. C., Canada.

Testing a Safety Lamp With a Carbide Lamp

Method used by one fireboss to test his safety lamp—After cleaning and putting lamp together, it is exposed to acetylene gas from a carbide lamp—Discussion wanted.

REGARDING the question of testing a safety lamp before taking it into the mine, allow me to say for the benefit of other firebosses that, in all my experience in firebossing, I have never yet tested my lamp by blowing into it.

It has always been my practice, and I consider it a safe one, to test the safety lamp by exposing it to acelylene gas generated in a carbide lamp. It is my belief that any lamp that passes this test is safe to be taken into the mine and exposed to a body of firedamp.

After the lamp has been thoroughly cleaned, put together and lighted, it has been my custom to take a carbide lamp and put it near the gauze of the safety lamp, allowing the gas generated in the former to pass into the combustion chamber of the safety, where it fires and burns.

My claim is that if there is any imperfection in the gauze, or if there is any leakage below the glass, because of imperfect washers, the flame of the gas burning within the safety lamp will pass out and ignite the gas surrounding the lamp. I have used this method of testing my lamp a long time and have never known it to fail. It is my habit to apply the same test to the lamps of the miners in my charge.

Shickshinny, Pa. FIREBOSS.

Need of Closer Supervision in All Underground Work

Visits to many mines show need of good foremen—Mines suffer when foremen are employed for a short time only.

HAVING made a number of visits recently to different mines, I have been impressed with the thought that the employment of an efficient, private

mine or safety inspector, where a company is operating several mines, appears almost a necessity.

A recent writer in *Coal Age* has drawn attention to the lack of interest displayed by foremen who drift from place to place, such men seldom remaining in one place longer than they are able to get out cheap coal by robbing the mine. In every such case, the loss to the company is hardly realized until the damage to the mine has been done.

My observation, in going from place to place, has showed me more clearly than ever before, the need of employing good foremen. In several instances, I have observed where the employment of a supervising inspector would easily save his wages in many ways.

By preventing waste, improving the ventilation and drainage of the mine and increasing the daily tonnage by systematizing the haulage and hoisting of coal, he would reduce the cost of production and make his services valuable to his employers.

These remarks are offered only by way of suggestion, fully realizing as I do that there are many good mine foremen whose work requires no checking up or supervision. At the same time, it cannot be denied there are numbers of indifferent and careless foremen and others who are unpractical, and that a large saving can be effected by closer supervision of their work on the part of the mine foreman and assistant foreman.

Chambersville, Pa. JOHN BUGGY.

Inquiries Of General Interest

Locking Car on Self-Dumping Cage

Self-Dumping Cage Equipped with Sidehoops and Lugs to Hold Car in Place—Trouble Caused by the Lugs Failing to Work at Times When Needed—Some Form of Additional Lock Desired

WE HAVE a problem that we are minded to present to *Coal Age* and its practical readers, hoping that they will be able to offer suggestions that will solve our difficulty. The proposition is as follows:

At one of our mines, we are using what is known as the Bond cage, manufactured by the William Ellison Machinery Co., St. Louis, Mo. This cage is equipped with two steel loops or hoops that fit over the wheels of the car, on each side of the cage. Their purpose is to hold the car on the rails when the cage is dumping. Besides these loops at the sides of the car, there are also two upright lugs that catch the wheels in front and prevent the car from running across the cage.

Now, our trouble is that these lugs, at times, fail to work, with the result that the car is free to run across the cage far enough to be caught between the cage floor and the curbing of the shaft. When this happens, there is sure to be a wreck that tears out the guides, before the engineer is aware that anything is wrong. We have tried to figure out some way of putting in an additional lug on the platform or some other place on the cage, for the purpose of giving additional security against accident. We shall very much appreciate any suggestions that will accomplish the desired result.

————, Ill. SUPERINTENDENT.

The correspondent has not stated the precise position of the upright lugs, or given other information that would make clear the exact situation in hand. If cars are to be caged from both sides of the mine, at the shaft bottom, the upright lugs mentioned would have to be movable to permit cars to enter the cage from either side. On the other hand, if cars are caged from one side of the shaft only, these upright lugs would be permanent or fixed in position at the back of the cage. The statement that these lugs, at times, fail to work suggests that they are movable; but how their movement is actuated is not explained.

Different forms of devices are used to lock cars on a self-dumping cage. The most common and probably the most serviceable device consists of two movable steel hoops, one on each side of the cage, and actuated by a lever that automatically engages a projecting lug in the shaft, as the cage rises to the point where it is dumped. Instead of a hoop reaching over the tops of both wheels, four movable hooks are sometimes employed, two on each side of the cage, one hook holding each wheel firmly in place as the cage is dumped.

We have seen a fixed hoop or strap so arranged as to project over the tops of both wheels. These are fixed in a position not to interfere with the car running on and off the cage, while holding the car on the rails as the cage is dumped. In this case, however, the car is locked on the cage automatically by a carriage spring fixed firmly to the floor of the cage beneath the car. This spring is made to engage a lug on the bottom of the car.

At other times, a heavy iron rod is attached to the floor of the cage, the end of the rod being bent at right angles so that it can be turned upward in a position that will prevent the car from running forward when the cage is dumped. This arrangement, however, is not recommended. Many readers will probably have other forms and methods to suggest for securing the car to the cage when dumping, and we shall be glad to learn of the most satisfactory means employed.

Three-Brothers Problem

Problem to find radius of circle circumscribing a triangle—Solving a triangle when the three sides only are given.

KINDLY permit me to ask for the solution of a problem over which I have puzzled vainly, for some time. The problem has a practical bearing, as it relates to the central location of a well, for three brothers whose homes form the vertices of a triangle, the sides of which are 10, 11 and 12 chains, respectively. The problem is to locate the well at an equal distance from each brother's house.

Evidently, this is a question of finding the radius of the circumscribing circle of this triangle. I have endeavored to

solve the problem graphically, by erecting perpendiculars at the middle point of each side of the triangle. The intersection of these perpendiculars should give the center of the circumscribing circle. But, I have been unable to calculate the length of the radius of this circle, which is the distance of the well from each brother's house.

Carrolltown, Pa. T. J. McCUE.

The correspondent has stated his problem correctly. The location of the well is at the center of the circle circumscribing the triangle formed by the lines joining the three houses. Referring to the accompanying figure, this location is at *O*, which is the intersection of the three perpendiculars *Ox*, *Oy*, *Oz*, erected at the middle point of each respective side of the triangle *ABC*.

The problem involves the solution of a triangle having its three sides given. The first step is to calculate the angle at *A*, using the formula

$$\cos A = \frac{b^2 + c^2 - a^2}{2bc}$$

In this formula, the sides lying opposite the respective angles *A*, *B*, *C* are indicated by the corresponding small

Finally, in the right triangle AOx, the hypotenuse AO, which is the required radius of the circumscribing circle, is equal to the square root of the sum of the squares of the two sides;

$$AO = \sqrt{Ox^2 + Ax^2}$$

$$= \sqrt{2.24^2 + 6^2} = 6.4 \text{ chains}$$

Therefore, the desired central location of the well is 6.4 chains from each of the three houses.

Examination Questions Answered

Mine Managers' Examination Nova Scotia. 1922

(Selected Questions)

QUESTION—*The total rubbing surface of a square airway being* 180,000 *sq.ft., the length of the airway* 5,000 *ft., and the quantity of air passing* 88,000 *cu.ft. per min., what is the velocity of the air current, in feet per minute?*

ANSWER—Since the rubbing surface, in an airway, is the product of the perimeter and length of the airway, the perimeter in this case is 180,000 ÷ 5,000 = 36 ft. The airway being square, each side is one-quarter of the perimeter, or 36 ÷ 4 = 9 ft. The sectional area of this airway is, therefore, 9 x 9 = 81 sq.ft. Finally, the velocity of the air current is 88,000 ÷ 81 = 1,086 ft. per min.

QUESTION—*If it becomes necessary to stop a fan for repairs, how will you keep the same class of gas in the workings? What precautions should be taken before stopping the fan?*

ANSWER—A mine generating a considerable quantity of gas should be provided with duplicate fans, each fan having a capacity sufficient, when running alone, to keep the mine free from gas. A mine thus equipped is in no danger should the necessity arise for shutting one of the fans temporarily, for repairs.

In the absence of such equipment at a gaseous mine, it may not be possible to keep the mine in a safe condition, for any length of time, after shutting down the fan. In that case, the men should be notified and withdrawn promptly from the mine. It is not safe to take any chance by permitting the men to work when the customary means of ventilation is temporarily disabled.

It may happen that, under favorable conditions, there is sufficient natural ventilation to keep the main airways clear, which will greatly assist the safe withdrawal of the men. Such natural ventilation, however, cannot be expected to keep the working places safe and clear of gas, while the fan is not working.

QUESTION—*If* 10 *hp. produces* 20,000 *cu.ft of air per min., in a mine, what horsepower will be required to produce* 35,000 *cu.ft. per min., under the same conditions?*

ANSWER—In mine ventilation, the horsepower producing circulation in a given mine, under like conditions, varies as the cube of the quantity of air produced. In other words, the horsepower ratio is equal to the cube of the quantity ratio. Then, calling x the horsepower required to produce 35,000 cu.ft. per min., where 10 hp. produces 20,000 cu.ft. per min., we have

$$\frac{x}{10} = \left(\frac{35{,}000}{20{,}000}\right)^3 = \left(\frac{7}{4}\right)^3 = \frac{343}{64}$$

$$x = \frac{10 \times 343}{64} = 53.6 \text{ hp.}$$

QUESTION—*Many explosions have been caused by blownout shots. Describe fully the precautions that a manager should enforce to prevent explosions occurring from this cause.*

ANSWER—Blownout shots are chiefly caused by overcharging a hole; insufficient tamping; locating the charge too deep in the solid; or failing to properly ream or sludge out a shot before firing the charge. A blownout shot is sure to result when the line of least resistance extending from the charge to the free surface of the coal, corresponds more or less closely with the axis of the hole. This is called a deadhole. Blownout shots may result from using too quick a powder or different grades of powder in the same hole.

In order to prevent these occurrences, the mine manager should make and enforce strict regulations, in regard to the blasting of coal and the use of explosives. Only permissible explosives should be used and all shots should be examined, charged and fired by competent persons, authorized to perform this work.

QUESTION—*In a mine ventilated by three splits of air, A, B and C: A is* 500 *yd. long and* 5 *x* 6 *ft., in section; B is* 600 *yd. long and* 5 *x* 4 *ft., in section; C is* 700 *yd. long and* 7 *x* 3 *ft. in section; all starting and rejoining at the same point. If the quantity of air in A is* 35,000 *cu.ft. per min., how much air will B and C each take if subject to the same pressure as A.*

ANSWER—Assuming natural splitting in which no regulators are used in any of the airways, the quantity of air passing in each split is proportional to the split potential. Therefore, calculating the relative pressure potential, for each of the given splits, we have the following:

A, 5 x 6 ft., 1,500 ft.; a = 30 sq.ft.; s = 33,000 sq.ft.

B, 5 x 4 ft., 2,400 ft.; a = 20 sq.ft.; s = 43,200 sq.ft.

C, 7 x 3 ft., 2,100 ft.; a = 21 sq.ft.; s = 42,000 sq.ft.

To shorten the calculation, we take the lowest relative values, which are for the areas, 30, 20, 21; and, for the rubbing surfaces, 330, 432, 420. Using these values, we find the several split potentials as follows:

$$\text{A, } X_a = a\sqrt{\frac{a}{s}} = 30\sqrt{\frac{30}{330}} = 9.045$$

$$B, X_b = \quad = 20\sqrt{\frac{20}{432}} = 4.303$$

$$\text{C, } X_c \quad = 21\sqrt{\frac{21}{420}} = 3.240$$

Finally, assuming Split A passes 35,000 cu.ft. per min., the quantities in each split being proportional to their relative potentials, we have

B, 9.045 : 4.303 :: 35,000 : x = 16,650 c.p.m.

C, 9.045 : 3.240 :: 35,000 : x = 12,540 c.p.m.

QUESTION—*Supposing* 9,000 *cu.ft. of air per minute circulates through a regulator* 30 *x* 20 *in.; it is desired to find how much air will circulate if the opening is made* 30 *x* 30 *in.*

ANSWER—If it is assumed, which is the probable meaning of the question, that this regulator is placed in an airway and the opening of 30 x 20 in. is increased to 30 x 30 in., it is not possible to calculate the increase in the quantity of air passing through the regulator, without knowing the equivalent orifice of the mine or airway. Enlarging the opening in the regulator increases its orifice, without increasing the orifice of the mine or airway, and there is a lack of proportion due to this change.

On the other hand, considering the regulator by itself and assuming a constant pressure, under which the air flows through the opening, the increase in quantity would then be proportional to the increase in area, giving 30/20 × 9,000 = 13,500 cu.ft. per min.

This, however, is not the case with a regulator placed in an airway. Assuming a constant power producing the circulation in the airway, when the regulator opening is enlarged, the pressure due to the regulator falls and the quantity of air in circulation is increased, which increases the pressure due to the frictional resistance of the airway. The increase in quantity will then depend on the relative resisting powers of the airway and the regulator.

Commission's Fact-Finding Machinery Taking Form; Technical Experts Drafted to Assist

By Paul Wooton
Washington Correspondent of *Coal Age*

The fact-finding machinery being set up by the President's coal commission is now taking definite form. While the commissioners expect to obtain much of their information from the broad conclusions of outstanding men engaged in coal production, distribution, wholesaling and retailing, a vast amount of data must be collected by a technical staff. That portion of the work which deals with costs of production will be under the immediate direction of David L. Wing, whose title is to be expert investigator. As the work progresses Mr. Wing will gather other statistical facts. C. E. Lesher, editor of *Coal Age*, has been drafted to direct the engineering investigations which the commission will conduct. Coal specialists from various bureaus will be transferred to the commission.

Assurances of co-operation have been given by each national association connected with the coal business. A statistical program is being worked out which it is believed will cause little dissension. It is being arranged so that those engaged in the business can furnish the information in the way it is carried on their books. Roderick Stephens, president of the Retail Coal Merchants' Association, has conferred at length with members of the commission, as has a committee representing the public utilities. More formal conferences are in contemplation. The one with the retailers is to be held the latter part of November. There is every evidence that the commission will have the wholehearted co-operation of the whole coal business.

Where statistical and other information is furnished by one branch of the industry, arrangements are being made whereby the other branches concerned and the commission itself can check the figures as they are being compiled. In this way it is hoped to compile statistical data the correctness of which will be admitted by each branch of the industry.

Since the government's law officers decided that Dr. George Otis Smith may not lead a double official life, it became necessary for him to resign his position as director of the United States Geological Survey. After having discussed the matter personally with the President, Dr. Smith presented a formal resignation in which he, among other things, said: "Some plans I have had in mind for the betterment of the Geological Survey's contributions to the public are unfinished, even after my fifteen and one-half years as director. I, therefore, regret this break in my work, yet, while I hope I may have an opportunity for further service with the Geological Survey, I appreciate so keenly the importance to the nation of the task you have entrusted to the coal commission that I am willing to make any sacrifice needed to enable me to devote all my energies to that special work for the next eleven months."

In his reply and in a statement issued at the White House the President explained that Dr. Smith's resignation is of a temporary character and that he will be reappointed as director of the Survey when his duties with the coal commission shall have been concluded.

The same provision of law bars Judge Alschuler from serving in two official positions. The President will ask Congress to make an exception in this case, but until such a law is passed Judge Alschuler will not qualify as a member of the commission. He will work with the commission, however, in an informal capacity.

The Geological Survey came in for praise in a recent editorial in the *Philadelphia Public Ledger*. In discussing the coal commission the editorial says that "the appointment of George Otis Smith was an act for which Mr. Harding cannot be commended too highly. The Geological Survey is purely scientific, non-political, magnificently efficient and brilliantly administered."

The coal commission has been endeavoring since its organization to arrange for the appearance before it of both Secretary Hoover and Secretary Davis. Other duties of these secretaries, however, have made this impossible.

Coal Commission Unable to Undertake Work Outside of Main Investigation

Although the mandate from Congress to the United States Coal Commission was to procure information on all problems connected with the coal industry, the purpose of the commission's investigations as set forth in the law is to aid, assist and advise Congress in its efforts to help the industries of the country and the people generally and to maintain the uninterrupted flow of commerce among the states. To these general instructions Congress attached specific orders for reports and recommendations, the first of which is required not later than Jan. 15 next. The scope of the task laid upon the commission recently appointed by President Harding is plain as well as its urgency, so that it is evident that no work outside the main investigation can be undertaken.

Already the commission has received complaints regarding insufficient local supplies of coal, exorbitant prices demanded by dealers and other evidences of unsatisfactory functioning in the coal business. A telegram just received from an Oklahoma citizen, for example, calls for immediate investigation of a mine-labor dispute, undoubtedly a distressing local condition which affects consumers as well as producers of needed coal, yet the requested action by the coal commission is not possible. The commission could easily dissipate its energies in following up such complaints, and without results, for the law gives it no executive functions, and the commission therefore would be without authority to act in relief of these individual instances, which after all are but localized symptoms of the disorder affecting the whole industry.

Nine-Tenths of Coal Industry's Troubles Laid to Inadequate Transportation

If adequate transportation could be had for coal it would remedy nine-tenths of the trouble within the industry. A statement to that effect is being accentuated in official circles in Washington. Unless some step is taken to provide more transportation for coal, the difficulties of the industry will increase, especially those which pertain to labor, until strikes become annual occurrences. A production to that effect has been made by a high administration official. Intermittency, he contends, may be charged almost entirely to lack of transportation, while overexpansion may be attributed largely to the same cause. In the opinion of this official, unnecessary mines would be eliminated if the highly efficient properties could rely upon a constant car supply. As it is, the well-equipped and efficient mine is penalized each time there is a car shortage. Each serious emergency costs the public a greater sum than the entire cost of the new cars that are needed to straighten out the situation.

In that connection it is pointed out that the country has come through this emergency at much less cost than was the case during the emergency period which preceded it. The average price of coal during the emergency growing out of this year's strike is figured as having been $3.77, compared with $6.30 during the preceding emergency. Thus far this year, it is asserted, there has been no single case in which a public utility has been forced to suspend operations or any

[illegible] to [illegible] the lack of coal. This is attributed in part to the voluntary restraint in prices charged and because of the foresight of industries and public utilities in stocking up before April 1. Despite the long strike, prices never would have gotten out of hand, it is declared, had there been sufficient transportation.

The shortage of coal cars is only one symptom of the systematic starvation to which American railroads are being subjected. New lines are not being built in proportion to the increase in population and in industrial activities. Terminal facilities have become woefully inadequate, adding greatly to the time of each car's turn-around. The hope is expressed that the Interstate Commerce Commission soon will have time to take up work in connection with consolidations. Since it is clearly unconstitutional to compel consolidations, it is believed that some inducements will have to be held out to effect them. One plan is to reinvest recaptured profit in the group from which it came. It is becoming more and more evident that something must be done to save the weak roads. Railroad financing generally must be made easier. Nothing can be gained by plunging railroads into receiverships.

Philip S. Smith to Head Geological Survey: David White Retires as Chief Geologist

Resignation of Dr. George Otis Smith as director of the United States Geological Survey, so that he could qualify legally as a member of the President's coal commission, will place the full responsibility for the conduct of the Survey during the next eleven months in the hands of Philip S. Smith, who has been serving as the Survey's

PHILIP S. SMITH

administrative geologist. The new director has spent practically his entire career on the staff of the Survey and is thoroughly conversant with its work. While his outstanding accomplishments have been on his geological and research studies in Alaska, he has had wide experience with many phases of the work done in his bureau. He is widely known as an unusually capable geologist, with which he combines great executive capacity.

Simultaneously with Dr. George Otis Smith's resignation came the announcement that David White will retire as the Survey's chief geologist to resume his research work. He will be succeeded in the office of chief geologist by W. C. Mendenhall. Mr. Mendenhall has been a member of the Survey staff for 20 years. His geological field work has extended from the southern Appalachians to Alaska. For more than two years he has served as geologist in charge of the Land Classification Board. This latter place will be filled by the promotion of Herman Stabler. In connection with Mr. White's retirement as chief geologist Dr. George Otis Smith contributes this comment:

© Harris & Ewing

DAVID WHITE

"On Nov. 16 David White will have completed ten years' service as chief geologist. This contribution to the administration of the Survey has been at the expense of his own scientific work, even though he has thereby increased the scientific value of the work of his associates. It seems fair that his oft-repeated request for permission to return to his own geological studies should now be granted, not only to gratify the natural desire of an investigator who has laid aside research problems one after another but to promote the advancement of our science.

"The return of Mr. White to productive research suggests anew the sacrifice involved in the administration of scientific work. Administration by scientists is the keynote of the Survey's policy, yet the intellectual cost item involved in this drafting of our best investigators must be kept down to minimum. Had I been free from other demands on my time this past summer, I would have taken this occasion to start a somewhat radical reorganization of the geological branch, the chief purpose of which would be to reduce its administrative overhead—too many geologists are giving valuable time to work for which they were not trained. Necessarily now this task of simplifying the organization must be left to the new chief geologist and acting director, but I ask for them a sympathetic acceptance of the proposal for a less elaborate but more elastic grouping of the activities of the branch. Not machinery, but product, is the measure of efficiency in a government scientific bureau."

W. C. MENDENHALL

How the Coal Strike Affected Bituminous Coal Stocks Shown by Government Report as of Oct. 1

By W. F. McKenney, F. G. Tryon and E. E. Finn*

The government's report on coal stocks, just issued, places the total bituminous in the hands of commercial consumers at 22,000,000 tons on Sept. 1, and 28,000,000 on October 1.

To many observers of the coal market who were matching up the statistics of production with their own estimates of consumption during the strike, it will appear surprising that there could be anything like 22,000,000 tons left in the possession of consumers when the settlement came.

This article attempts to show how the country adjusted itself to the shortage in supply, and how the deficit between production and consumption was met. Details of the present condition of stocks will be found elsewhere.

There are two elements in the above-ground reserve of coal. The first element is the stocks in the hands of consumers. The second element is the coal in transit, coal on docks, in intermediate storage yards, en route in cars or vessels, and also for convenience coal stocked by the producer at the mine. Both of these elements may be drawn upon to meet a deficit in supply and they will be considered in turn.

Bituminous Stocks in Hands of Consumers

It is not feasible to collect statistics of the stocks of domestic consumers nor of the smallest steam buyers. Statistics of stocks must, therefore, be commercial consumers' stocks, including retailers.

The total quantity of soft coal in the hands of commercial consumers on Sept. 1, 1922, was between 20,000,000 and 24,000,000 net tons—probably 22,000,000 tons. The quantity on Oct. 1 was about 28,000,000 tons. This does not include coal in the cellars of domestic consumers, concerning which statistics are not available, nor steamship fuel, nor coal on the docks at the head of the Lakes, which is classed as coal in transit.

From the following table and Fig. 1, which shows the same data graphically, the coal history of the past year may be read. In anticipation of the strike, consumers began stocking up in January, and when the storage questionnaire was circulated on March 1, one month before the strike, their replies indicated stocks of 52,500,000 tons. The work of building up reserves continued through March, and from the facts of production it may be safely assumed that by April 1 stocks were at least 63,000,000 tons, although the figure cannot be given accurately because no questionnaires were circulated on that date. Then came the strike. For five and a half months consumption exceeded production and the deficit had to be paid out of stocks. There was much speculation as to how long the reserves would hold out. Early in August the disturbed state of the market plainly showed that the danger line was near. The experience of 1920 had indicated that when stocks fall to 20,000,000 tons,

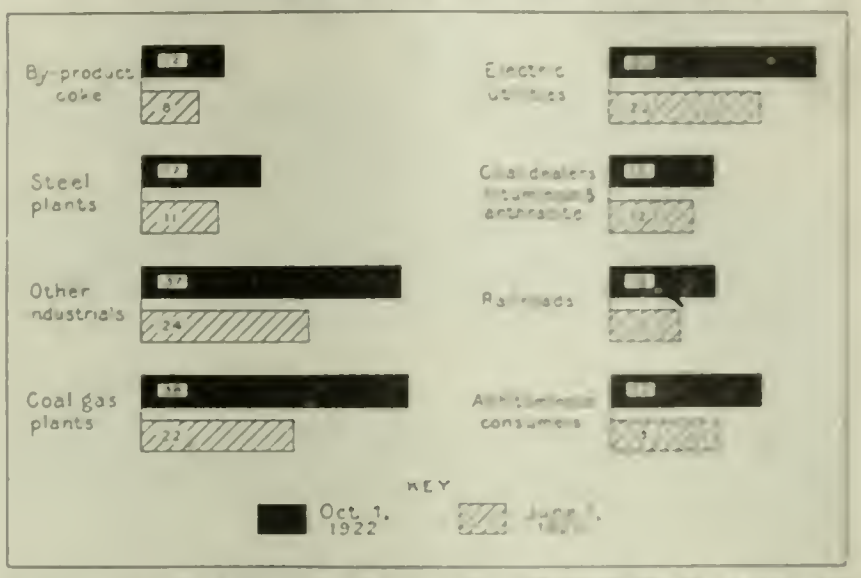

FIG. 2—DAYS' SUPPLY HELD BY DIFFERENT CLASSES OF CONSUMERS ON OCT. 1, 1922, AND ON JUNE 1, 1921

At the rate coal was being burned in September, 1922 (including alleged curtailment of consumption by [illegible]), the stocks of soft coal on Oct. 1, 1922, were sufficient for [illegible] days. At the lowest point on record—June 1, 1921—the stocks were sufficient for only 15 days. Since Oct. 1 [illegible] have continued to increase.

high prices and anxiety result, and it was, therefore, very significant that the stock-taking of Sept. 1, only ten days after the general resumption in the Central Competitive Field, should show 22,000,000 tons.

ESTIMATED TOTAL COMMERCIAL STOCKS OF BITUMINOUS COAL IN THE UNITED STATES

	(Net Tons)		
October 1, 1916	27,000,000	January 1, 1921	[illegible]
October 1, 1917	28,100,000	April 1, 1921	[illegible]
July 15, 1918	39,700,000	August 1, 1921	[illegible]
October 1, 1918	59,000,000	November 1, 1921	[illegible]
Day of the Armistice	63,000,000	January 1, 1922	[illegible]
January 1, 1919	57,900,000	March 1, 1922	[illegible]
April 1, 1919	40,400,000	April 1, 1922 (a)	[illegible]
March 1, 1920	24,000,000	September 1, 1922	[illegible]
June 1, 1920	20,000,000	October 1, 1922	[illegible]

(a) The figures for 1918 in this table are based upon actual count. Beginning April 1, 1919, the figures are estimates based upon reports from a selected list of 5,000 consumers whose stocks in 1918 bore a known relation to the entire coal stocks.

(b) Subject to revision.

Analysis of all available data on supply and consumption shows that between March 1 and Sept. 1, the dates for which accurate stock figures are available, the total consumption and exports of American bituminous coal amounted to between 195,000,000 and 200,000,000 tons. This indicates a slight decrease in consumption as compared with the 1921 average, a decrease explained by (1) warmer weather, (2) actual curtailment of operations at some steel works, coke ovens, and industrial plants through scarcity or high price of coal, (3) shrinkage in exports and (4) postponement to autumn and winter of a large part of the movement of domestic coal.

But against this consumption of [illegible] tons there was produced or imported only [illegible] tons, leaving a deficit of 42,100,000 tons to be drawn from reserves. Of this deficit, about 30,500,000 tons was paid out of consumers' stocks, and the balance—11,600,000 tons—was drawn from the coal in transit.

Some of the deficit in supply during the strike doubtless was met out of the stocks of domestic consumers. The aggregate reserves of the householders, hotels, apartments, small office buildings and other consumers covered by this class run into the millions of tons. Some of these lay [illegible]

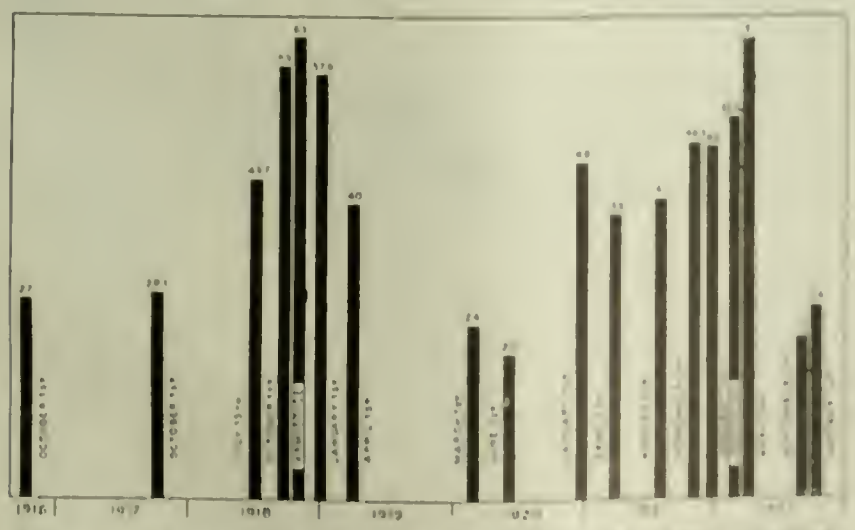

FIG. 1—TOTAL COMMERCIAL STOCKS OF BITUMINOUS COAL, OCT. 1, 1916, TO OCT. 1, 1922

Figures represent million net tons and include coal in hands of railroads, industrial consumers, public utilities and retailers. Coal for steamship fuel, on lake docks, and in transit is not included. Figures for 1922 are subject to revision.

*Published by permission of the Acting Director, U. S. Geological Survey.

FIG. 3—STATE SUPPLY OF SOFT COAL ON HAND AT INDUSTRIAL PLANTS ON OCT. 1, 1922

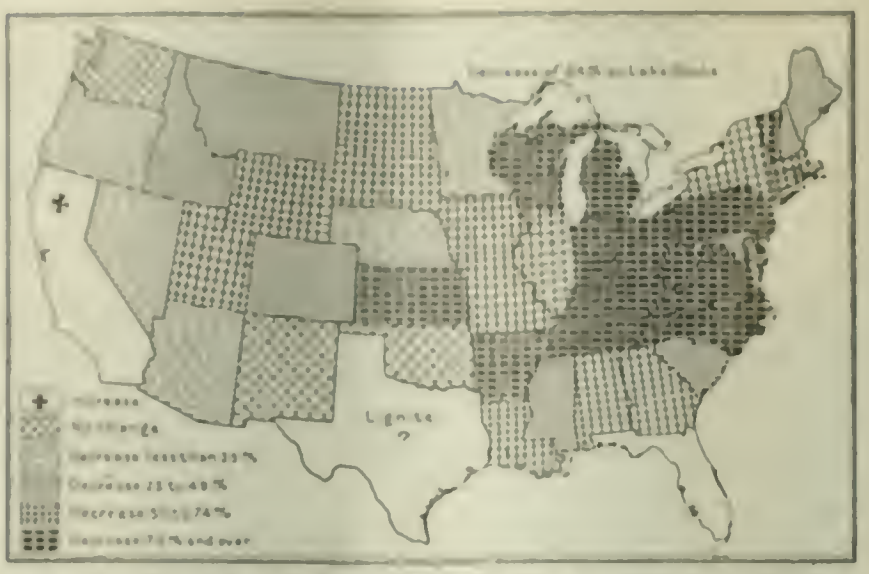

FIG. 4—HOW RETAILERS' STOCKS OF ALL COAL, ANTHRACITE AND BITUMINOUS, ON OCT. 1, 1922, COMPARED WITH THOSE ON NOV. 1, 1921

Stocks of bituminous coal in retail yards on Oct. 1 were about half what they were a year ago. Stocks of anthracite were barely 13 per cent of last year's stocks. The total stocks of retailers—including both hard and soft coal—showed a decrease of 67 per cent as compared with 1921. The map shows that the decrease was small in the Far West and most acute in the territory east of Mississippi River and north Alabama.

surplus in anticipation of a shortage, and all of them tend to draw on their reserves and postpone fresh purchases when coal is scarce and dear. This process no doubt facilitates passing a crisis in coal supply, though the extent of the relief may not be stated in tons.

Bituminous Coal in Transit

"Coal in transit" includes all coal mined and brought to the surface not yet delivered to the retailer or consumer. It resembles all in a pipe line or material in process in a manufacturing plant; it has inventory value but it cannot be fully realized upon without stopping the process. The quantity in transit has never been measured, but it evidently runs into many million tons. It fluctuates within wide limits and may be drawn upon to meet a deficit in supply. During the 1922 strike there was evidently a net reduction of about 11,000,000 tons in the coal in transit, which went to fill the deficit in supply.

There are several items in the aggregate of coal in transit which will be discussed in turn.

No one knows how much coal is moving by rail or water at any given time. There is some evidence that normally it is something like the total output of the two weeks immediately preceding. If so, the quantity en route on March 1, 1922, would be 20,000,000 tons and the quantity en route on Sept. 1, 1922, 14,600,000 tons. The difference—5,400,000 tons—would have gone to fill the deficit. However far from the mark the factor of two weeks may be, it is clear that here is a source capable of supplying some millions of tons in the event of a stoppage of production. Failure to recognize this fact led to much loose thinking about the wastage of consumers' stocks last summer.

Coal on the Lake Docks is considered as in transit because most of it must be shipped away from the docks before it reaches the consumer. It is the largest factor in the fuel reserve of Wisconsin, Minnesota, the Dakotas and northern Iowa. Between March 1 and Sept. 1, stocks on the docks dropped from 5,160,000 to 292,000 tons. The difference—4,868,000 tons—went to meet current consumption during the period of the strike. In the month of September receipts by the lake receivers so far exceeded shipments that their stocks increased to 1,581,000 tons on Oct. 1. In spite of the increase the stocks are lower than at the corresponding season of any year covered by the published record. In comparison with 1921, when stocks were unusually heavy, they show a decrease of about 7,000,000 tons. The following statistics are supplied by courtesy of the Northwestern Coal Dock Operators' Association:

BITUMINOUS COAL STOCKS AT UPPER LAKE DOCKS*

(In Net Tons)

August 1, 1921	8,188,639	March 1, 1922	5,160,452
November 1, 1921	8,824,297	September 1, 1922	292,140
January 1, 1922	7,150,654	October 1, 1922	1,581,391

* These figures are exclusive of coal on private docks of industrial consumers, which coal is included in the consumers' storage.

The quantity of soft coal in cars at tidewater, Lake ports, the New England gateways or other junction points on Oct. 1 was not abnormal.

The strike of 1922 showed that the accumulation of loaded cars unbilled at the mines may at times be a factor of some importance in the above-ground reserve of fuel. When the strike began there were 1,530,000 tons of bituminous coal in unbilled loads; when it ended there were only 20,000 tons. The difference—1,510,000 tons—went into consumption during the stoppage. The following statement of average daily coal loads unconsigned covers all important carriers, and is furnished by courtesy of the American Railway Association:

Week ended	Unbilled Cars of Bituminous	Equivalent In Tons
March 4, 1922	14,126	700,000
April 8 (highest)	30,730	1,530,000
August 19 (lowest)	412	20,000
September 2	1,305	65,000
October 1	1,535	77,000

The number of bituminous operators who store their product is very small, but is apparently increasing. A careful inquiry by the Geological Survey last March, before the strike began, showed a total of 753,000 net tons in producers' storage. Of this 502,000 tons was at or near mines in southern Illinois, central Pennsylvania, West Virginia (particularly Logan County), eastern Kentucky, Virginia, Tennessee and Alabama. The remainder—251,000 tons—was stored in yards at intermediate points.

DAILY AVERAGE OF BITUMINOUS COAL IN HANDS OF VARIOUS CLASSES OF CONSUMERS, JULY 15, 1918, TO OCT. 1, 1922

(Figures represent number of days supply based on current rate of consumption at time of stock-taking.)

Illinois and Indiana Producers Decline Invitation to Cut Domestic Prices

Chicago, Ill., Nov. 6.—The conferences in Chicago last week which Fuel Distributor Conrad Spens held with both Indiana and Illinois coal producers did not produce quite the effect Mr. Spens hoped for. His suggestion that lump prices be dropped from $5@$5.50 down to about $4 was refused frankly by Indiana men, who declared they could not agree to such a thing for fear Federal Judge Anderson in Indianapolis would swoop down on them again for price fixing. Illinois men made no written answer but are giving Mr. Spens the unmistakable impression that they cannot agree to reduce prices a bit. However the continuance of warm weather which followed the public announcement that Mr Spens was trying to cut prices so softened the domestic demand that there were signs of shaved quotations in the Midwest markets. The principal southern Illinois producers stuck to their previous lump price of $5.50, central Illinois did its best to stay above $4.75 and Indiana coals that had been selling for $5 and $5.25 were held right there, with only occasional variations.

The whole Midwest is counting on a cold snap to remedy the present strained situation.

When Mr. Spens suggested that reducing the price from $5.50 to $4 would be a satisfactory thing for the producers of the Midwest region to do, the general reply was that since mine costs had mounted 50 per cent or more with the 50 per cent or greater drop in car supply, domestic sizes were the only salvation of the coal business. If it costs almost $4 today to produce a ton of coal in Illinois, and more than half the coal produced is screenings and must be sold at a considerable loss—say at $2@$2.25—it was advanced to Mr. Spens as obvious that a maximum of $4 could not be fixed for lump or the business of coal mining would collapse amid a large puff of bug dust.

When the point was raised that West Virginia had cut the price from $7.50 to $6, thus apparently arguing that Western mining companies should effect a similar reduction, there was no hesitancy in asking if Illinois and Indiana are now to be penalized for not setting their prices up to $7.50 at the end of the strike. A hint that Mr. Spens has power to shut off car supply to recalcitrant Western mines and can permit amenable West Virginia mines to have enough cars to flood the West with competitive coal did not scare the Westerners. The attitude of many of them was: "We're ready to do battle in the courts any time cars are shut off, and anyway West Virginia isn't in position to flood the West with coal even if it got all the cars in the United States." Mr. Spens could not set a minimum price, so the operators would not set a maximum.

While the conferences at Chicago bred little ill feeling, thanks to Mr. Spens' tact and good judgment, they did not make much progress and it is understood among Western coal men that the Fuel Distributor is disappointed. The feeling among them is that a good stiff cold snap would go a long way toward relieving the tension.

Expert observers feel that Mr. Spens' activity at Chicago will have a wholesome effect. It at least gave the government a chance to indicate that it can take a hand if prices do any ground and lofty tumbling, and this is expected to have a restraining influence even if a cold snap comes down and sets the domestic market all agog.

Washington, D. C., Nov. 3.—Results of a conference between Federal Fuel Distributor C. E. Spens and a delegation of coal operators from the northern West Virginia bituminous field, at which a reduction of $1.25 per ton in the maximum price of domestic coals mined in this field was arranged, are given in the following statement, issued today by Mr. Spens:

"A conference was held in Washington, Nov. 2, between the coal operators of the northern West Virginia field, which includes the Fairmont district, and the Federal Fuel Distributor, to discuss the question of maximum prices f.o.b. at mines on prepared sizes of bituminous coal for household purposes.

"The operators signified their willingness not to exceed a maximum f.o.b. price at mines of $4.50 per ton. Previous prices having ranged as high as $5.75 per ton, the new basis, therefore, constitutes a reduction in the previous maximum figure of $1.25 per ton. This basis was voluntarily established by the operators in the northern West Virginia field in recognition of the present emergency and to assist the Federal Fuel Distributor in the accomplishment of the purposes of the act establishing this office."

Spens Urges Anthracite Producers to Help In Elimination of Speculation

Producers of anthracite have been requested by Federal Fuel Distributor C. E. Spens to market their coal only through legitimate trade channels, in order to eliminate intermediate speculation, which has tended to increase unduly the price of hard coal in some sections. Mr. Spens' communication, addressed to all hard-coal operators, under date of Nov. 4, is as follows:

Complaints are reaching the Federal Fuel Distributor from a great many sources that higher f.o.b. mine prices than those already agreed upon with the Fair Practices Committee of Pennsylvania as basic mine prices are being asked on anthracite coal, and investigation has developed that this is due to a great extent to the employment of too many intermediate channels between the producer and the consumer.

This condition of affairs can largely be corrected by the producers themselves, by confining their sales to legitimate wholesalers and to legitimate retailers who deal directly with the ultimate consumer.

In view of the current 'normal' level of anthracite prices and the intense demand due to anticipated reduced production, "intermediate speculation" savors of cruelty, and the Federal Fuel Distributor invites the co-operation of all producers to the end that the activities of this parasite on normal exchange may be entirely eliminated or at least be reduced to a minimum.

The continuance of such practices reflects on the entire anthracite industry, which is most unfortunate, since so large a proportion of the representation of that industry is cooperating with all interests in a splendid manner in coping with the present emergency.

Blast Entombs 90 Miners at Spangler, Pa.

An explosion in the Reilly Mine of the Reilly Coal Co., at Spangler, Pa., early Monday morning, Nov. 6, entombed between ninety and ninety-five miners who had gone to their work shortly before. The extent of the explosion has not yet been determined, but at the office of the company, it was said its effect was "pretty bad."

The mine rescue section of the Bureau of Mines at Pittsburgh ordered a rescue car to proceed to the mine without delay. Another car, which is now in New York State, also was ordered to Spangler.

The Reilly Mine is a shaft some 500 feet deep, and normally employs about 120 men. It is owned by the Joseph H. Reilly Coal Co., of Philadelphia, and produces about 125,000 tons a year.

Bituminous Operators About to Draft Suggestions to Coal Commission

A draft of the suggestions which the National Coal Association will make to the President's coal commission as to the scope of its work will be considered by the committee headed by J. C. Bryden at a meeting to be held in Washington, Nov. 9. While no information is available as to the specific recommendations which the operators' committee will make, it is known that they will ask only for the consideration of the broad questions involved rather than suggesting the investigation of detailed matters, which obviously would consume more time than is at the disposal of the commission. The members of Mr. Bryden's committee are J. G. Bradley, L. W. Galkin, Michael Gallagher, H. N. Taylor, George Herrington and E. C. Mahon.

The anthracite operators have as yet made no formal reply to the request of the coal commission for recommendations, although it is unofficially reported that they too are considering the draft of a letter to the commission on this subject.

Federal Income Tax Returns in Relation to Investigation of Operators' Profits

[The information in the law covering the Hammond Coal Company case profits of the coal operators for the past two years by investigators has caused many to turn to the records of the Internal Tax Bureau of the Treasury at Washington in the belief that here will be found the data desired and required. The following is a brief summary of the rulings on the laws of the past two years so they may have a bearing on the value of those figures, as far as comparisons is concerned.—EDITOR.]

With respect to gross income the tax blank for 1913 permitted the profit from the sale of capital assets, if acquired prior to Jan. 1, 1909, to be prorated over the period from date of purchase, levying a tax in the year sold, on the amount accrued since 1909. Subsequent laws fixed the profit as the difference between the "fair market value" at March 1, 1913, and the selling price, if the property was acquired prior to that date. The 1921 law places a maximum tax of 12½ per cent on capital gains.

Under the 1913 tax law dividends received were taxable at the rate in effect on other income. The 1916 law taxed dividends in like manner, when received or ordered to be made. The 1916 and the 1917 laws both specifically attempted to tax stock dividends, if paid out of surplus accrued subsequently to 1913. The 1917 law taxed them at the rates of tax in force in the period when earned, or in lieu thereof at the rate of 2 per cent. Under the present law the dividends received by corporations are not subject to income tax.

Deductions Allowed in 1917 to 1916

The tax blanks for the years 1913 to 1916 provided for deduction of "only the ordinary and necessary expenses paid within the year in the maintenance and operation of the business and properties of the corporation," and went on to specify that "all expenses of material, labor, fuel, and other items entering into the cost of goods purchased, sold, or manufactured are deductible under the head of expense." The 1917 form provided, as did the others, that expenditures for incidental repairs which do not add to the value or appreciably prolong the life of property are deductible as expenses. The 1917 law uses the words "all the ordinary and necessary expenses paid" within the year.

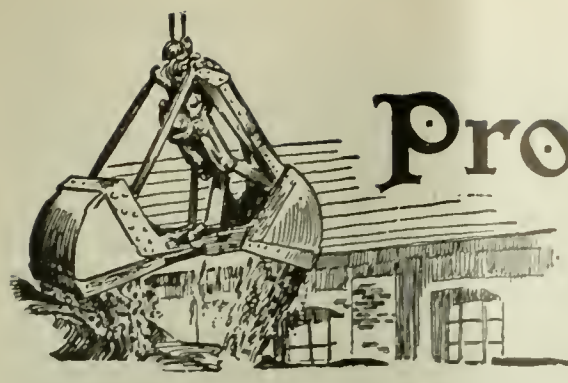
The 1918 law reads "paid or incurred." With the issuance of Regulations 45 covering the law of 1918, the Income Tax Bureau gave recognition to the peculiar conditions surrounding the mining industry, and in Article 222 of the Regulations set up the specific test that in a developed mine, where the minor item of plant and equipment purchased or installed would increase production, its cost might be treated as an item of expense. Specific examples were cited as "mules, mules, mine cars, trackage, cables, trolley wire, fans, small tools, etc., necessary to maintain the normal output because of increased length of haul or depth of workings consequent on the extraction of mineral."

This regulation was issued by the Internal Revenue Bureau at the urgent request of the mining industry. It served as a guide for the field examiners and auditors of the department, and promoted generally the accounting methods which had been in vogue with conservatively operated companies in preceding years. It also gave recognition to the basic differences between the mining industries and others, as manufacturing and railroad operation. In the examination of the 1917 returns by the field men of the Internal Revenue Bureau innumerable controversies had arisen with the taxpayer as to the treatment of the class of articles enumerated in Article 222, the agent of the government insisting that they be capitalized, while the taxpayer insisted that proper accounting required them to be treated as items of expense. This regulation settled the controversy so far as 1918 and succeeding years are concerned, for while the wording of the regulation was afterward revised, the principle established still holds. Since the 1917 and the 1918 laws are practically identical as to what constitutes allowable expenses, it naturally follows that the taxpayer is entitled to the same allowances for 1917 as for 1918.

All of the revenue laws have made allowances for losses actually sustained and charged off, but the law of 1921 allows "at the discretion of the commissioner, a reasonable addition to the reserve for bad debts."

The 1913, 1916, 1917, 1918 and 1921 tax laws all provide for allowances which fairly measure the loss during the year of physical property by reason of exhaustion, wear and tear—that is to say, depreciation. The earlier laws specified that it should be based on *cost*. With the issuance of Treasury decision 2,754, on Aug. 23, 1918, recognition is given to the principle that depreciation on property purchased prior to March 1, 1913, might be figured on the fair market value at that date instead of on the basis of cost.

With the issuance of the regulations for the year 1918, recognition also was given to the method used by many mining companies of calculating depreciation on the basis of the tonnage exhausted, at a rate per ton obtained by dividing the capital sum invested in plant and equipment by the total number of tons recoverable from the acreage assigned to a given mine, thus giving a unit value per ton as a measure of depreciation. The option also was given to the taxpayer to add the values of plant and equipment to the value of the mineral and development and to make a composite deduction for depreciation and depletion.



Allowance for Depreciation Allowed in 1916 Law

The 1909 law did not allow deductions for depletion. With the passage of the 1913 law recognition was given in part only to the loss to the mining company by reason of the mining out of the mineral, and deduction for depletion was allowed "not to exceed 5 per cent of the gross value at the mine of the output for the year." With the 1916 law full recognition is given to the right to depletion allowances based on cost or the fair market value at March 1, 1913. It is a fact that because of the low tax rate under the 1916 law and the trouble and expense incident thereto, few coal operators took advantage of the privilege of placing a value on their mineral at 1913 and continued to make deductions on the basis of cost. With the high rates under the Income and Excess Profits Tax laws of 1917 an additional number of taxpayers accepted the opportunity to revalue, but because of the difficulty of finding a basis on which real values could be proved many have not yet obtained the values to which they may be entitled. In the period preceding 1913 few coal properties changed hands, and not until the acceptance by the Internal Revenue Bureau of the principle of fixing values on the principle of the "present value of eventual earnings" has it been possible to gain much from this provision.

There seems to have been no doubt as to the right of the taxpayer to amortize the cost of obtaining a lease under the laws passed prior to 1918, but not until the passage of that act has he had the undisputed privilege of valuing a leasehold at March 1, 1913, for the purpose of depletion. At the present time comparatively few coal operators in some states have such values to the satisfaction of the Commissioner of Internal Revenue and have therefore not gotten the value of this deduction, although such values may be very substantial and much in excess of the lessor's interest.

Prior to 1918 interest deductions for the purpose of the income tax were limited to the amount actually paid on bonded and other indebtedness not in excess of the paid-up capital stock, plus one-half of the interest-bearing indebtedness outstanding at the close of the fiscal year. This restriction has been removed. With the 1918 law all interest is deductible, except that to carry obligations on certain tax-free obligations of the United States. It is also permissible to make deductions on the basis of interest accrued, which under former laws was not permitted.

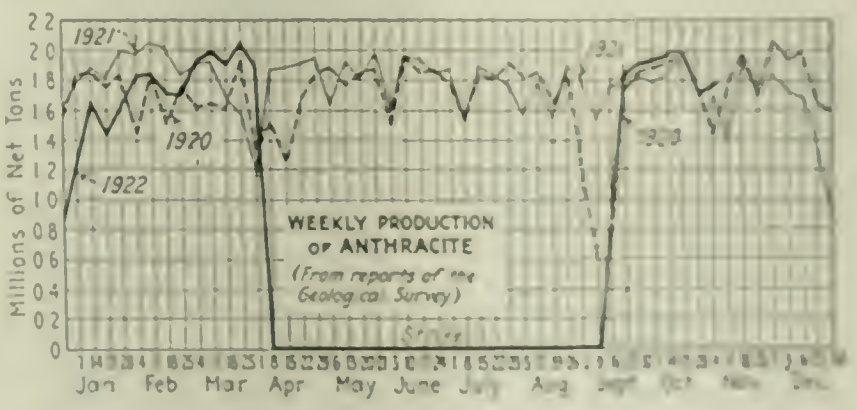
Under the laws prior to 1917 federal income taxes were an allowable deduction in making a return to the Internal Revenue Bureau. The deductions were required to be on the basis of actual payments. With the 1917 law, however, the federal income and excess profits taxes were no longer an allowable deduction, but with this year permission was given to the taxpayer to accrue other taxes upon his books as a basis of deductions.

Production and the Market

Weekly Review

Despite steadily increasing production the spot market indicates signs of firmness. Current offerings are being absorbed quietly and as production is now above current consumption it is apparent that the general run of consumers are accumulating reserves. Because of contract and railroad requirements the meager car supply permits little increase in the volume of spot coal and the gradual re-entry of buyers has further checked the descent of prices.

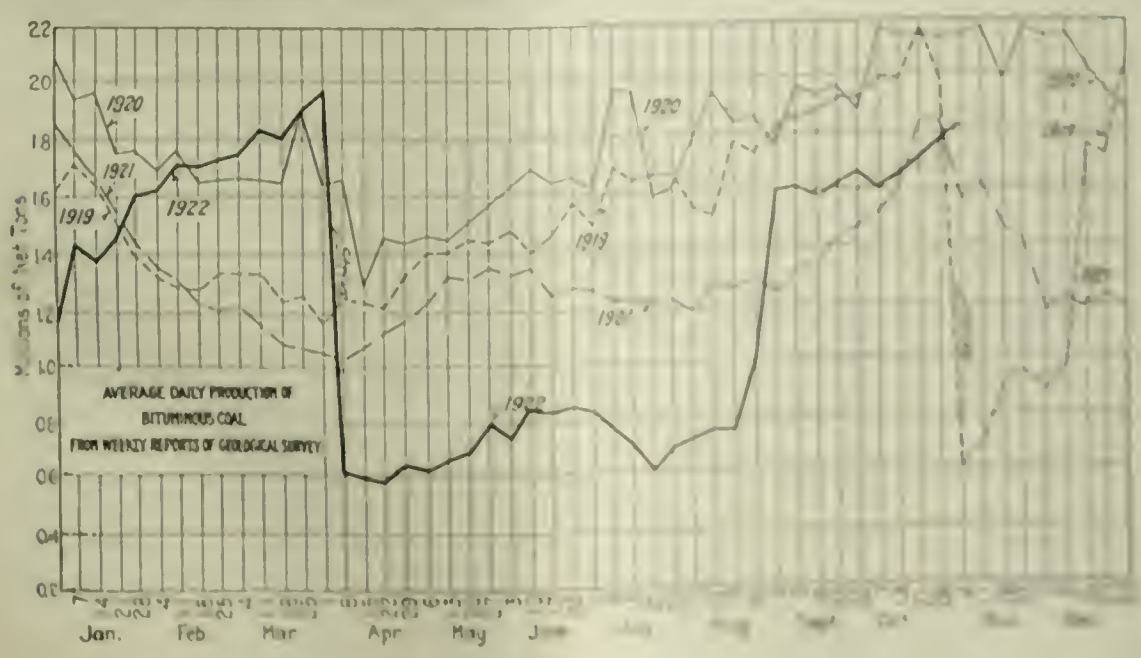
Coal Age Index of spot bituminous prices was 344 on Nov. 6, as compared with 346 on the previous Monday. This corresponds to an average mine price of $4.16, a decline of only 3c. in the week as compared with a drop of 7c. in the previous week and 19c. in the seven-day period just preceding. High-grade coals are scarce and prices are firmly held.



Present Situation a Reversal of 1917 and 1920

Market conditions are the easiest in the North Atlantic and New England section. The situation today is just the reverse of 1917 and of 1920, when Eastern industrial activity taxed rail facilities to the utmost to provide much-needed fuel. Eastern coal stocks are not heavy but there has been such an influx of British fuel and the coastwise trade has been so active that this market is comparatively weak.

Heavy Lake shipments and a healthy Western demand have resulted in congestion at the various gateways. An embargo on the westward movement of C. & O. coals, which lasted for a week, failed to clear this congestion, but instead choked mine sidings with the current week's loads which could not find a ready market in the East. Movement through the Cincinnati gateway is now stupendous, but the three carriers are hard pushed for cars because of the slow return of empties.



Domestic demand is still the most attractive for Middle Western fields. So much prepared coal is being made that the resultant sizes are a drug on the market. Ohio's law fixing a maximum price on coals mined and sold within that state caused such a heavy movement to other markets that the fuel authorities called a conference of producers last week to remedy the situation. Although no formal announcement was made following the meeting it is understood that the operators promised their co-operation in providing tonnage within the state, thereby avoiding the necessity of longer hauls from other producing fields.

The Northwestern territory will need approximately 3,000,000 additional tons of Lake coal before the close of

navigation. With dumpings at the lower ports being maintained at their present rate it is expected that this program will be accomplished. All-rail coal from Indiana, Illinois, etc., will of course be drawn on more heavily for this section during the winter than in normal times. Federal Fuel Distributor Spens believes that by Nov. 15 the peak of the autumn movement of grain and other commodities will have passed, thus releasing more transportation for coal.

Many buyers are relying on the close of the Lake season to release a flood of coal and weaken the price. It is not unlikely, however, that their entry into the spot

Estimates of Production

BITUMINOUS

ANTHRACITE

COKE

market at one time will offset any top-heavy market conditions.

Retail demand for anthracite is pressing. Dealers are behind in their deliveries and are urging consumers to accept substitute fuels, at least for immediate needs. The Lake program is being given preference, but this tonnage must be supplemented by a considerable all-rail movement to safeguard the Northwest's requirements this winter. Dumpings at Buffalo last week were 94,200 net tons, as compared with 120,500 tons in the preceding week. High independent quotations are now rarely heard, as dealers hesitate to pass on excessive premiums to their customers.

The steam sizes of anthracite are still heavy, although buckwheat is better taken on account of the shortage in domestic grades. Rice and barley are still soft and producers, wherever possible, are running these coals to storage.

BITUMINOUS

"Preliminary returns on coal production in the week ended Nov. 4 indicate a total of 12,481,000 net tons of which about 10,700,000 tons is bituminous coal and 1,800,000 tons is anthracite," says the Geological Survey. "Revised estimates for the fourth week of October show 10,681,000 tons of bituminous coal and 1,773,000 tons of anthracite. Thus a slight increase in the total coal raised is shown for the present week as compared with the week before.

"The increased rate of production during the past three weeks is due principally to improvement in transportation, which is reflected in the reports on operating conditions summarized in this review and also by revised figures of loading for the week Oct. 23-28, which show that following the Monday-to-Tuesday drop the rate of loading declined less from Tuesday to Friday than in earlier weeks."

Despite reassuring statements from the Department of Commerce and from the Federal Fuel Distributor, representatives of the public utilities contend that the coal situation, so far as their plants are concerned, is getting worse instead of better. The figures of the American Railroad Association also are attacked as being inaccurate. The belief held in public-utility circles is that there are duplications in the figures as to car loadings. Since the utilities are hampered by fixed incomes in bidding for coal against manufacturers, they believe nothing short of the re-establishment of priority No. 2 will enable them to build up the reserves necessary to carry them through the winter.

Eastern and Middle Western utilities have been asked to await the closing of the Lakes before attempting to build

* Net tons, f.o.b. mines. † Advances over previous week shown in heavy type, declines in *italics*.

Coal Age, Index 344, Week of Nov. 6, 1922. Average spot price for same period, $4.16. This diagram shows the relative, not the actual price on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions each of slack, prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

up storage. They contend, however, that the closing of the Lakes means that freezing weather has arrived and a tonnage far in excess of that moving up the Lakes will have to be delivered to domestic consumers. Moreover, the advent of cold weather means that the railroads are 20 per cent less efficient.

The point on which the public utilities are placing most emphasis is that deliveries on their contracts frequently are as low as 15 per cent, while in only rare instances are they exceeding 50 per cent. The high prices being paid for coal in the Middle West have unbalanced the transportation movement from Eastern mines and this situation is further

How the Coal Fields Are Working

curtailing the chances of the public utilities to obtain reserves sufficient to insure the proper margin of safety.

All rail shipments to New England declined to 2,880 cars during the week ended Oct. 28 as compared with 3,602 cars in the preceding week. Strenuous efforts are necessary to place this tonnage as competition from the coastwise trade is very keen.

Hampton Roads dumpings were 214,874 net tons during the week ended Nov. 2, the lowest since early last January and 80,000 tons less than in the previous week. Only the C. & O. piers registered any gain in dumpings. Tidewater prices are weak but the meager offerings have prevented much of a drop.

During October 2,688,924 net tons of soft coal and 267,744 tons of anthracite passed through the "Soo." Dock supplies of bituminous are piling up as consumers are slow to place orders. The southern end of the dock territory is being canvassed actively by all-rail shippers who need an immediate outlet for their top-heavy storage stocks, produced in an effort to meet the domestic demand.

ANTHRACITE

Production of anthracite was reduced by the observance of holidays during the last two weeks. The output for the week ended Oct. 28, was 1,775,000 tons and for last week approximately 1,850,000 net tons.

Domestic demand is pressing and dealers make only partial deliveries, urging consumers to use substitute fuels wherever possible. Every effort is being made to push the Lake program but it is apparent that considerable all-rail tonnage will have to be shipped to take out the Northwest's winter requirements.

COKE

Production of beehive coke was 330,000 net tons during the week ended Oct. 28 as compared with 310,000 tons in the preceding week. The principal increase was in the Connellsville region. That market has retained its strength and some last-quarter business has been done. Consumers appear satisfied with the recent decline in price and many of them are covering for the balance of the year.

Foreign Market And Export News

British Prices Gain Strength. Output Makes New Record: French Market Improves

Heavy production of British coal has followed a more satisfactory market. The output during the week ended Oct. 21 was 5,555,000 gross tons, according to a cable to *Coal Age*. This is the highest week's production since 1913 and is 100,000 tons in excess of the preceding week's output. Prices are strong on all good grades.

The South Wales Miners' Federation has decided to withdraw its notice of a general strike, and work in the mines will be continued. It was found that only a small percentage of the miners were obeying the call, which was issued to force complete nationalization of the mine fields.

In spite of the threatened labor trouble in Wales the pits there continue to be well booked up. The United States orders are naturally still falling off but these are compensated for by increased demands from South America and Europe, while Canada's inquiries are on the increase. The coal industry in northern England is stronger. In many cases the pits are booked up over November, and in some instances in early December. The result of these circumstances has been a further advance in prices which has led Continental customers to hold off awhile. In general it may be said that the Northumberland and Durham markets are firmly established up to the new year.

The Scottish trade with Europe continues to be good and it is thought that a large share of the contracts for Swedish State railway coal will be taken in Fife. Industrial and domestic demand is poor.

French Collieries Flooded with Domestic Orders

Nord and Pas-de-Calais collieries report in a favorable position. Industrial demand is, on the whole, satisfactory. Collieries are flooded with orders for domestic coal—owing partly to the failure of Belgium to provide the market with adequate supplies.

The situation of the Loire and Center fields is quite good for domestic and is improving for industrial coals. Production in the Sarre and Lorraine fields is increasing, with a comparatively easy outlet. The output of the Sarre mines in August was 1,019,000 metric tons, with stocks at the end of that month amounting to 545,000 tons. In August, 187,000 tons were sent to Germany.

The French Higher Railway Board has decided that in the general revision, railway rates will have to keep within a maximum limit of three times the pre-war transportation costs. At the same time it fixed May 1, 1923, as the latest date by which the revision should be completed. Coal rates will, of course, be included in the general revision of the schedule.

Hampton Roads Pier Situation

	Week Ended Oct. 26	Week Ended Nov. 2
N & W Piers, Lamberts Point:		
Cars on hand	937	571
Tons on hand	60,322	32,993
Tons dumped	96,335	66,117
Tonnage waiting	13,875	28,950
Virginian Ry. Piers, Sewalls Point		
Cars on hand	725	723
Tons on hand	46,650	43,250
Tons dumped	110,823	84,748
Tonnage waiting	7,149	26,443
C. & O. Piers, Newport News:		
Cars on hand	348	422
Tons on hand	17,400	21,100
Tons dumped	54,057	40,887
Tonnage waiting	250	1,470

Hampton Roads Supplies Dwindle

Short supplies, with extremely dull business, featured the week at Hampton Roads. Stocks were dwindling to the lowest point in the year while dumpings were also at a low ebb.

The low supply narrowed the price range and put temporary strength in quotation. The tonnage awaiting cargo neared the level of stocks at the piers.

The steamship Arcadia cleared for Oran during the week with 3,965 tons cargo.

Coal Paragraphs from Foreign Lands

GERMANY — Ruhr production was 1,959,000 metric tons during the week ended Oct. 21, according to a cable to *Coal Age*, as compared with 1,972,000 tons in the previous week.

BELGIUM — The coal market is still very firm. Consignments are in full swing for domestic consumption. Sized kinds and anthracite are high and difficult to obtain. Industrial sorts find a ready sale either to the home iron and steel works or for export.

Much feeling has been aroused in industrial circles by a decision of the Joint Committee to raise miners' wages by 8 per cent. The owners have announced a corresponding advance in the price of Belgian coal, while German fuel supplied under the Treaty of Versailles has been increased in price by about 10 francs for all qualities.

INDIA—On the Bombay coal market few transactions are being carried out and the market does not show a firm tendency. Stocks are sufficient. The prices are: Bengal first, Rs.28; good second, Rs.26@Rs.27; English coal, Rs.38; African, Rs.27½.

AUSTRALIA — Considerable improvement has been noticeable recently in the coal trade in New South Wales, and the export business recorded during August was 60,000 tons better than that of July, and nearly 70,000 tons in advance of the June figures. One of the most pressing problems facing mine proprietors is the difficulty of disposing of the stocks of small coal.

Firmness Pervades Market Due to Meager Car Supply

Big Buyers Prevent Further Price Slump—Receipts Readily Absorbed, Though Average Consumer Bides Time — High-Grade Coals, Now Scarce, May Disappear with Seasonable Weather.

Extremely poor car supply kept the market firm last week. Big buyers are all that hold prices from slumping further. The light receipts are, however, absorbed with but little difficulty, but the average consumer is content to rest on his oars. Some of them have accumulated sufficient reserves to enable them to await heavier receipts, which it is felt will soften the spot market.

High-grade coals are very scarce. Any seasonable weather will hasten their disappearance from the market. Southern coals are moving in slowly and British receipts are now only occasional. Much complaint is heard from the mines over poor commercial loading time, while railroad fuel loadings are being given preferential car supply, it is asserted.

PHILADELPHIA

The consumer continues to be perfectly satisfied under present conditions, while the producer complains that the limited production makes mining extremely expensive at present prices.

Everyone still talks of shortage of cars, although some roads take exception to this statement, and maintain that the market is being well taken care of. The transportation lines point out that they are carrying the heaviest tonnage of general freight for many years and that coal shippers cannot expect to get all the cars.

The big buyers continue to be the railroads, steel plants and power concerns, and it is this buying that is keeping the market up. Quite a few of the private plants have already accumulated supplies in excess of normal, although the railroads are much behind.

The best market has been in the high-grade coals, with Pool 1 very scarce. While Pools 9 and 71 are in better volume the prices at this time are inclined to become a trifle more firm.

The steamship Nordfarer cleared for Havana last week, the first cargo in some time.

NEW YORK

There has been a slight improvement in the Tidewater market and more activity exists in the line trade. At times the improvement has been reflected in the quotations but the market is still spotty.

Buyers showed a little more interest but were cautious about placing orders. In some quarters quiet buying is reported which has been spread over considerable territory. In this manner it is thought many consumers are better prepared for the future than is generally known. The railroads have taken good care of themselves, contracts being reported under $3 for assigned cars.

There were at the local terminals on Nov. 2, 1,489 cars of coal, nearly all of Pools 9 and 10. This was approximately 500 cars less than there was on hand the first day of the week.

Producers report a better demand from New England for Pennsylvania coals after strong efforts made to regain some of the business lost to Southern coals during the strike. In this market Southern coals are being received in smaller quantities while British coals are arriving only occasionally.

Pittsburgh gas run of mine was quoted locally $4.50@$4.75 and lump, $5 @$5.25 early in the week. Other quotations included Shawmut district around $3.25; Allegheny Valley, $3.30; B., R. & P., $3.25; Westmoreland gas, $4.15; Westmoreland slack, $4.75, and Broad Top smokeless, $4.50@$4.75.

CENTRAL PENNSYLVANIA

The car shortage is becoming more acute as cars are being diverted to the hard-coal regions. In many instances, even box cars are being sent east. On the other hand, but little coal is bought, the market being exceedingly dull. The output during the week ended Oct. 22, was 18,885 cars, against 20,249 for the week previous. At some places mines were without cars all week and in order to keep the men busy, large quantities of coal were being stored.

The lower grades are selling at $3@ $3.25, while Pool 10, which is extensively mined, ranges $3.25@$3.60; Pool 9, $3.50@$4, and Pool 71, $4@$4.75.

UPPER POTOMAC

Conditions in the Upper Potomac more nearly approximate normal in so far as production is concerned. In the Georges Creek field the strikers in certain sections such as Frostburg and Lonaconing are still holding out in the hope of forcing a recognition of the union. In neither region is the demand particularly stiff.

BALTIMORE

The striking feature of the market continues to be the light demand and the sliding scale of prices. This is made quite plain when it is pointed out that the average spot price of all grades of soft coal at the end of September was around $5, while the present price average is about $1.50 lower. There is enough coal at present to go around in easy fashion despite the poor run of cars, which has now been a feature for several weeks.

Some increased demand is noted from retail dealers who are persuading householders that they must burn soft coal in lieu of anthracite. This element is by no means heavy, however, and has not had any material effect on the price list, which is as low as it has been for a number of weeks past. The importation of English coal is not brisk at this point.

FAIRMONT

Transportation conditions appear to be improving slightly yet mines are hardly getting more than 25 per cent car supply, with those having railroad fuel contracts being given the preference. Lessened movement to Western markets because of additional embargoes only forced more tonnage to the East, and tended to soften prices. Not much coal was consigned to Western points except by way of the Charleston gateway and thence over the K. & M.

West

SALT LAKE CITY

Operators indicted by the district grand jury last week have appeared in court and given bonds. Individuals indicted are all well known in the industry. There is practically no public interest in the proceedings.

Vice-President Morgan Harper of the U. S. Fuel Co. told a *Coal Age* correspondent that the car shortage is worse now than he has ever seen it here. Mines are working around two days a week and this condition is almost entirely due to the car situation. There is a surplus of labor and men are being turned away every day. Operators are behind on their orders, but not hopelessly.

Some business is being done in California, Washington and Oregon, but no Utah coal is being placed on the Pacific. Railroads are buying for current use only. The local market has improved somewhat as a result of the cold snap but practically nothing is being done on storage orders, though many are still without their winter supply.

DENVER

The lack of production in Colorado, due to car shortage and railroad inability during the week ended Oct. 21, according to statistics compiled by operators here, amounted to 41 per cent or 87,605 tons. Mine capability for that period was only at the rate of 915 tons. Loss of production on account of no market was 14 per cent or 2,873 tons. The actual production amounted to 70.4 per cent or 118,147 tons.

In spite of the car shortage, production in Colorado from Jan. 1 to Sept. 30, 1922 shows an increase of 507,193 tons over the same period in 1921, there being 6,916,131 tons of coal mined thus far in 1922. Warm weather has softened the domestic demand though few consumers are ready for winter.

KANSAS CITY

Warm weather has caused a slump both in demand and price for some grades. Kansas nut coal is piling up at the mines and it is estimated that there are 400 cars of that grade awaiting orders.

Retail demand has slumped along with the wholesale, but steam coal is easier and demand for slack is holding up well when compared with other grades. Prices for Kansas are unchanged.

Anthracite

Operators Booked Way Ahead: Receipts Decline in East

Retailers Able to Fill Only Part of Urgent Demand—Lake Business Blamed—Independent Coal Offered Freely, but Dealers Are Backward in Ordering It.

Producers are heavily booked ahead. Eastern receipts are so low that retailers are unable to fill more than a portion of their urgent consumer demand. Lake business is given as the reason for the decline in Eastern movement. During October 595,100 tons cleared from Buffalo, but the movement is now declining.

Independent coal is more freely offered, but dealers are slow to place orders for the high-priced tonnage. Substitute fuels are not finding a ready market, thereby adding to the volume of unfilled anthracite business on retail books. Buckwheat is in somewhat better call, but other steam grades are slow and companies are still running to storage.

NEW YORK

There is an urgent domestic demand. Dealers—wholesale and retail—are being pushed for deliveries with the result that producers nearly without exception, are heavily booked ahead.

Consumers continue to insist upon receiving their regular coals, notwithstanding the shortage and the efforts being made to introduce the use of substitutes.

State Fuel Administrator Woodin issued an order on Oct. 27 and until further notice all egg, stove and chestnut coals dumped at the railroad terminals for delivery to dealers in Greater New York or arriving by rail at the dealers' yards shall be known as pebble coal and no delivery to any consumer shall be made from such coal in excess of one ton.

Quotations for straight lots of egg, stove and chestnut as high as $12.50 from some of the independent operators continue, although the latter believe this will be, as a rule, a couple of dollars lower.

Buckwheat is moving better but is comparatively weak. Rice and barley are flooding the market. There are reported to be more than 2,000 cars of these coals at the various terminals with more than 100 loaded boats in the harbor.

PHILADELPHIA

The amount of coal for delivery is even less than last week, and the yards are near the condition they were in during the summer. Quite mild weather having prevailed the consumers on the dealers list have lightened somewhat, but the movement is nevertheless greatly worried. There have been instances of late where retail men have actually locked their doors against would-be purchasers.

There is just the slightest hope that relief will be forthcoming a little earlier than Dec. 1, which latter date has been the usual time for the speeding up of deliveries to this market.

Many dealers are already taking in a little bituminous coal, as well as coke, and an even larger number have purchased a car or two of buckwheat. The consumer, however, when he is confronted with the fact that there is a shortage of anthracite now intimates that it is artificial and that everything will be all right soon.

Steam coal is little changed, although buckwheat may be said to have made some gains. Rice and barley are plentiful, and all sizes continue to be sold off company prices.

BALTIMORE

The fuel committee continues to take up a number of questions, especially along hard coal lines. One of the interesting situations of the moment in this regard has to do with a Pennsylvania operator who is said to have made offers by letter of coal at a price considerably above the maximum.

The situation of the hard-coal dealer is none too pleasant. More than 40 000 families are still without coal and the complaints that are pouring in are of a strenuous nature. Dealers say that it is hard to deal with some of their old-time customers who think they should be given preferential treatment, and who insist upon having hard coal. A number of the dealers have gotten down to the delivery of one-ton lots and are far from getting around the circle of their customers even on that basis. Coal is coming in at the rate of about 3,500 tons per day, with a shortage of over 250,000 tons to meet.

BOSTON

Householders are still proceeding comfortably on the assumption that somehow they will have enough coal to keep them warm through the winter. Receipts are discouragingly low, especially by the all-rail route, and retail dealers who have not been able to make one-ton deliveries on more than a fourth of their orders are wondering what will be the outcome.

At wholesale production lags notably. A succession of miners' holidays is one cause, and a developing car shortage is another.

BUFFALO

The supply is coming in so slowly that consumers are in despair. Dealers are wondering how they are going to stand the pressure when cold weather sets in.

Lake movement is rather light although for October the loading was 797,100 net tons as compared with 794,400 tons last year. Last week loadings were 94,200 tons, of which 47,400 tons cleared for Duluth and Superior; 3,000 for Hancock; 600 for the Soo; 17,500 for Milwaukee; 6,200 for Escanaba; 7,500 for Chicago, and 12,000 tons for Green Bay. Freight rates are 40c. to Duluth; $1 to Hancock and the Soo; 50c.@60c. to Chicago; 50c. to Milwaukee and Green Bay, and 55c. to Escanaba.

Coke

CONNELLSVILLE

The market is fully as strong as a week ago, from the price view-point, and a close analysis might show it a shade stronger. Distress coke, on track and requiring to be moved, goes at about $7.50, while for shipment over a few days or more the market is steady at $8.

Current buying appears to be light, while production has been increasing continuously. Prevention of further decline appears to have occurred by a number of furnaces concluding to buy to the end of the year on the drop from $12 to $8, not waiting for any further decline, and insuring themselves against an advance in December, which might occur on account of railroads being affected by bad weather.

The pig iron market is very dull and it seems improbable that any more idle furnaces will go into blast in the near future. Furnaces consider $8 altogether too high for coke, when they have difficulty in selling pig iron at $30 and have to make iron on old orders at considerably less. Foundry coke remains at $10 to $11, with only a moderate demand.

The *Courier* reports production during the week ended Oct. 28 at 109,110 tons by the furnace ovens and 50,670 tons by the merchant ovens, a total of 159,780 tons, an increase of 13,060 tons.

UNIONTOWN

Clearing up of congestion at the Lakes together with a railroad jam in the Eastern market were responsible for a stiffening of both the Eastern and Lakes market this week in the Connellsville region. As soon as the jam at the Lakes was relieved buyers there commenced sending orders into the region.

A quick coke market with a slipping price has tended to absorb much of the surplus furnace tonnage to the point now where coke is again becoming scarce. On top of that is renewal of contract negotiations, the first of any importance this year, indicating that some furnaces at least prefer to have their fuel supplies come in regularly than to take chances on a temporary advantage in spot sales.

Steam coal is quoted at $3@$3.50 and byproduct, $3.50@$3.75.

The strike situation remains unchanged. The union is continuing the erection of barracks at the various coke plants replacing the tents occupied by strikers during the summer.

BUFFALO

Coke is not active so far as the big smelting trade is concerned and is quoted by jobbers at $10@$10.50 for foundry, $9.25@$9.75 for furnace and $7@$7.50 for odd grades. The local byproduct plants are increasing their oven activity on account of the domestic demand, selling their screened product at $12 at the ovens.

Chicago and Midwest

And Now Domestic Sizes Lose All Their Buoyancy

Producers Decline to Drop Prices but Demand Slacks in Hope That Spens Will Lower Market—Nut and Egg Are Suffering with Screenings.

The main struggle going on all last week in this region was to prevent the slump of prices on domestic sizes. It cannot be denied that demand for domestic egg and nut and even for lump slacked off noticeably after Fuel Distributor Spens' visit to the Illinois and Indiana producers Monday and Tuesday, Oct. 30 and 31. He asked that domestic prices be cut. The producers of both states declined, but the market sagged anyway and the only thing expected to save it was a cold wind from the North.

Steam demand continued to be absent. Almost every car of screenings that was not shipped under an iron-clad contract had to be forced. Southern Illinois sank as low as $2.25 when it had to go on the open market though a good deal was shipped at as high as $3 on contract. Car supply did not improve in any field but the weakening of the market made it impossible, for the first time, for some of the fields to use all the cars that were allotted them.

Practically all the business the western Kentucky field gets is day-to-day trade, which is unsatisfactory. Lump there is quoted at $4.50 @ $5.25 but there is shaving of the price occasionally to get all the output started away from the mines. In eastern Kentucky a few big buyers, concluding that Jan. 1 will see the market upset, are beginning to contract for the entire output of certain operations from now until April 1, at a figure a little above the present mine run market.

CHICAGO

If the Chicago coal market was discouraging a week ago, now it is absolutely depressing. The visit of Fuel Distributor Spens and his public efforts to get domestic prices reduced by agreement among coal men has had the inevitable effect. Domestic demand, which was the only demand there was, has softened. Continued warm weather has noticeably slowed buying of big coal. People who were more or less of the opinion that prices would drop, now are assured of it—and another ten days of this warmth is certain to produce that result.

Up to the end of the week the principal Franklin County producers published no concessions on their lump price of $5.50. Central Illinois lump ranged $4.50@$4.90 whereas some of it had previously sold a little above $5, and Standard district lump had hard sledding at $4.25. Indiana lump maintained its level of the week before. Egg and nut sizes weakened some and screenings continued to be a sodden drug on the market.

A small volume of Pocahontas kept reaching here at $6@$6.25 and enough hard coal was in the market to supply a part of the demand, though most of this anthracite, as usual this year, is shipped here by one concern. Old line company mine prices on the larger sizes range $6.92@$8.25 but occasional shipments of independent coal average around $12.50@$13 with an offer on a small quantity now and then running much higher.

Trade in everything has been getting lighter day by day for the entire week. The coal fraternity is still watching the Northwest skyline and the weather reports for hopeful signs of a storm and coal such as drifted down into Utah and Wyoming. When it comes, they say, the abnormal coal situation will remedy itself in large measure.

ST. LOUIS

Buying of both steam and domestic is practically at a standstill. Contracts are being held up and almost no coal is moving except that which is forced in anticipation of lower prices. Dealers have a pretty fair supply on hand and in transit and are afraid of being caught in the event of a decrease. This same condition applies to the country.

A summing up of coal men's opinions here is that a price on southern Illinois domestic size will be somewhere around $4.25@$4.50. This would mean a cut of up to $1.25 under present prices. Figuring on the same basis, Mt. Olive for country shipments would be about $4 and for St. Louis shipments would range about $3. This is almost impossible. Standard, based on the proposed reduction in the price of southern Illinois, would be $1.50 under southern Illinois, which would be about $3 for domestic sizes.

Retail prices, Nov. 1, for sidewalk delivery, were: Standard, $6.75; Mt. Olive, $7.50; Carterville, $9.50; Anthracite, $15.50; Coke, $12.50; Smokeless, $14.

Anthracite receipts recently compiled show up to Sept. 30, 5,000 tons had been shipped to St. Louis; 1,500 tons were shipped the week ended Oct. 7 and 3,000 tons ended Oct. 14.

WESTERN KENTUCKY

The field is getting a slightly better car supply, due in part to shorter hauls, cars getting back to mines more rapidly, and due to the fact that repairs are being made to slightly disabled equipment more readily now that the railroad shops are speeding up.

October car supply ran slightly better than 36 per cent on the I. C., and about 24 per cent on the L. & N. This was a better showing than in September. Production has been maintained on car-supply basis.

It is reported that some western Kentucky production has been loaded out by water to Memphis and Southern river points, by loading barges one-third to one-half full, and using light draft towboats. With a very poor stage of water in the Ohio, river movement has been necessarily small.

General prices appear to be a little weaker, though best coals have held their own.

SOUTHERN ILLINOIS

Continued mild weather has prevented the speculative market that was expected about this time. While lump and egg from the Carterville field is moving fairly well, nut coal and screenings are barely moving and some mines are carrying no bills. The tendency is to put off buying until something definite is known as to what the Government is going to do about prices.

In the Mt. Olive district there has been a surplus of all kinds of coal the past week. One reason that domestic coal does not move is on account of hopper-bottom equipment. Steam is unusually slow. The Chicago market for this coal has been easy and very little is moving to Omaha and Kansas City. The situation in the Standard field is bad. Screenings are down to $1.25, while 2-in. lump has dropped from $3.75@$4 to $3.25 and the steam nut has gone as low as $2.50.

Railroad tonnage out of both the Mt. Olive and Standard fields is fairly good. Mt. Olive district screenings are holding at $1.50@$1.75, while Carterville are down to $2. There have been occasional breaks in the prices of other sizes, but as a coal the Carterville and Mt. Olive fields are maintaining their domestic prices pretty well.

Movement of coal out of the Standard field has been extremely bad on account of embargoes. The railroads are obliged to take the billing and then they just put the coal on a side track and there it stays.

LOUISVILLE

A considerable volume of day-to-day business is being handled and a little open business where jobbers are given instructions to ship all they can secure at bottom prices. It is reported that some of the larger consumers have been placing a few contracts for production of mines, or part production, to April of next year. Some producers are unwilling to contract, as they see a higher market later, but others are very uncertain concerning the market from January forward.

Some coal men at the present time are arguing that cold weather will create a big demand, and that prices will jump fast, and that neither mines nor railroads will be able to take care of demand. Others hold that when Lake movement stops it will force prevent shippers to the Lakes to look for business, and will result in much larger production of lump coal which will take care of domestic demand, while screenings will go a long way toward supplying industrial demand.

Most retailers have very little coal on hand and only about half the domestic stokers have laid in fuel winter supplies. Undoubtedly retailers are going to be in the market rather steadily this winter for practically everything.

Eastern Inland

Last-Minute Lake Business Checks Declining Prices

Good Dispatch at Lower Ports—Car Supply Only Factor Limiting Production—Domestic in Strong Demand—Ohio Producers Co-operate with Fuel Authorities.

Prices are decidedly firm. The end of the Lake season is in sight and last-minute orders have helped the market. Dumpings are proceeding steadily and dispatch at the lower ports is good. Car supply is the only factor limiting production and there is so little free coal available that the market appears quite active. Domestic is in strong demand and industrials are quietly taking all possible tonnage without creating a bidder's market.

Ohio coals show a wide range. Most of this fuel is going out of the state at figures in excess of Ohio's maximum prices. At a conference last week Ohio producers agreed to co-operate with the authorities who seek to avoid the confusion of replacing this tonnage from outside sources.

EASTERN OHIO

Operations during the week ended Oct. 28 were again diminished by car shortage. Output was less than any week since early September. Tons produced amounted to 254,000 or about 47 per cent of rated capacity. Production during the calendar year indicates that out of a potential capacity of 35,977,000 tons only 8,401,000 tons or 23 per cent have been mined. This transportation situation is now usually bad as it does average this field and the volume of output is limited solely by car supply.

With the modest quantities of free coal available, demand has been considerably in excess of the supply and the trade therefore quite active. However, the larger steam users are awaiting the closing of Lake navigation at which time it is confidently expected there will be a plentiful supply.

In the spot market prices are holding at the maximum figures set by the Ohio Fuel Administration. Only small quantities of Pocahontas here are reaching this section.

Receipts at Cleveland during the week ended Oct. 28 were the largest of any week during the past two years. Total receipts amounted to 1,265 cars, an increase of 248 cars over the preceding week. Of this quantity 1,020 cars were consigned to industries and 245 cars to retail yards. Weekly receipts for the past month closely approximate requirements.

It is figured that in order to take care of this season's program about 1,000,000 tons of Lake coal will have to be sent forward.

Receipts at the lower docks are averaging around 2,300 cars per day and loadings around 2,500 cars daily. The railroads had 8,871 cars at the Lake front on Nov. 1 and 4,800 cars in transit.

CLEVELAND

The market has turned definitely upward. Demand for industrial fuel is broker than for some months. There is still no sign of buying for stock piles, however. That hand-to-mouth buying still prevails is evident from the fact that dealers report numerous pressing inquiries for delivery within 24 or 48 hours. Such prompt delivery is difficult to obtain and as a consequence consumers are beginning to realize that they have stayed out of the market too long.

The car supply is still scarce and much Ohio coal has been going out of the state because of the low fixed prices. As a result of the intervention by Federal Fuel Distributor Spens Ohio operators have agreed to load more fuel for consumers within the state in return for the assurance of more cars. The approach of cold weather, however, is expected to increase the demand sufficiently to keep the market strong.

Prices are up on an average of 50c. a ton for most grades over two weeks ago. No. 8 ¾-in. is bringing $4.75 against $4.25 two weeks before. No. 8 slack is quoted at $3.50. Middle district mine run is quoted at a range of $3.50@$3.75; screenings are $3.50@$3.75.

Up to Nov. 1 a total of 14,000,000 tons of coal had been sent by Lake to the Northwest. This compares with 20,000,000 tons to Nov. 1 in 1921. It is expected that between 3,000,000 and 4,000,000 tons more will be shipped.

PITTSBURGH

Coal prices on the whole are decidedly firmer than a week ago and the market in general may be said to have advanced about 25c., with the exception of domestic. By agreement with the fuel authorities operators are limiting 11-in. domestic lump to $4.50 as maximum, which compares with $5.25 @$5.50 ruling early in September. In some quarters it is suggested that the stiffer attitude on other grades is due to the concession made on domestic.

Car supplies continue far below capacity, but are as good as at any time recently. There is a heavy movement of Lake coal with some purchases being made. The line trade appears to be well taken care of as to current consumption. There does not seem to be any disposition to stock coal at this time.

Steam is now quotable at $3.25@$3.50, this being for either Pittsburgh district or Connellsville coal of good grade. Byproduct commands $3.75@$4 or of fair grade. Both steam and byproduct are 25c. higher than a week ago. Gas coal has stiffened even more, good Youghiogheny commanding $4.50 for mine run and $5@$5.50 for screened, while the better Connellsville gas coal brings $4 or possibly $4.25 for mine run.

BUFFALO

Some shippers call the prices a little stiffer, some do not. It all depends on the temper of the consumer. At the same time the buying is fairly good. The number of sellers has increased considerably of late, here at least, and that gives the market a dull look.

Bad storms will, no doubt, stiffen up coal prices, but more cars will put the prices down. It is a stand-off which idea is to prevail. Only scarcity of cars has held prices up where they are. While there does not seem to be much coal moving that has not been sold, if shipments fail to come in the consumer will pay more for a quick shipment. Quotations are about 35@$5.25 for Youghiogheny gas lump; $4.75@$5 for Pittsburgh and No. 8 steam lump; $4@$4.50 for Allegheny Valley and all mine run; $3.25@$3.50 for slack. To this add $2.09 to Allegheny Valley and $2.24 to other coals to cover freight.

COLUMBUS

With comparatively warm weather still continuing there is a slight recession in the domestic trade and prices have started to weaken. Dealers' stocks have been gradually increased during the past few weeks and some are not buying any more coal until they have disposed of what they have on hand.

Retail prices are steady at former levels. Hocking lump is not plentiful as a large part is still going out of the state. West Virginia grades are selling around $10 delivered and Pocahontas even higher.

Steam trade is rather good. Prices at the mines are firm at state fuel administration levels with $3.75 the usual figure. Screenings are selling slightly lower than the levels provided by the administration.

DETROIT

With moderate temperatures continuing, buyers are not manifesting the degree of interest that jobbers believe is necessary. Bituminous coal is coming into Detroit in moderate supply, but the quantity arriving apparently just about equals the amount called for in the hand-to-mouth system of buying.

Most of the receipts are coming from mines in Ohio. Hocking lump and egg is quoted $5.65@$5.85; mine run is $3.75, nut, pea and slack, $3.35. Three-quarter lump from the Fairmont district is offered at $4.50; mine run, $4, slack, $3.50. Pittsburgh No. 8 ¾-in. is quoted $4.50; mine run, $3.75; slack, $3.40. Four-inch domestic lump from West Virginia or Kentucky is held at $6.25, with egg at about the same price; mine run and slack are $4.

No improvement has occurred in anthracite supply. Shipments are equal to perhaps one-third of the normal daily requirements.

NORTHERN PANHANDLE

Mines were somewhat handicapped by the difficulty of getting coal through the Holloway yards of the B. & O. but with other outlets available Western and Northern shipments were not affected to the same extent as in other regions of northern West Virginia. Although the demand for steam coal is not particularly keen, yet buying is on a somewhat larger scale than it has been recently.

Northwest

Dull Market May Precede Storm When Cold Comes

Bituminous Demand Is Just as Soft as Weather—Prices Weaken in Spots—Only Cry Is for Hard Coal—All-rail Competition Causes Concern.

Soft weather prevailing for more than a week is depressing the market and even though receipts from the Lakes are not tremendous, yet soft coal continues to pile up on the docks with consequent worry on the part of dock men and some shaving of prices here and there to move it. This is not true of hard coal, however. The demand in most quarters has grown stiffer as the days pass and prices, especially at Duluth, show an upward tendency. As much as $1 has been added on all sizes above buckwheat, which, as usual, is a drug. In Milwaukee the increase has not made any progress.

The volume of rail coal going into the Northwest is worrying many dock men. Illinois and Indiana mines are shipping steadily into southern sections of this territory, finding there a chance to expand a steam market that is almost dead in their own states. On the whole the situation is quite unsatisfactory for everybody concerned.

DULUTH

Anthracite is by far the most prominent feature here. With the advent of cold weather there was a general rush of hurry-up orders which has increased until by now dealers are at their wits end and are supplying lots of one and two tons. Two companies have advanced the price of anthracite $1 at the dock. Others may follow suit at once. Egg is selling at $13.50, nut at $13.80, stove at $13.75, pea at $12 and buckwheat remains $7.50 as before.

A firmer trend is noticed in bituminous prices, but there has been no upward change as yet, with the exception that the 25c. differential between Hocking and other soft coals has been eliminated.

Forty-four cargoes arrived during the week, of which seven were anthracite. On the way from lower ports are twenty-four of which four are hard coal. Vessel owners here have given assurance that there will be sufficient bottoms to carry all available supplies until freeze-up.

Official figures have not been released, but it is estimated that 1,600,000 tons were brought up during October. The majority of this was bituminous. According to C. P. White, federal administrator for the Northwest, this section will receive plenty of soft coal, but will only get about 30 per cent of needed anthracite by water.

Dock men here fear they are losing lower state customers to Illinois rail coal shippers.

MILWAUKEE

Mild weather has a soothing effect on the market. Demand is only fair, and there is an absence of concern as to the winter's fuel supply, notwithstanding disturbing newspaper reports predicting a big anthracite shortage. Reports of reduced prices in the Ohio and Pennsylvania tend to check buying of soft coal to some extent.

The yards are filling up with soft coal under heavy receipts by Lake. Coal will have to move to the interior much faster than it has if room is to be provided for the final rush before the close of navigation. Anthracite is coming slowly, and it is evident that dealers are wary about stocking up at present prices. There has been no change in prices of either coal or coke. Any raise in prices is bound to be scrutinized very closely by the state marketing commission.

October receipts by Lake, not including carferry receipts, aggregate 141,414 tons of anthracite, and 654,945 tons of soft coal, making the season's receipts 142,114 tons of the former, and 1,945,900 tons of the latter. Last year the receipts during the same period aggregated 855,750 tons of anthracite, and 2,319,716 tons of soft coal.

MINNEAPOLIS

The fall situation is a contest of endurance, with buyers holding out as long as they dare, and accordingly a great deal longer than good sense would dictate. The buyers have forced various concessions in prices on soft coals, both dock and all-rail even though the volume of fuel available or in prospect does not equal the required requirements.

If the prolonged endurance test works out to the advantage of the buyer again this year, it will be obvious that the wholesale trade will have a difficult task ahead to market coal in normal seasons—if there is ever to be such a period again. Buyers won in two or three endurance tests and feel their ability to overcome any situation that they may encounter.

There is left only about three weeks of navigation on the Great Lakes. And despite the excellent tonnages moved to the docks, the output for the season shows a sharp decline. Even after deducting the carry-over of last spring and figuring the tonnage consumed last year, the present season's totals are low. On any reasonable comparison of the two seasons the present winter will not have enough coal. And the surplus will have to be filled out with all-rail coal. Doubtless there will be a somewhat better showing from the Illinois mines than a year ago, but the tonnages will have to show a heavy gain to make this year's receipts equal to last year's consumption.

New England

Buying Falls off Again; Spot Prices Are Uncertain

Little Interest Evinced in Current Market—Wide Variation in Quotations and Only Scattered Tonnages Placed at Lowest Figure—Consumers Supplied in Advance.

Buying has again dropped off. There is so little interest in the current market that it is hard to say for just what prices spot coal is selling. Pocahontas and New River are being offered all the way from $8.50 down to $7.90 on cars, Boston or Providence, for inland delivery, but even at the lower figure only scattering tonnages are being placed.

The smaller consumers entered the market for moderate purchases ten days or so ago, but, having arranged for their requirements for the balance of the calendar year, they see no reason for buying still further in advance. The larger users have comfortable reserves, due chiefly to heavy receipts of British coal, and apparently there is no disposition even to sound the present market.

At the Virginia terminals a few cargoes are moved, but the great bulk of coal at the piers is being applied on early contracts. Most of the agencies have been out scouring the territory, but so far as reported their efforts bring only small results. In other words, the expected firmness in prices has not materialized.

The smokeless coals are being held at $6.75@7 per gross ton f.o.b. vessel. Accumulations, however, have accumulated more than 100,000 tons at the Hampton Roads ports, due not to increased demand at tidewater but partly because of smaller receipts from the mines and partly also on account of better car movement west. With the season advancing it is only natural, particularly in view of anthracite shortage, that the Western and Northwestern should absorb an increasing proportion of prepared coal.

The trade all over Central Pennsylvania continues quiet. Receipts at the Hudson River gateways show a fair average movement, but coal operators are apprehensive that orders will fall actually short of car supply. At the New York and Philadelphia piers there is practically no business of moment going

Cincinnati Gateway

Indecision Is Outstanding Feature of Spotty Market

No Notable Price Concessions with Lifting of C. & O. Embargo—Recessions Foreshadowed—Huge Movement of Loads, but Return of Empties Falls Behind.

The lifting of the embargo which the C. & O. enforced during the week ended Oct. 31 brought about another spotty market that has been more largely marked with indecision than price concessions. Evidences of coming drops in prices can be observed in rejections of coal shipped through the Cincinnati gateway to the steel interests in the neighborhood of Chicago as well as the industrial centers around Detroit and Toledo.

Car movement over the Ohio River bridges has again climbed to stupendous figures although the superintendent of terminals here pointedly remarks that there has not been a corresponding return of the empties. All three of the coal carriers using this as a connecting point are in distress through lack of motive power and shortage of cars. Most of the Hazard and Harlan mines report that are lucky to get 1½ to 2 days' supply of cars.

HIGH-VOLATILE FIELDS

Kanawha

An embargo imposed by the C. & O. on the eastward movement of Kanawha coal during the final week of October forced all the product of this field into Eastern markets where there was no demand whatsoever and to which producers of high-volatile coal had been making no effort to ship. The embargo thus had the effect of forcing further recessions in prices. Producers were forced to take $3 a ton or lower, with the alternative of closing down, as against a price of $4 in Western markets, with gas coal commanding a price of little less than $4.50. With the opening up restricted car supply made but little difference that usual.

Logan and Thacker

Embargoes also affected the Logan district. For operators had any Eastern orders when the embargoes became suddenly effective. Many of the mines were shut down during the last days of the month.

A great deal of interest was attached to the announcement made as to the abandonment of the strike called by the United Mine Workers in Mingo County in 1920. During the latter part of October and the first few days of November there was a somewhat better run of cars than in other fields as that Thacker mines were able to produce 40 per cent of normal. Prices prevailing in the West are fully $1 a ton higher than in the Eastern, and almost the entire product continues to move westward.

Northeastern Kentucky

Production in the section supplied by the C. & O. was upset during the closing week of October. The embargo bottled up most of the product since nearly all of it is being sold at the Lakes and in Inland West markets. Mine run, so far as Western delivery is concerned, is commanding a price of $3.75@$4.15 but the same coal in the East cannot be sold for more than $2.75 @$3.

LOW-VOLATILE FIELDS

New River and the Gulf

Embargoes diverting coal from normal channels and a shortage of cars disarranged conditions in the New River field during the last week of October. All C. & O. coal was being moved eastward, without regard to whether it was produced in high or low volatile territory. The additional coal shipped to Tidewater and Eastern territory in general only caused further price recessions. In the East smokeless mine run, particularly at Tidewater was little more than $3. Lump could have been sold at $6@$8.50 but most of the smokeless producers were not selling it above $6, owing to the agreement with government agencies.

Demand for Gulf fuel would have justified a production of more than 50 per cent, which was all that was possible owing to limited transportation facilities. Physical difficulties prevent the shipment of much tonnage to the West where much better prices prevail. It is not possible to obtain more than $3.50 for mine run at Tidewater whereas the same coal would bring $6 in Western markets.

Pocahontas and Tug River

Inasmuch as the N. & W. was the only road handling much smokeless for points west of the Ohio River, the Pocahontas region managed to get a little more coal into Western markets than other smokeless regions. The N. & W. is not encouraging a large Western movement owing to the difficulty in securing the return of empties. The average mine is working two days a week. Run of mine for Western delivery is bringing about $6 a ton as against $3.50@$4 at Tidewater. Lump is being limited to $6 per ton although producers could secure practically any price they desired if so disposed.

Tug River production is being gradually increased but mines are still experiencing a great deal of difficulty in securing all the cars they need. In the ordinary course of events most of the coal originating in this district is sent to the West, and hence only a certain class of equipment can be used. The demand for byproduct is fairly active. Mine run commands a price of $6 which is equal to that for egg and lump under the fair price agreement. Very little of the product is going east.

Cincinnati

Lake buying has again tapered off here which, with a foreshortening of the steel demand has cut the high prices a bit for byproduct and gas coals as well as the steam and splints. The former still maintain the premium that has been exacted for months past though there is not the big spread between the two prices that there was two or three weeks ago. Domestic buying has been a little lighter and the production greater which has inclined the values toward softness—nothing radical, but lacking in stability.

There has been virtually little change in the smokeless lines. The movement westward has been better because of the release of some of the smaller sized equipment that was held at the Lakes. This with the easing off of the Eastern markets has caused more attention to be paid to the Inland trade and it would surprise no one—with the close of fresh water carriage—to see a much heavier movement to the customers whose orders have been booked for months by both Pocahontas and New River concerns.

The retail situation shows no change. Figures are still under those promulgated by the Ohio Fuel Administrator with some splint lump selling as low as $8.75, delivered.

South

BIRMINGHAM

Each succeeding week seems to increase the gravity of the car situation, the shortage being reflected in a decrease of 10,000 tons in production for the week of Oct. 28, as compared with the previous period. Official figures show that only 45 per cent of the equipment ordered was furnished, and indications point to a less favorable showing for the current week, mines located on the L. & L. being very hard hit.

There has been no improvement in the steam coal market—in fact it is weaker, if anything, consumers showing little interest in acquiring a supply far in advance of requirements. The supply available for the spot trade is about in line with the volume of demand except as regards the lower grades, there being some surplus of Big Seam and the like. Quotations on better grades are holding up well.

Dealers in domestic coal are showing considerable concern in regard to winter supply. Numbers of yards are practically empty, while none has stocked to any extent as yet, and the slow movement and curtailed production is being viewed with alarm. A few days of sustained cool weather would wipe out the supply on local yards.

VIRGINIA

Production losses in one section are being offset by gains in other parts of the field with mines on the Southern producing a much larger percentage than usual. The total output is still adhering to about 65 per cent of normal. Production is hardly more than equal to the demand. The price at Tidewater is little more than $3 a ton. Falling prices have had a tendency to eliminate some of the smaller mines.

News Items From Field and Trade

ALABAMA

It is reported that hydraulic mining of coal will soon be inaugurated at Alco, near Shiras, by the **Alco Coal Co.** Arrangements have been made to transmit electricity from the transmission line of the Alabama Power Co. to the hydraulic plant, which will pump water from Hurricane Creek for washing away the surface of the coal. About 500 tons a day will be mined by the new method, according to an official of the company. This is the first time hydraulic mining as applied to coal has been tried. The Alco company has spent about $56,000 on its new plant.

Erskine Ramsey, vice-president and chief engineer of the Pratt Consolidated Coal Co., and well known capitalist, has donated $100,000 as a nucleus for the erection of an engineering hall at Auburn, Ala., in connection with the Alabama Polytechnic Institute. It is announced that the additional funds needed for the erection of the building will be in hand by the first of the year, the new building to be known as **The Ramsay Hall of Engineering.**

COLORADO

The office of the secretary of state has supplied the information that the **Alamo Coal Co.**, represented by **George C. Manley**, Denver, has been incorporated for $1,000,000. William B. Lewis, 40 Wall St., New York, and Harry F. Nash, Denver, are also mentioned as incorporators. Both are identified with the Oakdale Coal Co., Mr. Lewis as president and Mr. Nash as vice-president and general sales agent. The latter is also well-known as the secretary of the Colorado-New Mexico Coal Operator's Association. The mine of the new corporation will be opened near the Kebler properties of the Colorado Fuel & Iron Co. at Tioga, near Walsenburg.

Benedict Shubart of Lindrooth, Shubart & Co., Denver, made a business trip to Chicago and other eastern points late in October.

ILLINOIS

Much interest has again been caused in the regions around Franklin and Williamson counties by the rumor that the **Big Muddy River is to be dredged** so that coal barges can come up from the Mississipi and coal shipped by water to points all along the river. The movement this time is said to be backed by some large interests, among them being Edward F. Goltra of St. Louis, owner of a large barge line on the Mississippi. The dredging of the river would no doubt be a big assot to the coal fields of southern Illinois, inasmuch as it would to a certain extent relieve the car shortage and make it possible to ship coal to Chicago and destinations an equal distance south, at least $1 per ton cheaper.

Robert Clem, a resident of Herrin, has been named a member of the Illinois miners' examining board by Governor Small. The position involves attendance of the monthly examinations in Springfield and pays a salary of $1,800 a year.

Fred W. Price, mine manager at the mine of the Tamaron & Little Muddy Coal Co., Tamaron, was seriously burned in a gas explosion recently. He was hurriedly given medical aid and is expected to recover.

The Consolidated Coal Co., St. Louis with three mines in the Mt. Olive field one at Collinsville and one at Breese, has bought two steam shovel unloaders that will handle 1,000 tons of coal daily from cars. Tracks have been laid over a big acreage and screenings and nut from 3-in. down will be put in storage at central points to be taken up next spring and summer. This is caused by the poor market. It also indicates a belief on the part of some operators that there will be a good market for steam coal after April 1. The Consolidated will store several hundred thousand tons. The **Southern Coal, Coke & Mining Co.**, of St Louis, blazed the trail by doing this pioneer work last winter. Its huge piles of storage coal were drawn on from April 1 to Aug. 1 and were to some extent the means of keeping the market from soaring on western Kentucky coals.

The Rex Coal Mining Co., of Rock Island, has been incorporated with capital of $20,000 and work has been begun on a mine one-half mile east of Warner. H. E. Bishop is president of the new company; C. L. Hintz, vice-president; and C. W Krueger, secretary and treasurer These men all live in Rock Island, and with A. Hintz and H. V. Burt, compose the board of directors. The lease obtained by the company consists of 600 acres.

It is stated that the **Kincaid Railway & Mine Supply Foundry**, of Kincaid, has been sold by the Peabody interests to **Duncan Brothers**, of Alton. It is also stated that the Kincaid plant will be operated in connection with the Alton plant, the latter employing over 500 men. The Kincaid factory has been closed since March 30.

The Great Lakes Coal & Coke Co., Chicago, with a capital stock of $125,000, has filed incorporation papers. The company will mine and deal in coal coke, by-products, etc. The incorporators are: Rushton L. Fordyce, George Shakel, and Walter Gramm.

The Buckley Coal Corporation has been incorporated at Springfield. The company is capitalized at $100,000. The concern will acquire mines and mine coal and other minerals. The incorporators are George W. Shwaner, Carl H. Eschoff, and Edgar H. Buckley.

J. D. Tracy, of the Department of the Interior, Bureau of Mines, who has been located at the Pittsburgh, Pa., experimental station, has been transferred to the Urbana station of the United States Bureau of Mines.

F. T. Lovering, for many years Western foundry representative of Pickands-Brown & Co., Chicago, has resigned, joining the force of Atwill-Makemson Coke & Coal Co., Chicago. Mr. Lovering will have entire charge of Western sales of foundry coke. **Atwill-Makemson Coke & Coal Co.** have recently been appointed exclusive sales representatives for the sale of Sloss-Sheffield Steel & Iron Co.'s solvay foundry coke, formerly handled by David Evans & Co., Chicago.

INDIANA

The Evansville Coal Co., of Evansville, has filed articles of incorporation and will engage both in wholesale and retail coal sales. The directors of the company are Charles W. and Frederick Cook of Evansville, Thomas C. Mullins, mayor of Boonville, and Samuel Ashby, an attorney of Indianapolis.

The Ramabo Coal Co., Indianapolis, has been incorporated with capital of $25,000. Directors, Charles S. Raub, Simon J. Martenet, Ferdinand Born.

IOWA

Fred Harper, and associates, of Givin, have organized the **Given Coal Co.** and are sinking a slope mine on the C. H. Colvin farm, two miles northeast of Givin. The mine will be open Jan. 1.

The Charles Schuler Coal Co., of Davenport, Iowa, is ready to operate a new mine two miles east of Alpha, Ill., on the Burlington an extensive switching system having been laid out within the past month. The mine is located about two miles from the railroad. The new mine is preparing to operate on a daily capacity of 35 cars. Mining rights on more than 2,000 acres have been secured.

KENTUCKY

Recent state incorporations include the **Moss Federal Coal Co.**, Pineville, capital $ 0,000, M. J. Moss, M. J. Moss, Jr., and M. H. Moss, incorporators; **English Ridge Coal Mining Co.**, Ryan, $5,000, J. J. Gregory, J. C. Fawbush and W. H. Rankin; **Ed White Coal Co.**, Dublin, $5,000, Edward White, John Stamper, Jr. and A. M. Hassell.

It is reported from Letcher County that J. L. McCormick of the firm of McCormick Va., representing the **Mineral Development Co.**, a Philadelphia coal holding corporation owning considerable undeveloped coal acreage in eastern Kentucky, is now in Letcher County securing leases, with plans for large development of coal properties in the Elkhorn fields, but without much possibility of development work until next year.

According to a press dispatch, official notice has been made of the **resignation of S. A. Keller**, of Middlesboro, as president of district 19 U. M. W., embracing the southeastern Kentucky and eastern Tennessee district. It is reported that the resignation along with that of **J. W. Brooks**, vice-president, was accepted by National President Lewis. **William Turnblazer**, national organizer, has been appointed district president, according to the report. The resignations and appointment became effective Nov. 1.

MARYLAND

For the time being it has been decided by the **Georges Creek Coal Co.** to abandon any attempt to operate the Big Vein mines of the company at Lonaconing, Md., and the company has resigned its organization and boarded up its mines. The company attempted to operate by a small force but the few men at work having received threatening letters, failed to report and the company has thought it advisable to suspend operations until more favorable conditions obtain. This concern will continue to operate its mines in West Virginia and western Pennsylvania.

MICHIGAN

Michigan's recently enacted fuel control law has not so far increased the available supply of coal nor is there given the legislation for any reduction in cost of fuel for domestic or steam use. Applications are being filed by brokers and other representatives of the coal trade who are required to take out state licenses. The applications embody information concerning the amount of coal or coke sold by the applicant last season, the amount sold so far this year and the quantity in possession of the dealer at the date of making a license.

MINNESOTA

The retail trade of the Northwest has been **urged to authorize shipping coal from the docks to the interior in open top cars** as a means of relieving the car shortage. Box cars are preferred, however, for winter shipping.

C. P. White, fuel statistician for the Northwest is urging consumers in that territory to lay in their fuel now and so aid in distributing coal as economically as possible.

The use of peat is urged upon farmers of Minnesota, who may have deposits available. Peat exists in considerable of the counties of the state. It is reported to be the equal in heating value of Australian wood. At a test made recently at Duluth, however, peat at a cost for fuel was found to be a failure. Although cheaper in the pure than coal it was found that a much larger force of men was required to handle the peat and that the bulk made storage and moving problems burdensome.

MISSOURI

The Kansas City Light & Power Co., which owns [illegible] of coal land located at Prairie Hill, has a force of surveyors at work selecting the route for a railroad from Salisbury to the coal lands. It is expected that the survey will be completed in about two months. A survey also will be made from the coal lands to Cairo in Macon County and the company is actively engaged in securing the [illegible] affording a connection with the Burlington road as well as the Wabash. The output from the coal lands is being contracted at this time. As soon as the road is completed it is planned the company will operate its own mines. The company is also interested in the development of the coal land and will mine the coal for its own plants, the remainder of the coal and other deposits.

Development of the coal field along the western border of Bates County has resulted in the boarding of [illegible] a mile from the Missouri-Kansas line, on the Wathena, and is already in reality an industrial town. Four companies of coal operators have [illegible] along the main line. Several more buildings are under construction.

E. L. Barton is opening up a coal mine west of Boonville. It will be the largest in that county.

Keystone Coal & Mining Co. of Baltimore

Mine Builders

St. Louis Coal Co., of St. Louis, capital

Carter Coal Co., of Lexington, capital

Carter-Mayo Coal & Grain Co.

The West Missouri Power Co. has bought

NEW MEXICO

The St. Louis Rocky Mountain & Pacific Co. at Raton, has awarded to Stearns-Roger Mfg. Co., Denver, a contract for furnishing the machinery for the new steel tipple at the Van Houten Mines. The power of the plant will be under the direction of **Frank A. Young**, chief engineer of mines, is now perfecting a central washing and preparation.

NEW YORK

The National Exposition of Power and Mechanical Engineering will open in the Grand Central Palace, New York City, and will remain open until Dec. 14, except on the intervening Sunday. The exposition will be the first large scale attempt to display mechanical and power plant apparatus so that the general consumer's state of development will be apparent and only to the highly trained engineer may he be the layman with knowledge of the newer developments. There will be seven sessions of the various devices that enter into the process of taking coal from the mine, handling it at the power plant, burning it to make steam to generate electric power and sending the current out through wires to the consumer.

The Mather Collieries Co., of Cleveland, a holding company for the Nos. 6 and 8 mines, has changed its business office to the Marion Trust Bldg.

Charles V. Crandall, vice-president of the Tennessee Coal Corporation of Knoxville, Tenn., is now making a tour of coal & iron properties, for investment purposes, and incidentally for the improvement of **C. B. Goode** of New York, a native of Amsterdam, Holland.

Lee Lattimore, son of Dr. and Mrs. Lattimore of the Quemahoning Coal field, with headquarters at Cumberland, Md., was a recent visitor to the New York market.

OHIO

Alex Vessels, who is identified with the Cleveland office of the Walter L. Ross Coal Co., has been promoted to a post of assistant to the general manager of the Ross Quemahoning Coal Co., also of Cleveland, of which he is interested.

Robert S. Tyson, treasurer of the Ohio Mahoning Coal Co. of Youngstown, was a recent guest of the officials of the Ohio Quemahoning Coal Co. at Cleveland.

Frank Easley, president of the Jamison Coal & Coke Co., and **Pat Casey**, of the Pat Casey Co., Akron, were visitors at the Cleveland Coal Exchange the week of Oct. 9.

I. E. Woods, of the Crystal Block Coal Co., Cleveland, is confined to his home with a broken leg.

Products against coal and oil companies have been started in the Hamilton County Common Pleas Court by the Hamilton Coal Co., Cincinnati. Unsecured claims are asked for $1,000 and $2,000 respectively. The petitioners allege that the defendants have failed to pay for coal delivered to them.

Frederick Gilbert, of Cleveland, has been appointed receiver for the Ohio Fuel Co., Columbus, by Judge Wilkin of the Federal Court. The receivership is the result of a suit brought by the Ohio Fuel Co. to collect $1,000 alleged to be due for coal delivered to the defendant company. The receivership is not expected to interfere with the operation of the company's mines.

Mine Workers operating mines south of Jackson are preparing to ask a wage increase of 10c. per ton, it is reported. The mines are located in the Madison district.

OKLAHOMA

Drills have been busy for many months prospecting up the coal lands lying northwest of Vinita, southeast of Centralia and west of Welch and Bluejacket, and veins have been found underneath a vast area. One transaction alone shows the **magnitude of the expected development.** It is the filing in a Chicago trust company of a mortgage for $4,500,000 given by the **Central Coal & Coke Co.** on 70,000 acres of coal rights. To tap this coal country a railroad has been proposed extending the Miami electric line going west through the coal fields to Tahlequah, and this line is only awaiting some money to build. Another road has been proposed from Caney to Vinita. Still other lines have been proposed from the Missouri Pacific, in Kansas, into the coal fields.

The Pittsburgh-Midway Coal Co., which has been operating one steam shovel near Chisholm, has installed a second shovel. It is taking the coal out at a depth of about 14 ft. This company has bought outright several hundred acres of land and is pushing operations in an aggressive way.

PENNSYLVANIA

R. E. Garrett, J. E. Stewart, D. E. Thompson, T. F. Miller and Charles Buchman, constituting the mines committee of the **Bertha Coal Co.**, Pittsburgh, have just returned from an extensive survey of the company's properties in Pennsylvania, Ohio, West Virginia and Kentucky. Despite many production handicaps the company will show an output of 500,000 tons greater than any previous year. This company is now building plans whereby production will be greatly increased in 1923.

One of the side issues of the seven-month industrial struggle in the **non-union fields of the Berwind-White Co.**, was pointed in the miners last week at the hearing conducted by **Mayor Hylan's investigating committee** from New York City. It looks to the Ohio as though it was simply a well-organized plan by union officials to get some publicity and possibly sympathy and help from outside sources. Mining conditions are good at Windber and the Berwind-White Co. is paying as much, and in some instances more, than the union operators. It is understood the company has offered work to all who want it.

More coal lands were sold at sheriff's sale in Greene County, Pa., on Oct. 9 than in any previous sale in the history of the county. The sale was attended by a large crowd of buyers and bidding was spirited. The principal tract sold was that of the Pittsburgh Coal Co., which was purchased by the Pittsburgh Coal Co. of Delaware, a subsidiary company. There was no intimation as to what the deal would be closed.

James P. Walsh, vice-president of the Pittsburgh Coal Co., in charge of sales, has resigned.

The partnership conducting business under the name of the **Phoenix Coal & Coke Co.** has been dissolved. **H. C. Schade** will continue business under the old name.

At the annual meeting of the **Pennsylvania State Chamber of Commerce**, which convenes in Harrisburg on Nov. 14, **W. D. B. Aiken**, chairman of the public service commission, will discuss the coal situation. Mr. Aiken is prepared to talk on all phases of the question and to discuss findings of the commission as to supply, price and distribution, disclosing facts and basic conditions of interest to both producer and consumer. The program contains an exceptional number of speakers, which include Governor William C. Sproul, Former Governor Frank O. Lowden of Illinois, United States Senator David A. Reed, Dr. J. T. Holdsworth of Pittsburgh and Vernon F. Taylor of Indiana.

Shipments of anthracite for the coal year, April 1 to Sept. 30, 1922, as compared with the corresponding period last year, and reported to the Anthracite Bureau of Information by the initial transportation lines, were as follows:

	Coal Year to end of Sept., 1922 Tons	Coal Year to end of Sept., 1921 Tons
P. & R. Ry.	926,516	6,628,806
L. V. R.R.	950,769	6,037,810
C. R.R. of N. J.	345,447	3,282,575
D. L. & W. R.R.	560,717	5,470,016
D. & H. Co.	533,858	4,489,212
Penn. R.R.	382,007	2,439,508
Erie R.R.	497,841	3,696,454
N. Y. O. & W. Ry.	128,427	778,937
L. & N. E. R.R.	181,550	1,529,266
Total	4,507,132	34,350,584

Coal mining companies in Cambria County have filed appeals with the county commissioners from the triennial assessment on the grounds that the real estate was not assessed at the actual value thereof, being assessed without due regard to the valuation and assessment made of other similar properties in the country, but was assessed in excess of the value and assessment of such other properties. The following companies filed appeals: Holding of the **Wilmore Coal Co.**, Richland and Adams townships and Scalp Level borough and Conemaugh, Croyle and Stonycreek townships; **Berwind-White Coal Co.**, Richland and Adams townships and Scalp Level borough; **Maryland Coal Co.**, Richland, Croyle and Adams townships.

Wellington M. Bertolet, of Reading, has been appointed as state director of anthracite and has reported to the State Fuel Commission to act in conjunction with **R. C. Morse, Jr.**, director of transportation, and **E. W. Parker**, director of anthracite distribution. The appointment had been made in order to apportion equitably the allotment of anthracite among Pennsylvania consumers and to secure a fair adjustment of coal shipments to local dealers and thereby secure greater public relief in the present emergency.

TEXAS

LEE M. POOL
President Retail Coal Dealers' Association of Texas

Lee M. Pool, of Greenville, is the new president of the Retail Coal Dealers' Association of Texas. Mr. Pool is a young and progressive retail coal dealer at Greenville, and is taking an active interest in association affairs.

VIRGINIA

The Virginian Railway is ready to proceed with **construction of its new steel coal pier** adjoining its present pier at Sewall's point. The new structure will cost slightly over $3,000,000 and will require two years to build. Sanford & Brooks, of Norfolk and Baltimore, will do the piling and build the super-structure, while the Bethlehem Steel Bridge Corporation will build the pier. The Atlantic, Gulf & Pacific Co., of Norfolk, will do the dredging. Plans for the pier are to make it the most modern in the world.

Depression in the coal business was assigned as the reason for the closing Nov. 1 of the Norfolk offices of the **Willard Sutherland Corporation. Chester B. Koontz**, formerly with the West Virginia Coal Co., handled the business for the corporation.

WEST VIRGINIA

It has been possible to increase production to 5,000 tons per month at the plant of **Gilbert Smith** on Lick Fork in the New River field. Development work was not begun at this plant until late in June so that the owners of the mine believe that favorable progress has been made in getting the property on a productive basis.

The Consolidation Coal Co. has taken steps to build an industrial town of 2,500 homes at Coalwood, believed the largest enterprise of the kind ever undertaken. It will involve an expenditure of over $10,000,000.

The following West Virginia coal corporations have increased their capital stock in the amount named or else have been granted authority to do so by the state secretary: **Virginia Fuel Co.**, from $20,000 to $100,000; **Home Coal Co.**, from $25,000 to $100,000; **Raleigh Wyoming Coal Co.**, from $500,000 to $3,500,000; **Columbia Coal Co.**, from $90,000 to $165,000. **The New Republic Coal Co.** has been granted authority to decrease its capital stock from $250,000 to $50,000.

The plant of the **Standard Thacker Coal Co.**, operating on the Polk Harris farm west of Williamson has changed hands, having been bought by a company in which Judge R. D. Bailey of the circuit court, Sheriff A. C. Pinson of Mingo County and Andy New are prominent stockholders. The purchase price is understood to have been approximately $70,000.

The Price Hill Collieries Co., operating near Mt. Hope, is adding new equipment to its plant and has placed a contract with the Fairmont Mining Machinery Co., for a three-track shaker screening outfit, equipped with loading booms.

In line with other improvements being made at the plant of the **Cambria Coal Co.**, of Clarksburg, the object of which is to increase the productive capacity of the mine, a bar screen outfit is being added to the equipment at the company's plant.

Charleston capitalists have launched the **Gilbro Coal Co.**, the offices of which are to be at Charleston. This concern has a capital stock of $50,000. Active in organizing the company were W. M. Gillie, Duke W. Hill, P. S. Stewart, S. H. Harrison and T. Brooke Price, all of Charleston.

Organization of the **William Ann Coal Co.** of Huntington presages operations on a large scale, this company being capitalized at $200,000. Interested in the new concern are: Joseph H. Bowen, and E. S. Baker of Bramwell; D. T. Prichard and W. E. Prichard of Huntington; D. H. Prichard of Cincinnati.

Owing to the fact that they did not like one of the teamsters employed at one of the plants of the **Gilbert and Davis interests on Scott's Run** in Monongalia County, **approximately 300 miners went on strike** on Oct. 26, and for a time refused to work, notwithstanding the fact that officials of the union informed them they were violating the terms of the contract made with the operators. Matters even went so far that the president of sub-district No. 4 conferred with International President John L. Lewis with a view to having the charter of local No. 4775 on Scott's Run revoked. Later, officials in the union went to Scott's Run to talk to the men and to induce them to return to work without further violation of the union contract.

For his participation in the attacks on Willis Branch during a period of two years and particularly for his part in the conspiracy to remove a machine gun from the station of the Virginian Ry., at Pax, **George Barrett**, an international organizer of the United Mine Workers for district No. 29 was sentenced in the circuit court of Pocahontas County, during the last week of October, to **serve six years in the West Virginia State Penitentiary.** Some of those implicated in the plot turned state's evidence and it was largely on their testimony that the jury found a verdict of guilty. "Flat" Williams, one of the witnesses for the state, testified as to his part in the plot but stated that he thought the machine gun might have belonged to Barrett since he had been told that guns were being shipped in to aid the union cause.

W. E. Deegans, who is widely interested in southern West Virginia coal properties is one of the leading figures in the newly organized **Beda Smokeless Coal Co.**, which will have its principal office at Huntington. This company has an authorized capital stock of $25,000. Others interested in the new corporation are: Kathryn Deegans, Huntington; John B. Hofmier, Fort Worth, Tex.; J. P. Chapman and M. A. Chapman, of East Bank.

CANADA

"The coal measures of Vancouver Island" is the subject of a report prepared by **Dr. J. D. Mackenzie**, head of the B. C. Office, of the Canadian Geological Survey, who has been engaged in the indicated researches for the past two years. He is of the opinion that the amount of recoverable coal on the island is considerably below what has been estimated. He points out that there are three workable coal horizons in the Nanaimo district, and only one in the Comox district, the latter lying over the pre-cretaceous or barren formation and disturbed by protrusions of the latter in places.

Finding the **sale of Welsh coal to be drugging**, the Brantford, Ont., City Council has reduced the price to $18 per ton. Niagara Falls, Ont., coal dealers have complained that in their purchases of coal supplies they are compelled to pay a freight charge of 70c. per ton for haulage across the Suspension Bridge, a matter of a few hundred feet. Fuel consumers on the Canadian side, however, can order from Niagara Falls, N. Y., dealers, and have it transported across the bridge in wagons for something like 15c. per ton. The Ontario Fuel Commissioner has advised that he has no jurisdiction in the matter.

Dr. W. H. Collins, Director of the Geological Survey, Dominion Department of Mines, on his return from a three weeks' visit to the various field parties who are at work surveying the **mineral industry of Nova Scotia and New Brunswick**, reports new coal beds, the existence of which was unsuspected, and deposits of oil shale in both provinces. They are not yet being mined, but constitute the basis of an important future mining industry, he says.

William A. Sherman, president of district 18 of the United Mine Workers, has announced that at the close of the present agreement between the operators and the union the latter would demand a **continuation of the present wage scale, but with a six-hour day and a five-day week**, instead of an eight-hour day and a six-day week. The present agreement terminates on March 31, 1923. The district includes eastern British Columbia and southern Alberta.

A special committee has been appointed by the Dominion Government to **investigate the possibility of adapting Canadian coal to furnace use** as a means of relieving the fuel situation. The members are **Dr. Charles Camsell**, Deputy Minister of Mines, chairman; **F. C. C. Lynch**, chief of the Natural Resources branch of the Interior Department, secretary; **J. D. McLeish, E. P. Hamel and D. B. Dowling** of the Mines Department, and **J. H. Challies**, chairman of the Dominion Water Power Board. A proposal to relieve the situation is the importation of the best grades of Welsh anthracite during the summer months. Dr. Camsell believed that Welsh anthracite of the finest quality free of dust would be available for transportation to Canada commencing in April of each year. This coal has an ash content of approximately 1 per cent as compared with the ash content of American anthracite, which sometimes runs as high as 15 per cent according to the analysis of government experts. It was understood that the summer importation of Welsh coal would involve stockpiling the anthracite as it comes from the mines and doing the screening and sizing in Montreal. Dr. Camsell intimated that the people of Quebec and Ontario need not look for relief immediately as it could only come after careful study and preparation.

A statement issued by the Dominion Bureau of Statistics states that the **output from Canadian mines during July** amounted to [illegible] tons, an increase of [illegible] tons over the preceding month but short of the average record for July by the three preceding years by [illegible] tons or 18 per cent. The output for the first seven months of the year was less by 1,[illegible] tons than the average for the same months of the last three years. **Imports in July** were 447,000 tons, a decline of 13 per cent below the record for June. Imports during the first seven months of the year were 41 per cent below the 3-year average for the same period. **Exports in July** were [illegible] tons, as compared with 9[illegible] tons in June. The record for the calendar year on the other hand was 19 per cent below the average for the seven months period of the last 3 years. The net result of the movements of coal during July was that the amount made available for consumption in Canada was 1,[illegible],000 tons as compared with a 3-year average for July of 2,[illegible] tons. For the first seven months of the year the amount made available for consumption was 11,[illegible],000 tons, as compared with a 3-year average for the same period of 16,230,[illegible] tons.

WASHINGTON, D. C.

Bids are requested by the Navy Department for the supply of [illegible] 1923 at various points in New York, Massachusetts, New Jersey, Pennsylvania, Virginia, Maryland and the District of Columbia, under Schedule [illegible], Requisition [illegible] N S A, Bureau [illegible] and [illegible] will be opened Nov. 24, 1922.

The United States Civil Service Commission announces an open **competitive examination for laboratorian** on Dec. 6 and 7, 1922. Vacancies in the federal chemical service throughout the United States, including the Departmental Service, Washington, D. C., at $1,[illegible] to $1,[illegible] a year, or higher or lower salaries, will be filled from this examination, unless it is found to the interest of the service to fill any vacancy by reinstatement, transfer, or promotion. Applicants should at once apply for Form 1312, stating the title of the examination desired.

Not later than Dec. 1 officials of the **American Mining Congress** expect to have the industrial co-operation plan which was outlined at the Cleveland convention functioning in its preliminary phases. The method of procedure contemplates a thorough study of conditions in all mining fields by sectional committees which will pay particular attention to the adequacy systems of welfare work and other forms of co-operation between employers and employees already in operation. These sectional committees probably will be named, each working under the direction of a chairman and reporting to a general chairman. In those regions where more than one class of mining is in operation, it is probable that subcommittees will be named from the sectional committees to undertake a study of the work and needs of a specific type of mining.

The United States Supreme Court has upheld the arguments on the **constitutionality of the Kohler mine cave law** [illegible]. Ordinarily the case would not have been reached for a year at least. The request for the advancement of the case was made recently by attorneys W. D. Van [illegible] J. Mahon. The action was started by the latter against the Pennsylvania Coal Co. and in the Supreme Court of Pennsylvania the law was declared valid.

The resignation of Dr. George Otis Smith, as director of the Geological Survey, [illegible] to engage in [illegible] The Federal Coal Trade Commission, was announced recently at the White House with the statement that it was hoped he would be able to remain [illegible] after which the commission expects to [illegible] report.

The work of mine rescue car No. 4 of the **United States Bureau of Mines** [illegible] conducted classes in rescue and first-aid training at Wyoming, Pa., and Millport, Pa. This car was closed to the general [illegible] at the Warren County Fair, Pa., [illegible] First-aid classes have been conducted by the personnel of car No. 4 at Saginaw and Bay City, Mich. Car No. 7 recently conducted **first-aid training** at Alma and Ionia, Mich. At the West Virginia State Fair at Wheeling demonstrations of the use of oxygen breathing apparatus by a mine rescue team [illegible] were given by the crew of car No. 4, which was manned by representatives of the Bureau of Mines and the Pittsburgh Coal Co. Later, at the West Virginia Fair at Charleston, similar exhibitions were given by [illegible] probably 15,000 persons. It is estimated that 4,000 persons a day, [illegible] of whom were women, visited the mine rescue station during the [illegible] Mines at the coal and [illegible] at Huntington, W. Va., car No. 4 co-operated with the West Virginia Department of Mines in exhibits at the [illegible] County Fair at Ulysses, where [illegible] visited the car.

Traffic News

The Cincinnati, Indianapolis & Western R.R. is now transporting about 1,000 tons of coal a day, a portion of which is used on the company's road, the remainder being sold to other railroads and to manufacturing plants. This company purchased some 20 miles of the abandoned C. & O. R.R. line, known as the Chesapeake & Ohio Coal R.R., the transportation facilities of which are being used for the first shipment of coal from the company's property.

The L. & N. is giving cheer to the coal industry with its announcements of new power and cars and other equipment purchased and its plans for development of its coal properties in Kentucky. The expenditures of about $12,000,000 has been authorized during the last year of which half will go into channels of direct benefit to coal shippers.

The I. C. C. has granted reparation to several Carterville, Ill., operators who had complained against rates from mines in Kentucky. Rates were unreasonable from June 25, 1918, to March 1, 1920.

The Clarksville Ice & Coal Co., Red River Ice Works and several others were parties to the complaint.

Reparation has been awarded the **Indiana Block & Tiller Co.** to cover unreasonable rates charged for the movement of coal from certain mines in Indiana to Vincennes and Terre Haute. The I. C. C. finds that the rates were unreasonable to the extent that they exceeded 45c. for hauls of ten miles and under, 60c. for hauls of ten and not over thirty miles, and 75c. for hauls of over thirty miles.

The rate charged between Missabe Junction, to Steelton Mine, was cancelled unreasonable by the **Minnesota Steel Co.** of Duluth. The Interstate Commerce Commission found that the rates charged were unjust or unreasonable.

The complaining firm held that the rates on coal from the anthracite region to certain points in northern New York are unreasonable or otherwise unlawful.

The rates charged on coal from mines in the central and southern districts to Edgewood and Burton Grove, Ia. are held to be unreasonable in a report prepared for the commission by Examiner Disque.

The case of the **Pittsburgh Coal Producers Association versus the P. C. C. & St. L. R. R.** was considered at a hearing assigned from 70 to Examiner by Commissioner Eastman.

An order limiting to **car supply to wagon mines,** similar to that made by the I. C. C. has been issued by the **Public Service Commission of Pennsylvania.** Upon any day that such commission learns that the mines with two-compartment system of mine-run coal shall not be furnished or supplied by any railroad which customarily does not load or is unable to load such coal in both compartments, then the mines of whatsoever kind or system from which such coal has been customarily loaded with such cars.

Purchase of 1,500 coal cars is a part of the program of the **Virginian Railway** for the handling of additional coal from the Winding Gulf and other territory in southern West Virginia, according to an announcement just made by Vice-President Ely of that road. Additional locomotives will also be required, it is said, but the company has not completed plans for the purchase of these. It will not build any additional repair shops although the company has recognized that it will not have any unnecessary cars for handling equipment.

Trade Literature

Power Hoe (Improved Drag Scraper). Link Belt Co., Chicago, Ill. Book No. 444. Pp. 31, 6 x 9 in.; illustrated. Describes how the power hoe takes coal to storage from pile alongside railroad track and also how it is reclaimed from storage by this device.—Advertiser.

Sullivan "WH-3" Air Compressors. Sullivan Machinery Co., Chicago, Ill. Bulletin 75-12. Pp. 12, 6 x 9 in.; illustrated. Among the advantages claimed for these machines is economy of steam, that the efficiency of its air end is higher, that its working parts are more accessible and that it is less expensive.—Advertiser.

Sullivan Power-Driven Air Compressors. Sullivan Machinery Co., Chicago, Ill. Bulletin 77-12. Pp. 16; 6 x 9 in.; illustrated. Describes the power-driven wafer valve air compressors, class WG-6, single stage; class WH-6, two-stage belted; and class WK-6, direct motor driven.—Advertiser.

Relays. General Electric Co., Schenectady, N. Y. Bulletin No. 47,606. Pp. 25; 8 x 10 in.; illustrated. Covers the operation and general application of relays, with particular consideration to the selection of relays for the protection of systems against troubles due to line faults.—Advertiser.

The Value of Accurate Testing of Coal. Pittsburgh Testing Laboratory, Pittsburgh, Pa. Bulletin 24. This is a four-page pamphlet, 8 x 11 in., with a page of illustrations showing the proper method of preparing a sample of coal by hand.

Cochrane Combined Catalog. H. S. B. W.-Cochrane Corp., Philadelphia. Publication No. 1080; pp. 210; 6 x 9 in.; illustrated. Describes this concern's varied line of open feed-water heaters, V-notch meters, metering heaters, flow meters for fluids in pipes, water softeners (including both hot and cold processes) pressure filters, back-pressure valves (including valves for atmospheric relief service and flow valves) steam and oil separators drainers or traps. Among the new devices shown is a deaerating heater and a flow meter for measuring the flow in pipes.

Pneumatic Collecting and Conveying Systems. B. F. Sturtevant Co., Hyde Park, Boston, Mass. Catalog No 291. Pp. 72; 8 x 11 in., illustrated. Covers the application of Sturtevant fans to air-washing systems, removal of dust from coal breakers and grinding, buffing and polishing wheels, the conveying of pulverized coal and the removal of fumes and gases. It also contains 17 pages of tables on how to find the size of fans, the suction, volume, r.p.m. and horsepower for any system, cubic feet of air handled per minute, size of pipe and sheet steel, etc.

Line-Shafting Equipment. The Medart Co., St. Louis, Mo. Catalog No 43. Pp. 182, 7 x 7 in., illustrated; tables.—Advertiser.

Federal Fuel Control Notes

A conference of Fuel Administrator Spens and his special counsel, C. J. Hepburn, and Ohio Federal Representative Commander H. B. Bouton, with Governor Harry L. Davis, Ohio Fuel Administrator C. J. Neal and Attorney General John C. Price was held at Columbus Nov. 1 for the purpose of securing coal supplies for the people of Ohio, in view of the fact that a large part of Ohio-produced prepared sizes are going outside of the state where higher prices are obtainable. For some time Ohio Administrator Neal has been asking Mr. Spens to relieve the Ohio situation, which is becoming acute. The conference was the result of the threat of Ohio Administrator Neal that unless some relief was forthcoming he would seize Ohio mines as is provided in the emergency measure enacted at special session of the Ohio legislature. A number of Ohio operators joined in the conference and when the question of shipping Ohio product within the state was put up to them there was a general willingness to co-operate. Administrator Spens attended the matter of preventing cross hauling as it were, and thus relieve the railroad situation. The conference adjourned without any definite action taken. It was announced that there would be no increase in the Ohio fair price list at this time as these prices were believed to be fair and reasonable.

The first instance of submission of a coal price dispute case by the Pennsylvania Fuel Commission to the federal fuel authorities occurred Oct. 28, when W. D. Ft. Amey, chairman of the Pennsylvania commission turned over to Fuel Director Spens the case of the **Mill Creek Coal Co.**, selling through the **Delano Coal Co.**, of Philadelphia. Chairman Amey made the following statement of the case: "The prices for anthracite charged by the Mill Creek company, selling through the Delano company, being largely in excess of prices fixed in Governor Sproul's proclamation, have been complained against by the fuel administrators of several states. These companies have been requested, and opportunity offered them to appear before the Fair Practices Committee to exhibit their cost figures and to justify their prices. By report of that committee these companies have neglected or refused to present themselves before that body. The recommendation of the Fair Practices Committee is that they be certified to the Federal Fuel Administrator at Washington, for such action as he thinks expedient, and in this the Pennsylvania Fuel Commission concurs. I have accordingly today submitted the Fair Practices Committee's report to Fuel Director Spens."

Obituary

William S. Porteous, age 85 years, died at Amherst, N. S., Oct. 23. He was born in New York and came to Nova Scotia 30 years ago and had been in the coal business in Amherst for the last 21 years.

Byran G. Tighe, pioneer in the coal industry in Chicago, died recently. He was vice-president of the Bickett Coal & Coke Co.

Melvin E. Lynn, sales manager for the Campbell's Creek Coal Co. at Cincinnati died suddenly at his home on Oct. 29. He was a native of McKeesport, Pa., and the son of a coal operator of western Pennsylvania. He joined the forces of the company nearly forty years ago. Mr. Lynn was an ardent supporter of the idea of coal transportation by water and was a member of the Ohio Valley Improvement Association.

John Hergoyne Foote, president and treasurer of Foote Bros. Gear & Machine Co., Chicago, died recently. He was known all over the country not only for his skill as a gear maker and inventor for transmission and other machinery but for his keen interest in anything that would further efficiency in machine operation.

Coming Meetings

The Illinois Mining Institute will hold its next meeting Dec. 1 and 2 at Urbana, Ill. Secretary, Martin Bolt, Springfield, Ill.

Pittsburgh Wholesale Coal Association will hold its annual meeting Nov. 14, at Pittsburgh, Pa. Secretary, W. R. Crowthers, Pittsburgh.

West Virginia Coal Mining Institute's annual meeting will be held Dec. 5 and 6, at Huntington, W. Va. Secretary, R. E. Sherwood, Kanawha Bank Bldg., Charleston, W. Va.

Harlan County Coal Operator's Association will meet Nov. 15, at Harlan, Ky. Secretary, E. R. Clayton, Harlan, Ky.

The National Industrial Traffic League will hold its annual meeting Nov. 15 and 16 at the Hotel Commodore, New York City. Secretary, J. H. Beek, Chicago, Ill.

Coal Mining Institute of America will meet Dec. 13, 14 and 15 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., 911 Chamber of Commerce Bldg., Pittsburgh, Pa.

National Exposition of Power and Mechanical Engineering will be held at the Grand Central Palace, New York City, Dec. 7-13. Manager, Charles F. Roth, Grand Central Palace, New York City.

Canadian Institute of Mining and Metallurgy, annual Western meeting Nov. 15-17, at Vancouver, B. C. Secretary-Treasurer, G. C. Mackenzie, Montreal, Quebec, Can.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 22 NEW YORK, THURSDAY, NOVEMBER 16, 1922 Number 20

Portent of the Report on Coal Stocks

COAL producers needs must look deep into the stock report of the Geological Survey last week to find comfort. The consumers are told by their Washington organization, the United States Chamber of Commerce, to consider the soft-coal crisis over and to go into the market for winter supplies. The Chamber says the trouble is over. It is understood that the Interstate Commerce Commission is actively considering the lifting of the service order that gives coal preference and priority in transportation and in the use of cars. For weeks the production of soft coal has been increasing and the price declining. Stocks are now at a point above 35,000,000 tons, sufficient for thirty days on the average.

There are several things that will prevent the coal market from sinking to the deadly monotony of two years ago. One, and the most important, is that these millions of tons of reserves are not equally distributed, even as they have been in normal times in the past. The railroads are particularly short of stocks. Their supply on Oct. 1 is reported as 5,450,000 tons, a 15-day supply, or only half the normal 30-day reserve at this time of the year. Locally this will have an important bearing on the situation as soon as zero weather, long delayed in the northern areas, arrives. Nothing plays hob with coal distribution like confiscation by the railroads when they have to resort to such tactics for protection.

Current market reports record the steady demand for domestic sizes and bear out the conclusion of the Survey that retail dealers have low stocks. For the past month lump coal has been at a premium and the resultant sizes of steam coal are in oversupply. This situation will not be cleared up until industrials, particularly in the regions adjacent to the mines in the Middle West, take it upon themselves to resume stocking. Every indication is that the pressure for domestic coals will continue heavy throughout the winter. Railroad-fuel demands in this territory, however, will curtail the supply of lump that can be applied on this business.

The iron and steel industry, requiring a large volume of special coal and with but half a month's reserve on Oct. 1, which by the way is not far below normal, is working with renewed activity. Though reserves of coal are not dangerously low, the stocks of byproduct coke on hand are reported as but one-fourth those in March and it seems apparent that there can be no falling off in this important market. With respect to steam coal New England has been in a comfortable position all year and it is now apparent that the Northwest will have little trouble on that score this winter.

On the whole the feeling of relief that the crisis is past is warranted. A month's average reserve is insurance against a panic market, but it is at least 10,000,000 tons below the normal supply in the hands of consumers at this time of year. Offsetting the inequality of its distribution is the fact that the most distant markets are best supplied, which means that acute local trouble will be largely confined to consumers near the mines and thus able to get coal by rail without delay save when storms interfere. Severe weather is inevitable. Industry is gaining in activity. There is no likelihood that the coal market will fall flat this winter. Healthy activity will be better for all than a runaway market.

Making Strikes Unnecessary

WITH an April strike hanging over its head, the country is told by the United Mine Workers that the causes of strikes lie between the arrogance of mine officials and the refusals of the operators to meet the miners in the negotiation of wage settlements. In the second of its communications to the Coal Commission in answer to a general request for information on the causes of strikes and suggestions for their prevention, the committee of the miners' union urges complete unionization of the coal fields as the only true solution of the coal problem. The miners point out that the coal miner is the best striker in the world and say that they desire not that strikes be made impossible, but unnecessary.

It is not conceivable that the union in presenting these two communications to the commission has any idea that they will be taken seriously. These "releases" are too obviously releases for the press—the last for support of the press in the suggestion that newspaper reporters be used as investigators is evidence in point. The commission has too patent an opportunity for checking the loose statements of the miners to cause any concern to those who desire that the facts be known.

In respect to the last two general strikes the commission may conceivably go behind the record and concern itself with the basic causes; it may not contend itself with the loose assertion that the miners had to strike because they could not learn what wage they would be offered when their contract expired. There is more than the turning of a phrase in the statement of the bituminous-coal operators that absentee control of mine labor is a prominent factor in general strikes. But then the overlordship of labor exercised by John L. Lewis is more a thing to be cursed by the soft-coal operators than otherwise. The solution of the labor problem here is a control of that leadership in the public interest and not its complete abolition. It is fatuous to suppose that the union among the coal-mine workers can be eliminated.

Since the public, and hence the Coal Commission, is chiefly interested in strikes as they affect the supply and price of coal, local strikes are of minor importance. Every industry that is organized has petty strikes, the building trades being a particular case in point. Dis-

valve at individual mines are common, and all too frequently these end in strikes in contravention of the contract between the company and the men. The United Mine Workers are maintaining that the officials of the coal companies are responsible for these outbursts. The fact of the matter is that the very nature of the relations between the producing company and the contract miner is such that constant adjustment is required in respect to matters of payment for work. No contract has ever been written that makes provision for every contingency. The foreman who is responsible for results and costs is no more anxious to get work done as cheaply as possible than is the miner to get all he can for what he does.

We venture to say that the promotion of a miner to foreman changes his viewpoint only and not his human nature. The complaint of the United Mine Workers that petty strikes are solely the result of arrogance on the part of minor officials is a one-sided statement. It is not borne out by the facts. Time and experience in the coal mines have produced a system of carrying upward the petty troubles between miner and underofficial. It is set forth in the contract, and in most instances conciliation prevents open rupture and a strike.

Where local strikes become common, as in the Middle West in recent years, there must be some underlying cause beyond the mere personalities of the mine officials. Plainly enough the irresponsibility of the miners toward their contracts has been increasing. There have been notorious but comparatively rare instances where individual operators have violated the contract by paying bonuses over the agreed scale of wages. In general, however, it is the union miner who in recent years has shown the greatest contempt for his contract, and until he can be made to respect his obligations in full, and act at his convenience, there will be local as well as general strikes.

Investigating Profits of Coal Industry for Last Ten Years

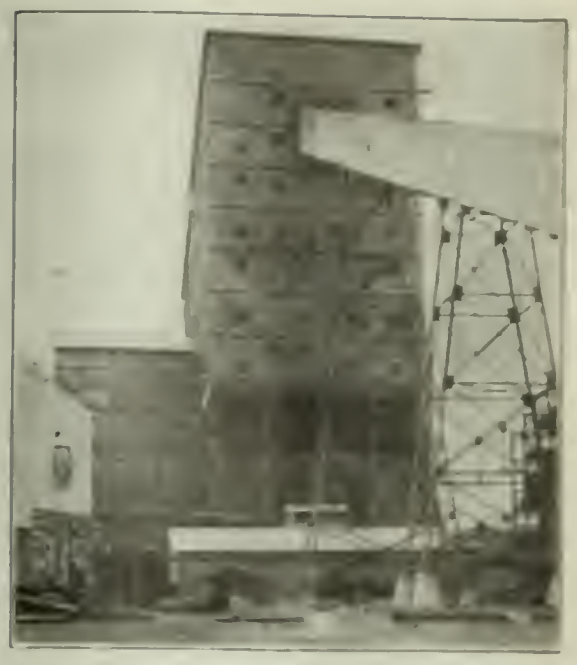
IN FRAMING the act under which the coal commissioner is presenting Congress said that the profits of the coal industry for the last *ten years* should be investigated. The coal industry, particularly the bituminous-coal men, should be thankful that ten years and not five was specified. On the whole the last five years have been the most profitable ever enjoyed by the coal industry. They have, furthermore, been the only five-year period in which the coal operators had any real idea of costs and profits. Prior to the war the coal company that had a real set of books on which were charged more than actual out-of-pocket expenses was an exception. Depletion, and in particular depletion of leaseholds, and depreciation were unknown accounts, little understood and, for that reason, generally neglected.

The commissioner has no choice in the matter of calling on the coal companies for a ten-year record, for the law says that it shall be done. The coal companies should be keen on giving that record. They should spare no expense in putting their books for the entire period on a comparable basis, setting up accounts for depletion and depreciation and other omitted items in the earlier years. If they fooled themselves ten years ago as to what they were making on their operations that is no reason for perpetuating the error. That no charge was made for depreciation in the earlier part of that period on the accounts as then kept does not mean that that figure did not exist as a charge.

The auditors and bookkeepers of every company should at once begin a study of the old records and be prepared to give the commission these reports when it calls for them, as it must. To look over the records of the past will cause much painful reminiscing but it were well that the facts be known.

Mine Transportation

AS THE mine hauls lengthen, the business of mining more and more approaches that of railroading. Those who realize it earliest will profit most from that knowledge. The railroads have failed because they have not been kept in condition. The mines accordingly have suffered a shortage in car supply. Conditions are little better below ground. Car supply at the face is short because the underground railroads have been allowed to run down and are inadequate.



It may yet be that we shall see roads ten and more miles long with separate transportation officials. This arrangement will be the only way of giving transportation its due emphasis. Mines already have hauls four to five miles long; there may be some even longer. As much as ten years back there was a mine in Wyoming having a five-mile haul. There are some in central Pennsylvania equally long. It would be interesting to get figures on this subject.

What is being done to meet these difficult problems? One company, the Cambria Steel Co., has laid 70-lb. rail and introduced a 35-ton locomotive. Another, suddenly waking up to the idea that its transportation problem overshadowed that of mining, replaced its light rail with rail of like weight to that of the mine to which reference has been made. Some of the anthracite mines are using limestone ballast. Other companies are introducing a bedding of field stone. Many old stone fences in farming and mining regions have already found their way underground. Train dispatching is being introduced, and cars are being made having spring draft rigging and even axles with spring boxings. Some companies no longer wait till cars are ditched to examine them but keep them under constant inspection. Others follow railroad methods in the inspection and laying off of locomotives. Bonding and feed-wire erection are improving. Tracks are better lined and graded.

About eight years ago at a meeting of the Coal Mining Institute of America someone said something about transportation problems around the mines and a general laugh greeted the suggestion that the mine had any transportation problems of its own apart from railroad transportation. The leading superintendents of today realize that they have a real railroad system underground, and the very recognition of that fact is a cure for many of the mining evils with which they had formerly contended. One superintendent who realized that the main problem of his mine was transportation was able to convert that operation from a dismal failure to a conspicuous success. There is a distinct value in calling a spade a spade. It sometimes solves your problems for you. In some of our mines with insufficient superintendence to call the mine tracks a "railroad" would in a month or two develop an individual known as the "road superintendent" and in a few months later a road that would make haulage both cheaper and more speedy.

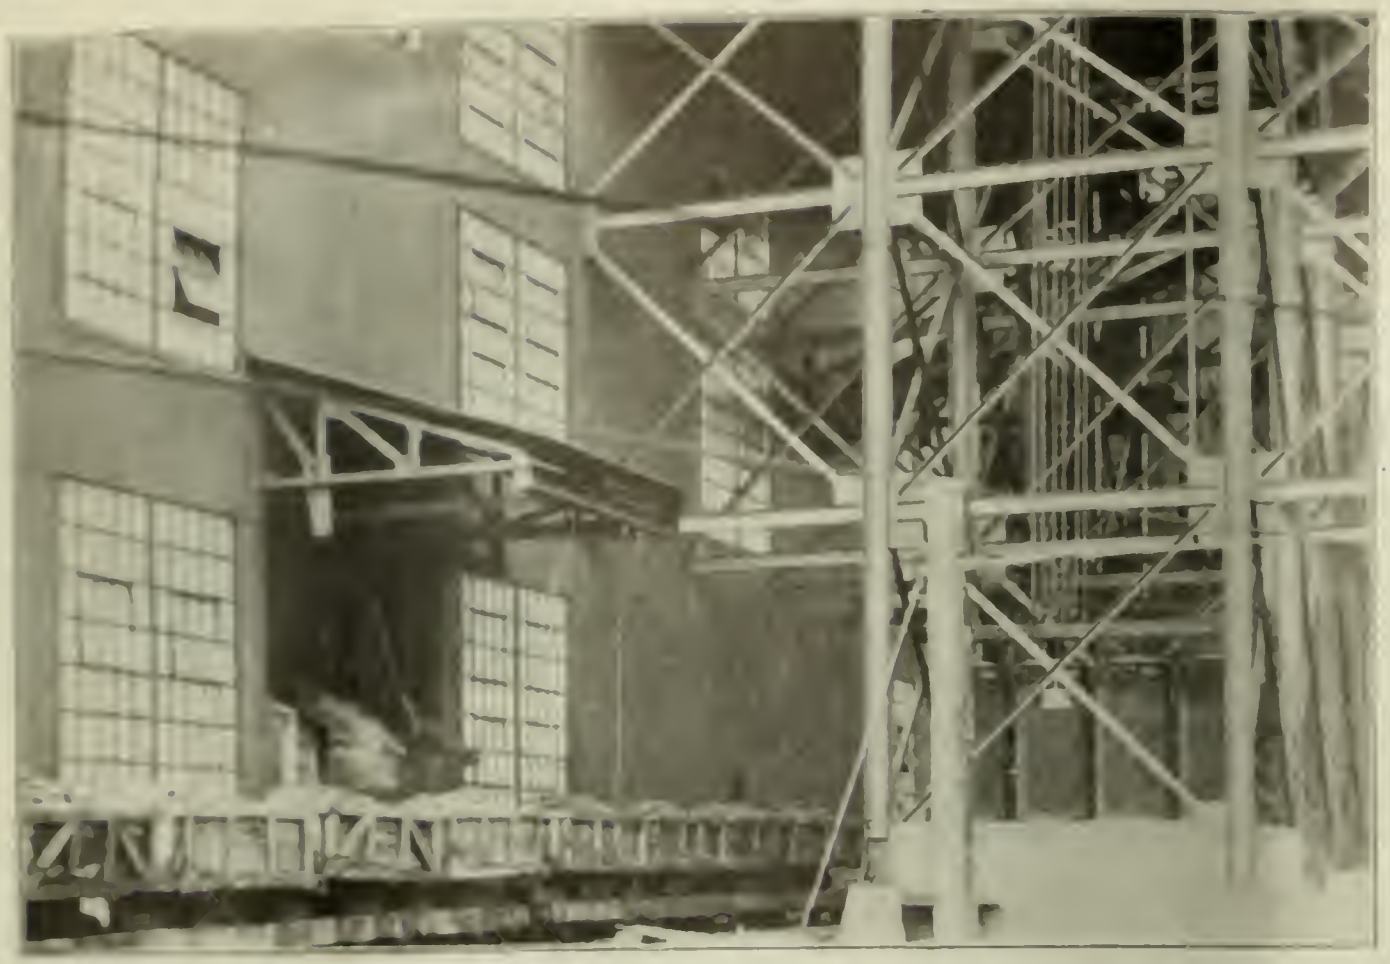
Dunmore Breaker Makes A Specialty of Grate or Broken Coal

BY DEVER C. ASHMEAD*
Kingston, Pa

Pennsylvania Coal Co.'s Fireproof Preparator—Lump and Steamboat, Still Dry, Are Picked on Table by Sixteen Men—Protection of Rock Chutes—Screen Areas Provided—Clay Pipe for Carrying Fine Coal

At No. 1 colliery of the Pennsylvania Coal Co., Dunmore, Pa., just outside the City of Scranton, a new breaker has been completed, regarding which a preliminary and incomplete description was given in the paper entitled "Advances in the Preparation of Anthracite," read before the American Institute of Mining and Metallurgical Engineers and appearing in Volume 56 of the *Transactions*.

Since this paper was written the breaker has been finished. It went into operation on Sept. 11, 1922, at the conclusion of the anthracite mine strike. The building is constructed entirely of steel, concrete and glass. Wood was used only for the lining of the loading pockets and the construction of the jigs. The building is as fireproof as it is possible to make a structure of this kind.



*Anthracite Field Editor, *Coal Age*

Some features about the building are of considerable interest, differing from those in most of the other breakers in the anthracite field. At this preparator a specialty is made of grate, or broken, coal. The coal is not wetted before it reaches the bull shakers at the top of the breaker but is allowed to pass in a dry condition from the bull shakers to the picking table, where sixteen men carefully remove all loose slate and chip off whatever may be found adhering to the large pieces of coal. Another feature somewhat peculiar to this breaker is that the rock chutes are so designed that only pieces of rock less than 8 in. square can travel down them. The miners are not supposed to put in their cars any slate larger than the size specified.

By thus limiting the size of rock that the chutes will handle these transportation ways are considerably reduced in size and can be made less heavy. Furthermore,

No. 1 Breaker

Terminal Rock Loading Chutes

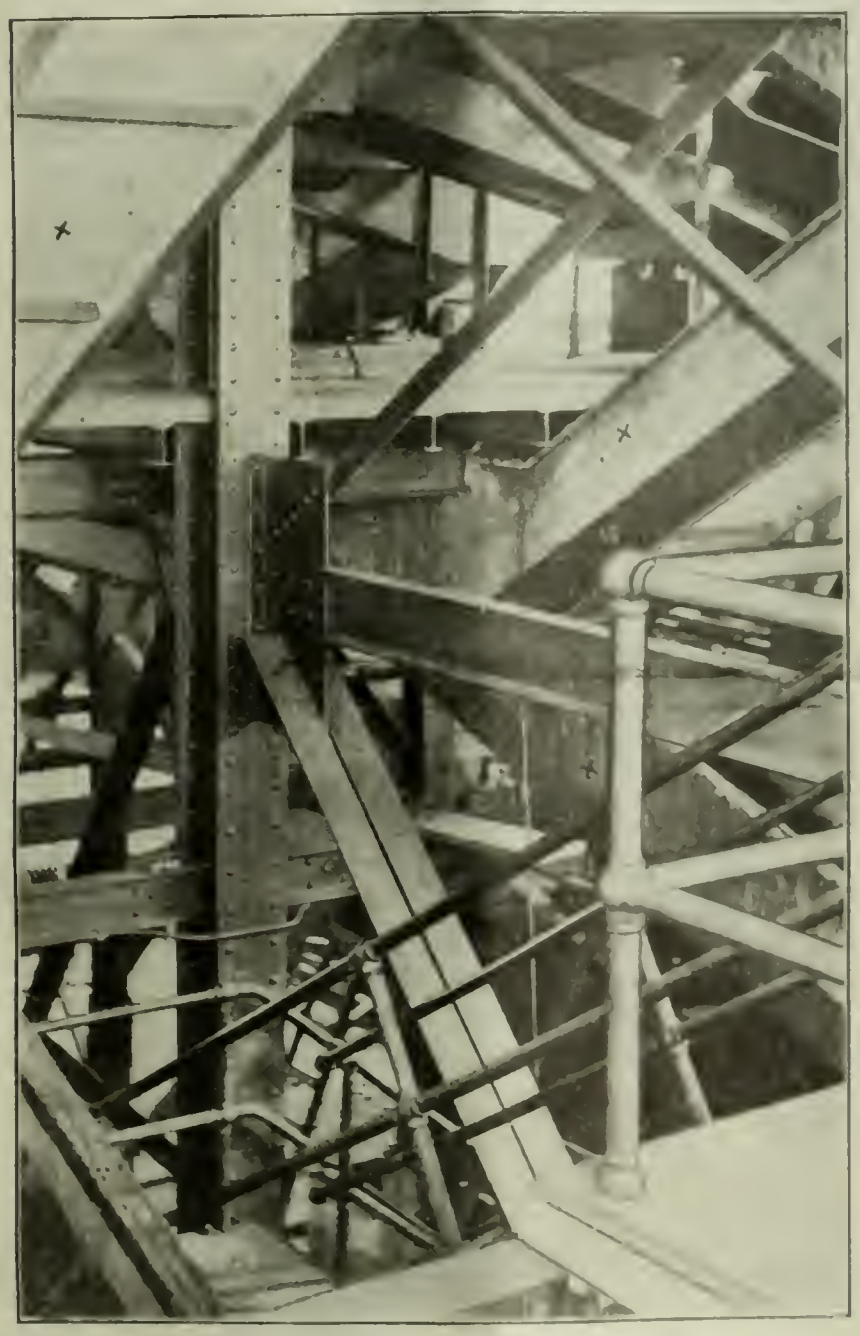
The rock is all under 6 in. in diameter, as the chutes are not made so that they will accommodate any larger size. Bigger rock is accordingly left in the mines. This provision makes it possible to use rock chutes of lighter weight than is usual. An electric locomotive hauls the rock cars to the rock dump for disposal. Note the transformers on a platform to the right.

small rock can be better inspected than large when it gets to the rock shakers.

The breaker drive is not centered in a single unit but consists of several motors: One of 200 hp. is used to drive the main dragline conveyer and six of 100 hp. actuate the shakers and the jigs. There also are three 25-hp. motors, making a total of 875 hp. installed.

Designed to handle an output of 4,000 tons in eight hours, the breaker has not as yet reached its capacity, but the output during the early part of October ran consistently at about 3,000 tons per day of eight hours. The areas of the shaker screens are as follows: The lumpcoal deck has 90 sq. ft. of screening surface; the grate or brokencoal, 225 sq. ft.; the egg-coal, 609 sq. ft.; the stovecoal, 360 sq. ft.; the chestnut-coal, 648 sq. ft.; the pea-coal, 180 sq.ft.; the No. 1 buckwheat-coal, 180 sq. ft.; the rice-coal, 216 sq. ft., and the barley-coal also 216 sq. ft.

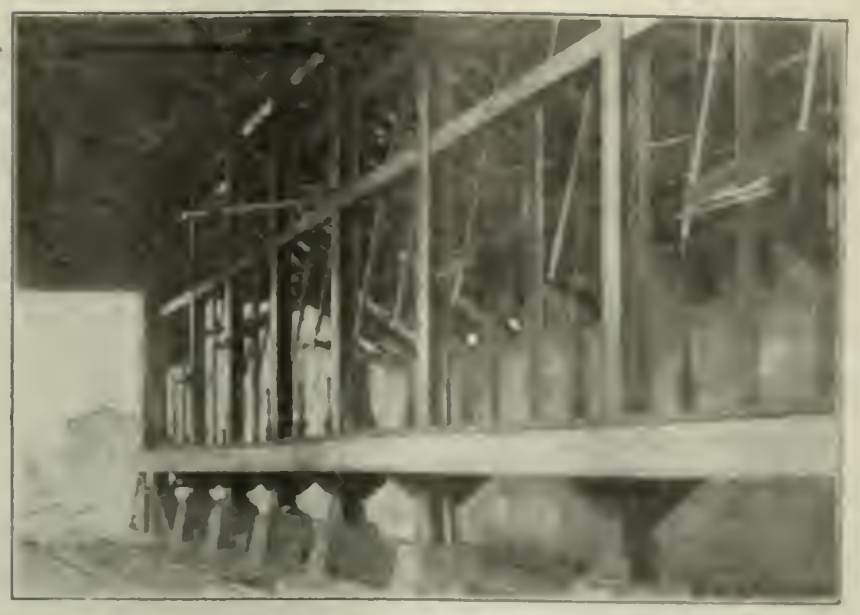
In some places in the breaker the chutes are lined with vitrified clay pipe, and this is applied in an unusual way. In the first place a concrete chute was constructed somewhat larger than the half section of the vitrified clay pipe. The pipe was then installed and grouted into place. A distance of from $\frac{1}{4}$ to $\frac{3}{4}$ in. was left between the joints of the pipe lining.



It is doubtful whether this arrangement will prove satisfactory in practice, as the grout is not as hard as the glazed surface of the pipe. In consequence it is likely to be abraded, and then the pipe will be attacked from the edge, and as a result will wear abnormally.

Foot of Conveyor

It would seem that a longer life would be obtained if the sections of the vitrified clay pipe were laid tight against each other. One of the accompanying illustrations shows this pipe and the construction of the chutes. All the boiler coal is weighed by a fuel meter.



The loss of coal from spillage at the average breaker is considerable. When the railroad cars are loaded some coal will inevitably be spilled either over the top of the car or through leaks in its bottom or sides which have not been properly stopped. This coal usually collects on the ground around the loading pockets until it is finally removed by a man with a hand shovel. Arrangements were made in designing this breaker to avoid this labor. The floors under the loading chutes and the bottom of the breaker have been built of concrete and so arranged that they drain to one point. It is possible, therefore, at this plant to wash all the coal spilled in loading to a tank where the coal settles out of the water and is removed by a dragline conveyor which takes it to the condemned-coal conveyor, whence it is sent through the breaker for re-treatment.

CONCRETE CHUTES WITH VITRIFIED-PIPE LINING

Chutes marked with a cross are of vitrified pipe set in a concrete base. The upper surface of one of these pipe chutes can be seen in the lower left-hand corner. Such chutes are not only fireproof but in some degree serve to stiffen the building in which they are used.

One of the accompanying illustrations shows the flow sheet of the Pennsylvania No. 1 breaker. The figures in the accompanying text refer to those on the illustration. When it comes from the mine the coal goes to

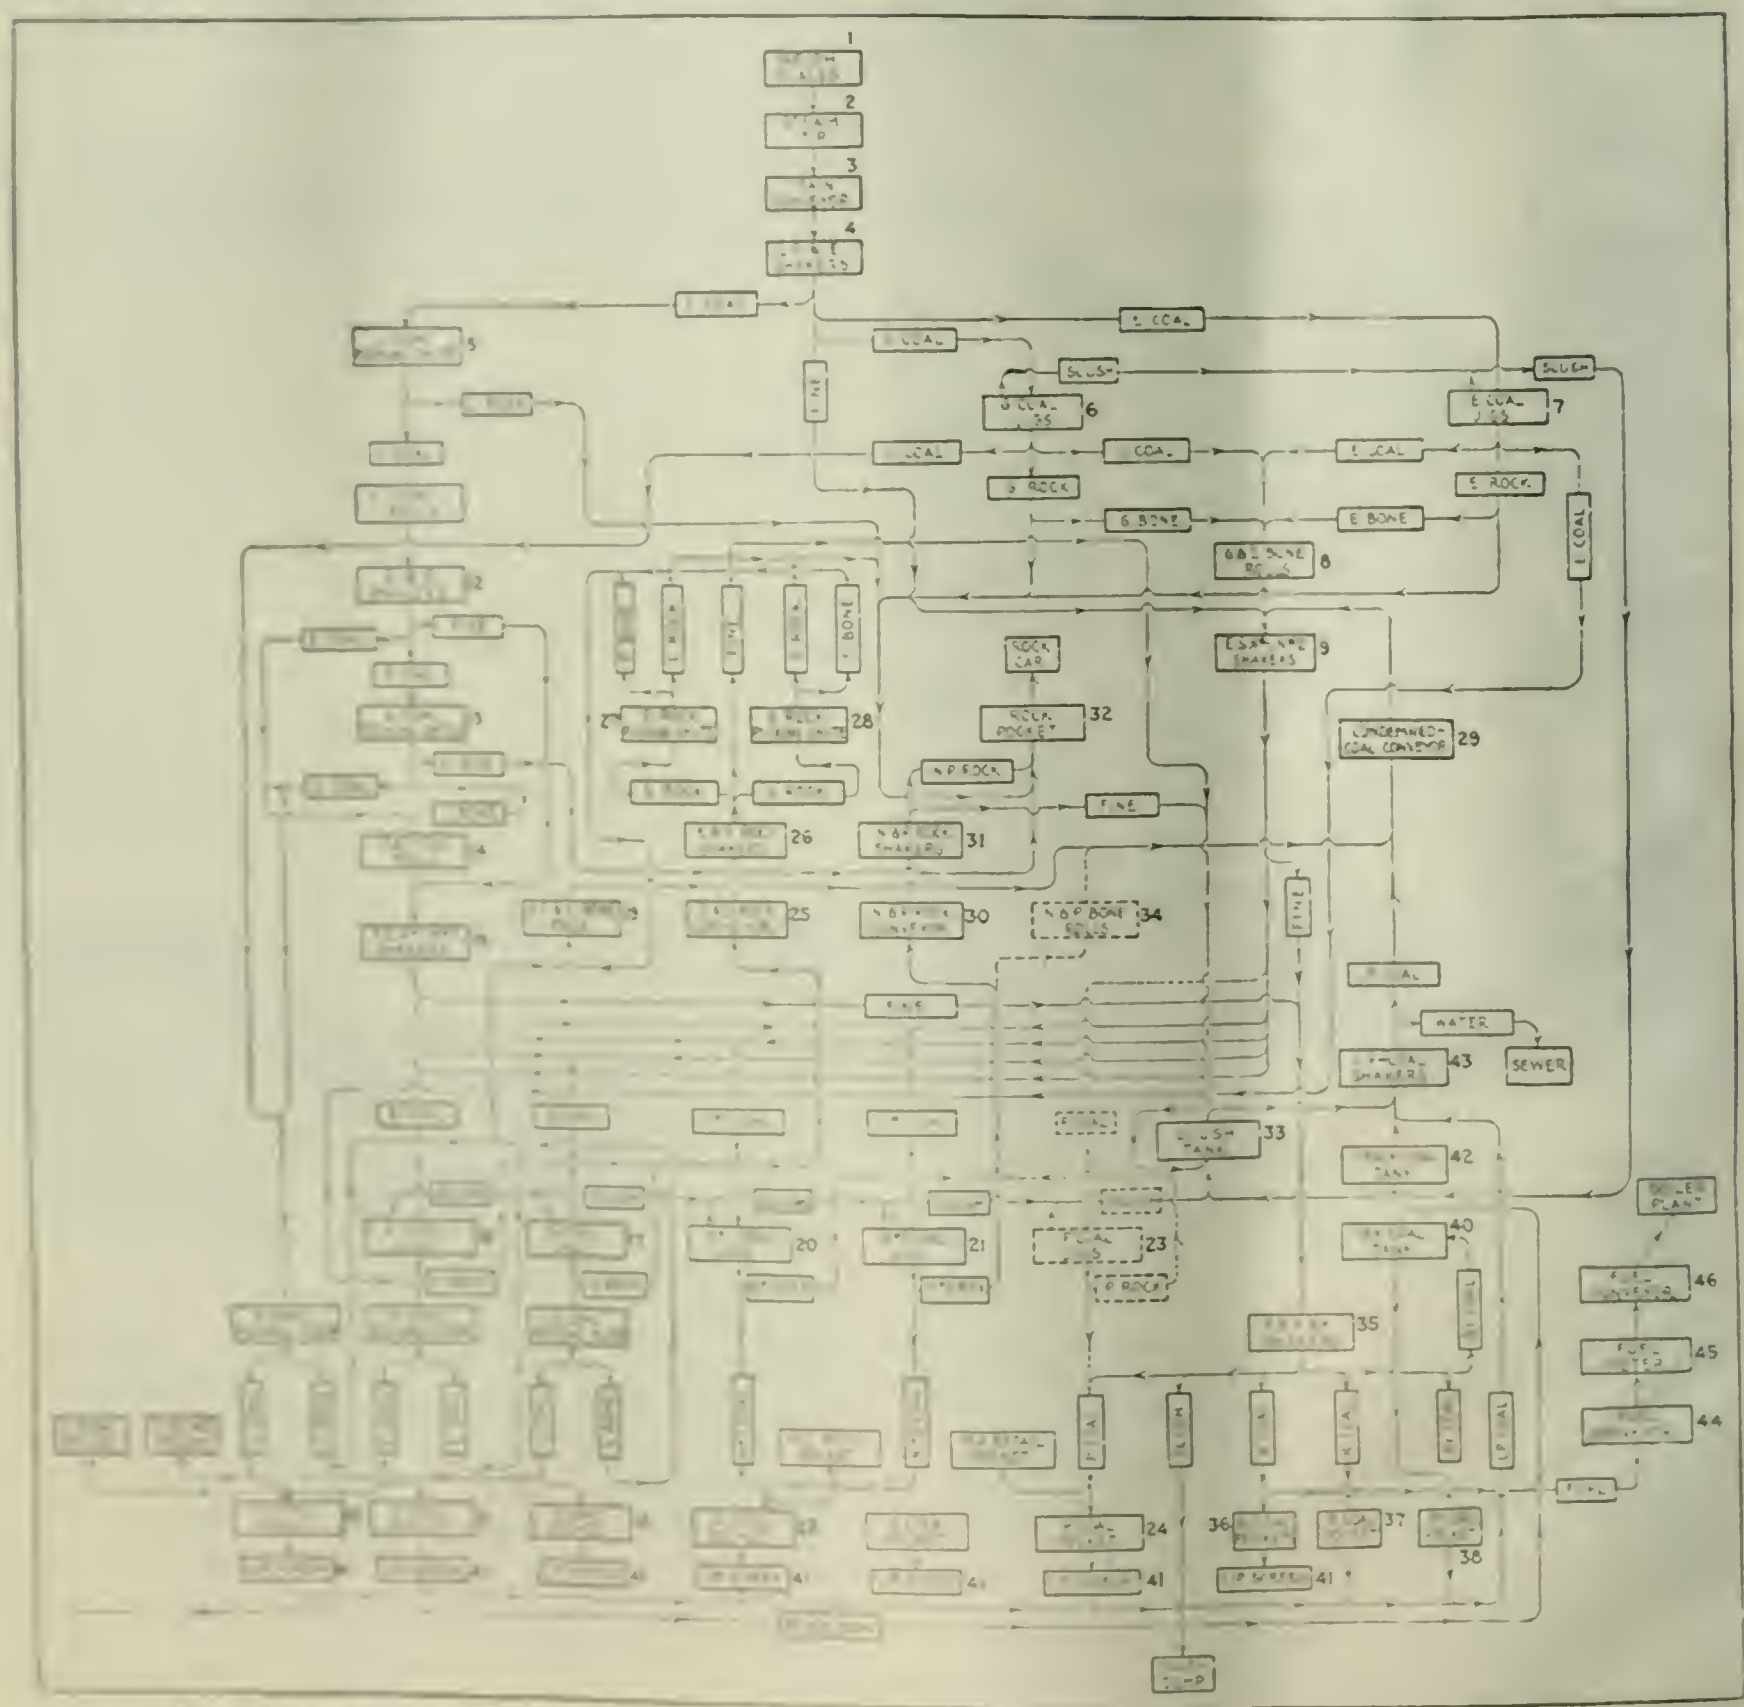
NO WASTE OF COAL AT THE LOADING POCKETS

The floor of this section of the breaker is of concrete and so arranged that any coal spilt can be washed to a tank below the track and sent back through the breaker for preparation.

the foot of the main conveyor. Here the coal is weighed (1) and the mine cars are dumped by means of a steam dump (2). The coal is then taken to the top of the breaker by means of a Wilmot chain conveyor (3) which measures 385 ft. between centers and has 12-in. joint pins. The flights are 5 ft. apart and 4 ft. wide. It has an estimated capacity of 4,000 tons in eight hours.

When the coal leaves the conveyor it is dumped into a chute leading to the three-deck, main, or bull, shakers (4) in the top of the breaker. The lump coal, which includes the steamboat, passes to a picking chute (5) and is here picked by sixteen men. The coal is kept dry until it is hand picked. Thus the pickers are aided in distinguishing between slate and coal. The broken and egg coal which is taken from the second and third decks of the main shakers (4) pass directly to Elmore jigs (6 and 7). The rock from these jigs is hand picked to remove coal and bone, the latter being sent to the bone rolls (8), from which the crushed material passes to another shaker (9) which makes egg, stove and two sizes of chestnut coal. The coal from the jigs then passes to the picking floor, where the lump left

DRIVING MECHANISM FOR BELT CONVEYOR



A flywheel is mounted on the driving shaft to offset pulsations caused by the belt.

to the coal will be removed. The cleaned product goes directly to the pockets (10 and 11).

Cleaned lump coal from the picking chute (5) goes through the main rolls, and thence to a set of broken, or grate, and egg shakers (12). Grate coal then passes to a picking chute (13) and unites with the egg coal and passes through the rolls (14). Thence it passes to another set of shakers (15) on which egg, stove and two sizes of chestnut are made. The egg, stove and chestnut coal then goes to Wilmot jigs. After cleaning the coal in the jigs, it passes from the egg jigs (16) and the stove jigs (17) and is then hand picked, the cleaned product going to the proper pockets (11 and 18). Bone coal recovered in handpicking the grate, egg and stove coals unites and goes through rolls (19), the crushed product of which will be carried by the condemned-coal conveyor (29) to the shaker (9).

Cleaned coal from jigs (20 and 21) which treat the two sizes of chestnut coal, after uniting, go to the nut pocket (22). Shaker (9) is so arranged that the bottom deck can be changed to produce pea coal; in that case this size passes to the pea jigs (23), the cleaned product of which will go to the pocket (24).

Rock from the egg and stove jigs (16 and 17) unites and is taken by the egg-and-stove rock conveyor (25) to the egg-and-stove rock shakers (26). Here it is separated, after which the bone is hand picked (27 and 28) from the rock and is sent to the grate, egg and stove bone rolls (19), and thence to the condemned-coal conveyor (29). The rock from the chestnut and pea jigs (20, 21 and 23) unites and goes to the chestnut-and-pea rock conveyor (30), thence to a shaker (31), where the fines are removed. The rock then goes to the rock pocket (32) and the fines to the slush tank (33). Instead of sending this rock from the chestnut and pea jigs (20, 21 and 23) to the rock conveyor (30),

FLOW SHEET OF BARKER-GOODWIN WHOLE PREPARATION PROCESS AND LOADING PROVISIONS

[illegible] nut; P [illegible] pea, No. 1 and No. [illegible]
[illegible] washed after washing

Wilmot Jigs

In this battery of jigs, egg, stove, chestnut and pea coals are cleaned. The spiral chute to the left conveys the broken coal prepared near the top of the breaker to the pocket near the railroad track. It will be of interest to compare the light, uninflammable walls of this breaker with those of the old wooden structures which formerly were all the anthracite region knew. With the old breakers it was difficult to distinguish coal from slate under the unfavorable light conditions obtaining.

however, it can be sent to the chestnut and pea rolls (34), from which the resulting product is sent to the condemned-coal conveyor (29).

All of the fine coal from shakers (9 and 15) unites and passes to shaker (35), where pea, No. 1 buckwheat, rice, barley and slush are separated. The sized coals without further treatment pass directly to their respective pockets (37 and 38), the slush going to the slush dump (39). The barley coal can be sent from the shaker (35) to the barley tank (40) on its way to the pocket (38). All the slush from the Elmore jigs near the top of the breaker and from the Wilmot jig passes to the slush tank (33).

As already stated, the coal spilled is washed to the track-coal tank (42). All the lip-screen coal (41) is taken to shaker (43) on which it is joined by the track-tank coal. Here the water is separated from it. The coal is then delivered to the condemned-coal conveyor, which takes it back through the breaker for re-treatment.

The buckwheat, rice and barley sizes, instead of going to their respective pockets after being screened

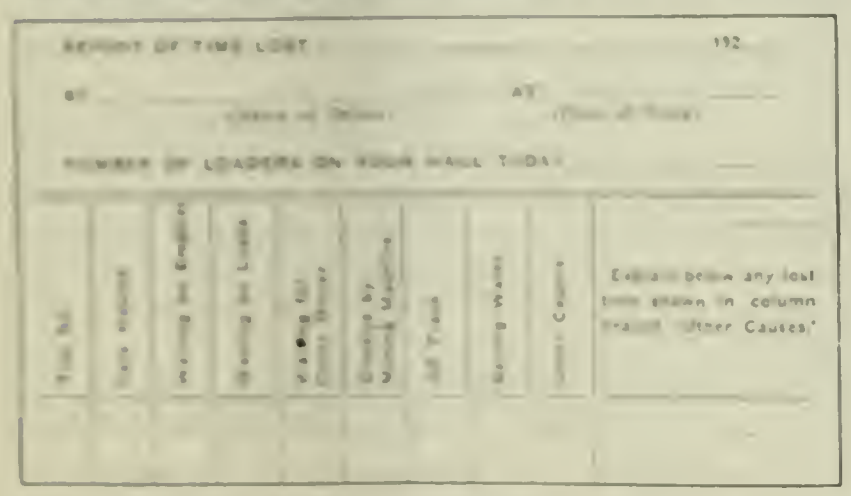
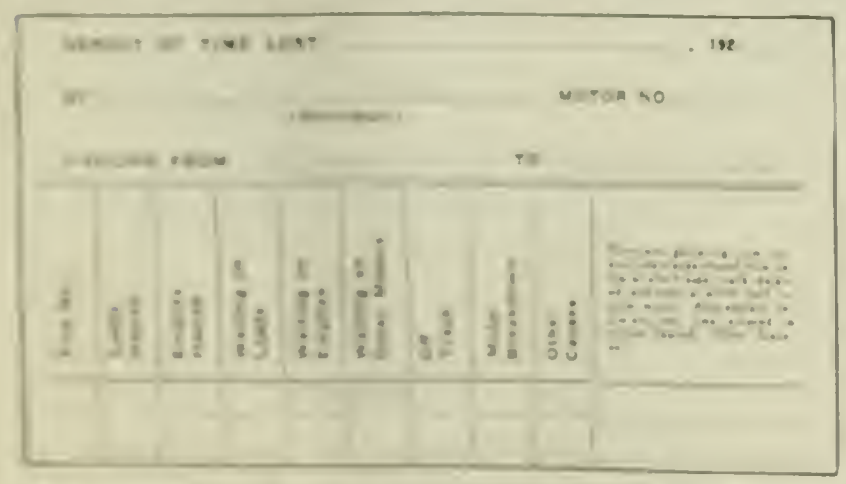
economy in itself will give a considerable return on the cost of construction of the new breaker, which is estimated to have been between $800,000 and $900,000.



Every new breaker shows a large saving over previous breakers. This one is certainly no exception to that rule and the saving in this instance would be more marked were it not for the fact that a special grade of coal is required at this breaker. Except for this it is possible that many of the sixteen platemen now employed might be dispensed with.



Reporting Delays Lowers Production Costs

By George Edwards

AN IMPORTANT item of expense in coal-mining operations is delays. It is a common occurrence at the average coal mine for the tipple to be waiting on coal, the main-haulage locomotive standing idle at the main sidetrack, and at other times the gathering locomotives and mules waiting on the main-line locomotive.

The explanation that usually will be given on inquiry is that the delay has lasted only a few minutes. Further questioning brings one no closer to the real trouble.

DELAY REPORTS FOR INDIVIDUAL MOTORMEN AND DRIVERS

for it is a common failing with most of us to blame delays or other failures on someone else.

Recently at a new and modern mine, where preparations are being made to handle a large tonnage, 12 minutes was lost while a car of slack was being moved and another car was being placed under the chute. The most common delay on main-haulage roads is derailments, inconvenient switching room inside and out, and frequently failure to move the trips owing to the desire to haul longer trips than the locomotive can handle.

A boss newly engaged recently found that the main-line motors had perpetual trouble in moving their trips. He decided on smaller trips and more of them, and his plan resulted in an immediate increase in production.

But the bane of the gathering crews' existence is derailments and lack of space to get around the mine cars and trips easily and speedily, the latter trouble being due to low entries and to roadways narrowed along the clearance side by standing posts and timber sets and by loose material such as ties, rails, posts, slate and coal laid alongside the tracks. This is often the first fault to be rectified.

A good plan when studying delays is to have "delay reports" made out daily by drivers, motormen, tippleman and others for a month or more at a time. In this way the causes of delay of every kind can be placed where they belong. The attached reports, used periodically by the North East Coal Co., in Kentucky, have proven to be most valuable in locating trouble and keeping everybody moving

Disk Fan Actually Made from Metal Disks

A DISK fan usually is a machine built up with the aid of rivets. The illustration shows one that actually is made out of two disks by merely cutting the fan radially and pressing into fan blades the sixteen sectors thus formed. The two disks are placed back to back and riveted together, forming a wheel 5 ft. in diameter. The blades overlap one-half their width for their entire length. The bearings are collar oiled and are proof against suction, which sometimes draws out the lubricant. The fan is made by the Pittsburgh Fan & Manufacturing Co., Bessemer Building, Pittsburgh, Pa.

PRESSED-STEEL DISK FAN

This fan is made by merely cutting and pressing two disks (which have been riveted together) so as to form blades.

Temple Coal Co. Supplements Its Breathing Apparatus With Mask That Absorbs All Poisons in Mine Air

In Devitalized Air Oxygen-Breathing Equipment Alone Can Be Used, but in Many Cases Where a Safety Lamp Will Burn, Work Can Be Done Safely in the Right Kind of Mask

By Dever C. Ashmead*
Kingston, Pa.

IN PRACTICALLY all parts of the anthracite fields one of the great dangers of mining is from the emission of gas. No matter what ventilating precautions are taken, how completely safety lamps, electric and flame. are furnished, how closely the men are inspected to see if they are carrying matches beyond danger points, or how rigorously the working places themselves are inspected, gas explosions will occur as long as man mines coal.

With the danger of these explosions always in mind coal-company officials in the anthracite region have established rescue stations at the various collieries. One of the most modern and well-equipped of these is that of the Temple Coal Co. at its Mount Lookout Colliery, near Pittston, Pa.

This station has six Gibbs oxygen apparatus, Edison electric lamps, Wolf safety lamps, carbon-monoxide detectors, an oxygen pump and cylinders, a mercury manometer for testing apparatus, a resuscitating device and six Burrell all-service gas masks.

After an explosion of methane, afterdamp is formed, which consists of oxygen, nitrogen, methane, carbon dioxide and carbon monoxide. In many cases enough oxygen is present to support life, but, unfortunately, it is not possible for a man to live in an atmosphere that contains much carbon monoxide. In consequence men who have hitherto engaged in rescue work have had to wear a helmet that would provide them with oxygen and would also exclude from the atmosphere they breathed any carbon monoxide.

*Anthracite Field Editor, *Coal Age*.

After a long series of experiments a chemical known as hopcalite has been discovered that will change carbon monoxide into carbon dioxide. It is used in the all-service gas mask. This chemical, together with charcoal and calcium chloride, is placed in a canister which is shown hanging from the necks of the men in one of the illustrations.

Air is admitted through the bottom of the canister and as it passes through the charcoal it is filtered, the smoke being absorbed with any ammonia gases which it may contain. It then passes through the calcium chloride, which absorbs the moisture, and then through the hopcalite, which changes the carbon monoxide into carbon dioxide. Again the air passes through calcium chloride and then through another layer of charcoal, and then into a timing device. Sufficient hopcalite is provided in the canister to last for two hours.

With each breath the timer is actuated. The breath operates a small valve which revolves an indicator in a clockwise direction around a dial. This action is automatic, the position of the dial indicating the length of time the canister has been used and of course the length of time that canister can be worn before being recharged. Each canister is good for a two-hour period of actual service, whether worn intermittently or continuously.

One important feature is that the air of the mine is dried in the canister and is so deflected that it strikes the lenses of the face mask so that they remain clear under all conditions. This deflecting of the dry air against the lenses removes all moisture that might be

Gas-Mask Crew

These men are fitted with gas masks which can be used for two hours in any afterdamp mixture so long as there are breathable quantities of oxygen present in the air. Thus the mask may be worn wherever a light will burn. The hopcalite used in the mask has the power of rendering a certain quantity of carbon monoxide harmless by oxidizing that gas and forming carbon dioxide.

RESCUE CREW AT MINES OF THE TEMPLE COAL CO. AT MOUNT LOOKOUT COLLIERY, NEAR PITTSTON, PA.
At this colliery six oxygen apparatus, six all-service gas masks, several electric lamps, safety lamps, carbon-monoxide detectors, an oxygen pump and cylinders and a resuscitating device are kept ready in case of accident.

deprived by the exhaled air. The air passes out through the exhalation valve, which opens on exhalation and closes upon inhalation, so that the wearer gets absolutely fresh air at each breath.

The mask gives all the protection a self-contained oxygen apparatus will give, provided enough oxygen is present in the surrounding atmosphere to support the flame in a flame safety lamp. In other words a flame safety lamp is the guide in knowing how far to travel, for it indicates when a point has been reached at which the oxygen content of the atmosphere is too low to support life under exertion. The safety lamp will be extinguished when the oxygen in the air falls as low as 16 per cent. As a man can live in an atmosphere which contains as little as 12 to 13 per cent of oxygen the indication of the expiring flame of the safety lamp affords a liberal factor of safety. As the hopcalite is not affected by a change in temperature, the mask will furnish protection regardless of the heat or cold to which it is exposed during or before service.

Gas Mask Has Advantage of Lightness in Weight

The Burrell gas mask has another advantage over the oxygen apparatus. It is extremely light, weighing only 3½ lb. Thus the wearer can do heavy work and not become as fatigued as when wearing the oxygen-breathing apparatus. The gas mask is particularly valuable in re-establishing ventilation and for exploration work, particularly in advance of the working gangs. Members of the rescue crew also can use this type of mask in keeping open communications with the oxygen-apparatus squad and the base of operation at the foot of the shaft.

EQUIPMENT ROOM OF RESCUE STATION
In this compartment can be seen the oxygen tanks and on the shelves, boxes and frames containing the masks and various apparatus. Above the door is a mirror for inspecting the latter before leaving the station.

In making preliminary explorations of mine fires it would be quite helpful, for it would permit the superintendent or mine foreman to make his preliminary explorations of the conflagration without exposing himself, as such men too often do, to the danger of carbon-monoxide poisoning.

A few gas masks of this kind kept in the mine might serve pumpmen, stablemen and others well should a fire break out during an off shift when they alone are on duty. It would practically assure their arriving at the surface in condition to report the occurrence of the fire. Another purpose for which it might be valuable is in protecting shotfirers and firebosses from monoxide poisoning. Misfires often occur which set fire to the working places. A gas mask of the all-service type would permit the shotfirers to make explorations in safety despite the heavy smoke that arises from such fires.

Keeping the Storage Battery Young and Lively

Danger of Manual Adjustment in Charging Lead Battery—Disadvantages of True Constant-Potential Charging—Modified Constant Potential with 2.6 Volts per Cell and Fixed Series Resistor Recommended for Lead Battery

By M. F. Packard*
East Pittsburgh, Pa.

Too much emphasis cannot be placed on careful charging, for the life and performance of the storage battery are so largely dependent on the way in which this work is done. Ignorance of the requirements and carelessness in their fulfillment are responsible for most premature battery failures. For this reason this article will discuss the charging problem, indicating the advantages and disadvantages of various methods, so that the one best adapted for a given condition may be selected. Only the vital phases can be discussed and then only briefly, for the subject is a lengthy one.

In charging a lead battery it is of greatest importance to avoid gassing at high charging rates and to keep the cell temperature below 110 deg. F. Until the prescribed finishing rate is reached these requirements are fulfilled by adjusting the charging rate in amperes to a value at all times less than the ampere hours out of the battery. The locomotive should be equipped with a reliable ampere-hour meter, which will indicate the ampere hours out of the battery and be a guide in determining the discharge limit.

The ampere-hour meter is designed to run slow on charge and when used on a lead battery should be adjusted so that about 15 per cent more ampere hours will be returned than were taken out. The ampere-hour efficiency varies somewhat with the battery construction and charging conditions, so it may be found necessary to depart a little from the figure given. The meter may be readily adjusted, however, and a few trials will determine the best setting. The battery-compartment cover must be left open throughout the charge, so that the highly explosive gases that are given off by the battery during part of the charge can escape freely. No lighted tobacco, matches or other exposed fire or sparks should be allowed in the vicinity of the battery while it is being charged.

In the past the charging current has been adjusted quite extensively by hand, but when the charge was thus regulated the battery frequently was damaged severely in consequence of the ignorance or carelessness of the attendant. It is seldom practicable to hold the ampere input equal to the ampere hours out of the battery, as this involves too constant attention, and there are objections to the size of the equipment needed, as will be shown later in discussing constant-potential charging.

The usual procedure is to start the charge at a fixed rate in amperes—termed "the starting rate"—continue at this rate till the battery begins to gas, and then reduce the current to "the finishing rate," which is held to the end of the charge. All locomotive type batteries have these two rates designated and they can be approximated by occasional adjustment. The danger is that the initial rate may be continued after the battery has begun to gas violently. This dislodges the active material and causes overheating, with the destruction of the separator.

The finishing rate of charging may be continued for a reasonable time after the battery is fully charged without causing injury. The charging current is adjusted either by varying a series resistor or the field of the generator. The latter is most economical, but with series resistance less frequent adjustment is needed, as it acts as a ballast and the current may remain fairly constant if the difference between the line and battery voltages is great enough. The approximate cell voltage during a charge by this method is shown in Fig. 1, curve *A*.

An automatic charging system is greatly to be preferred to one necessitating manual adjustment and, moreover, it is entirely practicable. True constant-potential charging is automatic in so far as regulation of the charging rate is concerned, and with suitable protective apparatus no attention will be needed after the charge is started. The voltage chosen is such that the current will taper with the rising counter electromotive force of the battery and always be approximately equal to the ampere hours out of the battery.

Fig. 2 illustrates what takes place during a charge by this method. This system has several drawbacks which make its use ordinarily impractical. These are: (1) The excessive power that is required in the early stages of charging a completely discharged battery. (This makes both the investment in generating equipment and the demand charges high.) (2) The difficulty in preventing excessive voltage fluctuations and (3) the

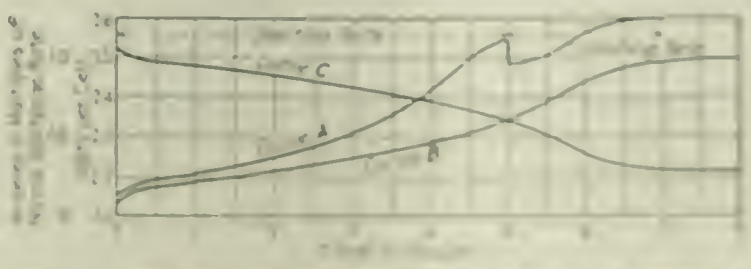

FIG. 1—CHARGING CURVES FOR LEAD BATTERY

FIG. 2—CURRENT CURVE, CONSTANT VOLTAGE CHARGE

*General engineering superintendent, Westinghouse Electric & Manufacturing Co.

necessity for adjusting bus voltage to meet seasonal temperature changes.

The simplest and safest automatic charging system probably is that called the modified constant-potential method. Best results can be obtained with a fairly uniform voltage, but fluctuations are not harmful provided adjustment is based on maximum potential, their only effect being to prolong the time required for the charge. The most suitable potential is 2.6 volts per cell, and this should be provided. A fixed series resistor also is required.

For higher voltages greater resistance must be used, and the time for a complete charge will be correspondingly lengthened. Lower voltages can be utilized, but the objectionable features of the true constant-potential system begin to arise. Typical voltage and current curves for a charge of this nature with a bus potential of approximately 2.6 volts per cell are given in Fig. 1, curves *B* and *C*. It will be observed that the current tapers as in the case of true constant - potential charging, but at no time does it exceed a permissible value. By this method the initial peak is never excessive and the charge is ended at the finishing rate or less. The charging apparatus for any of the tapering-current systems can be made so as to disconnect the battery upon power failure, to re-establish connections upon the return of power and finally open the circuit when a full charge has been given to the battery or accumulator.

FIG. 2—CHARGING DIAGRAM FOR MODIFIED CONSTANT POTENTIAL CHARGE

A failure in the voltage supplied while the battery is being charged will cause the reverse-current relay on the main bus feeders, opening the circuit and preventing the cells from discharging into the line. When power returns the magnetic contactor will reconnect the battery.

The diagram in Fig. 2 illustrates one way of accomplishing this with the modified constant-potential system. A failure of the supply voltage when the battery is on charge will cause the reverse current relay to function, opening the circuit and preventing discharge by breaking the closing coil circuit of the magnet contactor. Upon the return of power the magnet contactor will reconnect the battery, its closing coil being energized through the contact of the reverse-current relay, which will be closed by its shunt coil. Upon completion of the charge, as determined by the ampere-hour meter, the circuit breaker will open the circuit, being tripped by its shunt coil, which is energized through the zero contact of the ampere-hour meter.

The circuit breaker will open also in case of any short-circuits that cause overload. When the difference between the line and battery voltages is so great that the time of charging becomes excessive, it is possible to use a two-step resistor and increase the rate during the first part of the charge, automatically reducing it at the correct point by a circuit breaker controlled through an auxiliary contact of the ampere-hour meter.

In cases where a single lead battery is to be charged from a motor-generator set the generator can be designed with a drooping characteristic such that the current will taper essentially as in the modified constant-potential system. Furthermore, the series resistance may be omitted. The disadvantage of this is that it is applicable only to a single battery of fixed capacity and of a given number of cells.

It should be borne in mind that all automatic charging outfits need some adjustment subsequent to installation, as the manufacturer seldom knows the exact voltage conditions or the loss in voltage in the connecting wires. Either resistors are provided with taps to permit slight changes or a certain degree of generator-field adjustment is possible, and a little experimenting will determine what is needed.

What is termed an "equalizing charge" must be given to a lead battery approximately once each week, whatever normal charging method is used. This consists of a prolonged overcharge, disregarding the ampere-hour meter, at a rate preferably about one-half the finishing rate, though if conditions make a reduction impossible, the finishing rate may be used, provided the cell temperature is watched and kept within the permissible limit. The object of this charge is to make up for any deficiency in normal charging caused by inaccuracies in the ampere-hour meter or by peculiarities in the individual cell and to be absolutely certain that all the cells and all the plates in each cell are fully charged.

It is advisable to use one cell of the lead battery as a "pilot cell" as a guide to the condition of the whole. Before discontinuing the equalizing charge all cells of the battery should be gassing freely and evenly and three consecutive half-hour readings should show no increase. Occasionally, at the end of an equalizing charge, a record of the specific gravity of each cell should be taken. A slightly higher final cell voltage is required for equalizing, but usually no special provision need be made, as the load is small and the natural regulation sufficient. When the straight constant-potential system is used, however, it frequently is impracticable to raise the bus voltage as much as is necessary, in which case the battery must be divided into two groups and a series resistor inserted.

It is sometimes necessary that a battery stand idle for a prolonged period. The simplest way to prevent deterioration is to give it an equalizing charge about once a month and, of course, add water occasionally. If this infrequent charging is impossible it usually is best to dismantle the battery, and instructions to suit the conditions should be obtained from the manufacturer.

Charging Requirements of Nickel-Iron Battery

The requirements for charging batteries of the nickel-iron type differ in many respects from those enumerated for the lead battery. On the whole there is much less chance of injuring the battery by improper charging, though the performance and output may be adversely affected if certain precautions are neglected. The charging rate is limited only to that which will not produce a cell temperature in excess of 115 deg. F. or cause frothing at the filler opening. The greater internal loss renders the possibility of overheating much more acute than in the case of the lead battery; therefore the temperature should be carefully watched.

Normal charging for a battery of this type is at constant current, and the value chosen by the manufacturer has been found by experience to give the best results. When that current has been adhered to, practically maximum capacity is obtained and the chance of overheating, with the battery as commonly installed in locomotives, is small. The temperature of a battery will rise during discharge. How much depends on the time of discharge. Consequently it seldom is advisable to start charging just as soon as the locomotive returns to the shed. Before current is fed to it the battery should be permitted to cool.

An ampere-hour meter is about the only convenient guide for determining the state of charge, as readings of the specific gravity of the electrolyte are of no value. The meter should be adjusted to run slow on charge so that about 25 per cent more ampere hours will be returned than were taken out. As in the lead battery, some departure from this value may be advisable.

Should the extent of the previous discharge be unknown the battery may be considered fully charged when the voltage has remained constant for 30 minutes at about 1.9 volts per cell with normal current flowing. The precautions mentioned for the lead battery with respect to ventilation of the compartment and exposed flames should be strictly followed.

The nickel-iron battery will give its best performance if charged at the normal constant-current rate. To obtain a reasonably constant current, without excessive loss, the current flow must be adjusted manually. Practically the only objection to this method, if the precautions mentioned are taken, is the attention required. The danger of overheating is not great, and overcharging is not harmful. The charging rate is satisfactorily adjusted either by varying a series resistor or the field of the charging generator, as in the case of the lead battery. The curve, Fig. 5, shows the variation in terminal voltage for constant-current charging.

Finishing Current Too Weak to Be Effectual

Though strictly constant-potential charging without series resistance does not involve as high an initial peak as in the case of the lead battery the tapering of the current to a small value at the end of charge is objectionable. It has been found that the portion of the charge at less than the normal value of current is not sufficiently effective in performing the necessary electro-chemical action to charge the battery completely. The effects are shown by sluggish action and a gradual reduction in the effective discharge voltage. The battery is in no wise harmed by this treatment and may be restored to a healthy condition by means of overcharging and several cycles of normal charge and discharge. The employment of this method is practically precluded by the inefficiency and poor performance of a battery regularly thus charged.

Automatic charging, of course, is very desirable and it is most commonly obtained by practically the same method as that termed "modified constant-potential" in the case of the lead battery. The scheme of connections shown in Fig. 3 applies equally here. The use of a fixed resistor will result, of course, in a tapering charging current and loss of capacity similar to that experienced when true constant-potential charging is employed, but the effect becomes less as the variation in the current from start to finish decreases.

The charging current should average practically normal and the variation will be less as the series resistance and bus voltage per cell are increased. The energy loss is quite appreciable when the resistor is of a value to give satisfactory results. Experience has shown that a battery can be kept up to essentially full capacity if the charging current is not permitted to fall below approximately 80 per cent of normal at the end of charge. The extremes allowable with this method are therefore from 20 per cent above to 20 per cent below the normal rate. This requirement necessitates a line voltage equivalent to about 2.25 volts per cell. The approximate current and cell voltage curves for charging through series resistance with a line voltage of 2.25 volts per cell are shown in Fig. 4. Increasing the line voltage and series resistance is favorable, of course, to the battery performance, but results in greater losses.

This type of battery can also be successfully charged automatically without series resistance from a generator designed with a drooping characteristic produced by the combination of differential series and shunt-field windings. The variation in the charging current from start to finish may be even less than the maximum recommended in the preceding paragraph. Only a single battery of fixed capacity and number of cells can be charged from such a generator, and this is frequently undesirable from the standpoint of both convenience and cost.

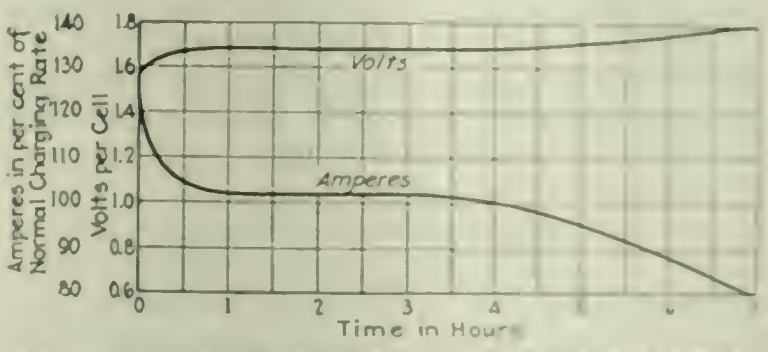

FIG. 4—CHARGING CURVES, NICKEL-IRON BATTERY
Approximate curves with a fixed series resistance and a line potential of 2.25 volts per cell

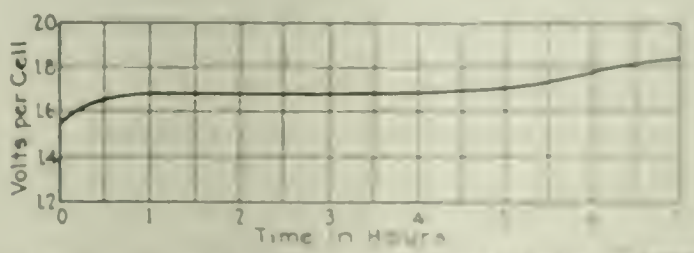

FIG. 5—CHARGING CURVE OF NICKEL-IRON BATTERY
This also is a curve which would be modified with a different condition of battery, another temperature and a changed cell structure.

The nickel-iron battery may be taken out of service and permitted to stand in any state of charge or discharge without any resulting injury. It is necessary to keep the plates covered to the proper height with electrolyte, and therefore distilled water to replace evaporation must be added occasionally. The battery should be stored in a dry place and when put in service again given a long overcharge after careful inspection of the cells.

An equalizing charge such as that necessary for the lead battery, of course, is never given, but an overcharge is often desirable, especially if in normal service the battery is seldom completely discharged. The overcharge should be continued approximately 50 per cent longer than the time required for a complete normal charge and will be most effective for good if the battery is first completely discharged, even to zero voltage.

Stone Dust, Water and Steam as Means of Protection Against Mine Explosions

A DISCUSSION by a representative body of mine inspectors at the annual meeting of the Mine Inspectors' Institute of America this year gave a well-balanced review of the methods to combat the coal-dust hazard now in effect in the United States. There was no consensus of opinion. Most of the men, who spoke from the fullness of their experience with one system or another, agreed that no method was anywhere near 100 per cent perfect, but that as a damper on explosions any and all have a marked effect and each has its place.

Men from both West Virginia and Alabama were strongly in favor of a lavish use of water throughout coal mines from mine opening to face. C. H. Nesbit, of Alabama, past president of the Institute, said that the common method in his state was to wet down mines regularly with water at 80 lb. pressure. Sluicing off roofs, timbers, walls and floors, he said, was a most effective way to remove dust, which was the origin of explosions, and that the use of water under pressure undoubtedly prevented much trouble in the mines where the practice is maintained.

V. E. Sullivan, of West Virginia, said that in his state it is standard practice to wash down the main ways thoroughly and to introduce humidified air into the air courses. Results, he said, have been uniformly good. J. H. Haskins, of Illinois, remarked that if any such volume of water were to be turned loose in the mines in the No. 6 seam in Illinois those mines simply would not be workable. There is too much water there already. He contended that the wetting down plan is not everywhere feasible.

Colorado is a state, said James Dalrymple, chief inspector of that commonwealth, where every imaginable mining problem is encountered and where conditions vary from one extreme to the other, sometimes within a small district. He said the hope is not so much to prevent explosions as it is to prevent coal dust from taking part in them. Naturally complete prevention would be ideal, but as nobody knows how to achieve that Utopian goal, the next best thing is to render dust as nearly innocuous as possible and then strive to reduce the hazards of the face—the spot which Mr. Dalrymple believes the source of most "blows."

Moist Mine, Not Merely Moist Air, Is Wanted

In his state water is used plentifully in certain mines and an effort is made in most of them to humidify the air to a point somewhere above 90 per cent by introducing exhaust steam. But even this is not a reliable protection, he said. A 100-per cent humidification by steam wouldn't prevent a blast. Hence water is used where practicable. Water conditions are so variable, he said, that he knows of regions where a mine that must pump for dear life to keep its workings dry enough to operate is within 15 miles of a mine so dry that wells driven 2,500 ft. get not a drop, and water must be hauled in in tank cars at great expense.

It is well known that steam, as a humidifier, is damaging to mine timbers, causing much trouble in certain operations. Mr. Dalrymple said that he has observed that the damage is much less where humidification goes on 24 hours a day than where it is spasmodic. The continual change from wet to dry is far more damaging than constant moisture.

Humidification has no effect whatever as a deterrent after an explosion once has started, according to J. W. Paul, mining engineer at the Bureau of Mines experiment station in Pittsburgh, Pa. He said experiments have clearly proved that 100 per cent humidification is no better in the face of a blast than 65 per cent. Humidification is of real value, however, in a mine, he said, because it offsets evaporation and so keeps the coal dust wet.

Mr. Paul strongly advocated the use of rock dust to stop the force and spread of explosions. He said that from 5 to 8 lb. of pulverized rock is enough to neutralize all the coal dust produced at a working face in each shift and suggested that it would be a good plan to supply each miner with a bag each day containing that quantity. It would take him just about half a minute to toss the rock dust around and coat the ribs and roof with it. By this means not only would safety be increased but a "concreting" effect would be produced, thus greatly improving the illumination of the working place.

"But," added Mr. Paul, "I don't know whether the men would be willing to spend half a minute doing it."

"I know exactly what they'd say in Illinois," contributed Thomas Back, of Peoria, Ill. "They'd say 'Who's gonna pay us for all this extra work?'"

Others surmised that the miners would use the rock dust to tamp shots. If they did, somebody suggested, why wouldn't that produce the same results? The dust would be thoroughly distributed by the shots, thus producing the desired effect. The answer was that if the shot was good, distribution would be poor.

Salt as a Medium for Gathering Moisture

From that point the discussion shifted to the use of salt as a humidifier when used as stemming by shotfirers. James Sherwood, of Kansas, said that at one time he had encouraged the use of it in his region, for he found that great waste piles at salt mines could be obtained at $1 a ton. Unfortunately as soon as the demand for it was noticed by the salt plants the price went out of sight, and it became too expensive for coal mining.

An expert opinion on the use of salt was asked of S. P. Howell, explosives engineer at the Bureau of Mines experiment station in Pittsburgh. Mr. Howell said the salt would stay in the borehole providing the shot performed as it should, thus rendering the salt worthless for the purpose intended. Only windy shots would distribute it around the room. He said, further, that if the salt were tamped in too close to the explosive it would become, at the moment of firing, an ingredient, thus modifying the strength and character of the explosive to such an extent that the miner would never be able to tell how large a charge of explosive he ought to use to bring down the coal.

The success of the Old Ben Coal Corporation in the use of shale dust as a check against explosions was mentioned by W. L. Morgan, who explained how the dust is suspended along roofs of entries in delicately balanced troughs. The air blast traveling ahead of an explosion dumps the dust into the atmosphere, damping out the force and flame of the "blow" with remarkable results. Experience has shown the safety engineer of the Old Ben company that a mine cleaned and watered by the best-known methods is little, if any, safer than one knee-deep in coal dust. Therefore a tremendous effort has been made for years to find ways of checking explosions after they start. The shale dust is the most effective means thus far developed.

Washing Coal in Large Pipe by an Upward Current of Water

SPEED in washing, the use of the pressure of the water delivered to the washer to accomplish the desired results, the expenditure of a minimum of power and a saving in space are all advantages that can be claimed for the Draper coal washer, manufactured by the Rhondda Engineering & Mining Co., Ltd., of Bridgend, Glamorganshire, South Wales.

The illustration, Fig. 1, shows a washer capable of cleaning 10 tons of coal per hour. It occupies a floor space of only 5 ft. 3 in. x 2 ft., the height being 8 ft. 9 in. If a machine of this kind will do the work claimed for it, it will be unnecessary to build the big structures that have been erected in the past for the washing of coal. A washery then will be a far less conspicuous building.

The unwashed coal is delivered, as shown in Fig. 2, into a small hopper at the top of the washer unit. It falls into another hopper and is met by a current of water striving to escape. This water has entered by a water inlet below the second hopper. The coal is not heavy enough to resist the current, and it is swept into a chute with and by the escaping water. The sulphur and slate, however, can make their way despite the outrush of water and they fall into an 11-in. cast-iron pipe below the real washing section. It drops onto a

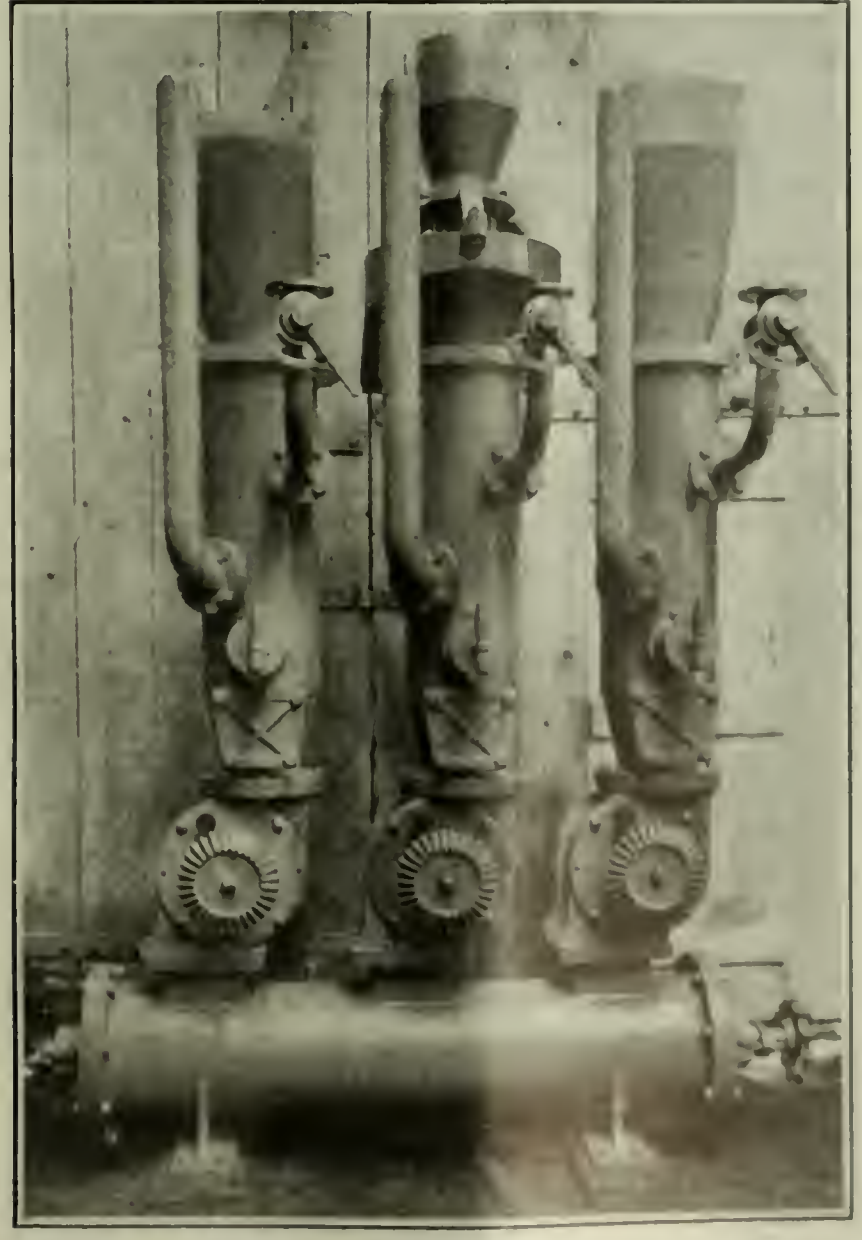

FIG. 1—EXTERIOR VIEW OF THE DRAPER WASHER

Water comes in by the index valve at the small pipes to the right of the larger ones. The coal enters at the top of the large pipes. The coal is held up by the upflowing water and escapes with it by a chute in the rear. Valves [illegible] Just above the drum progressively empty out the waste material as fast as it collects.

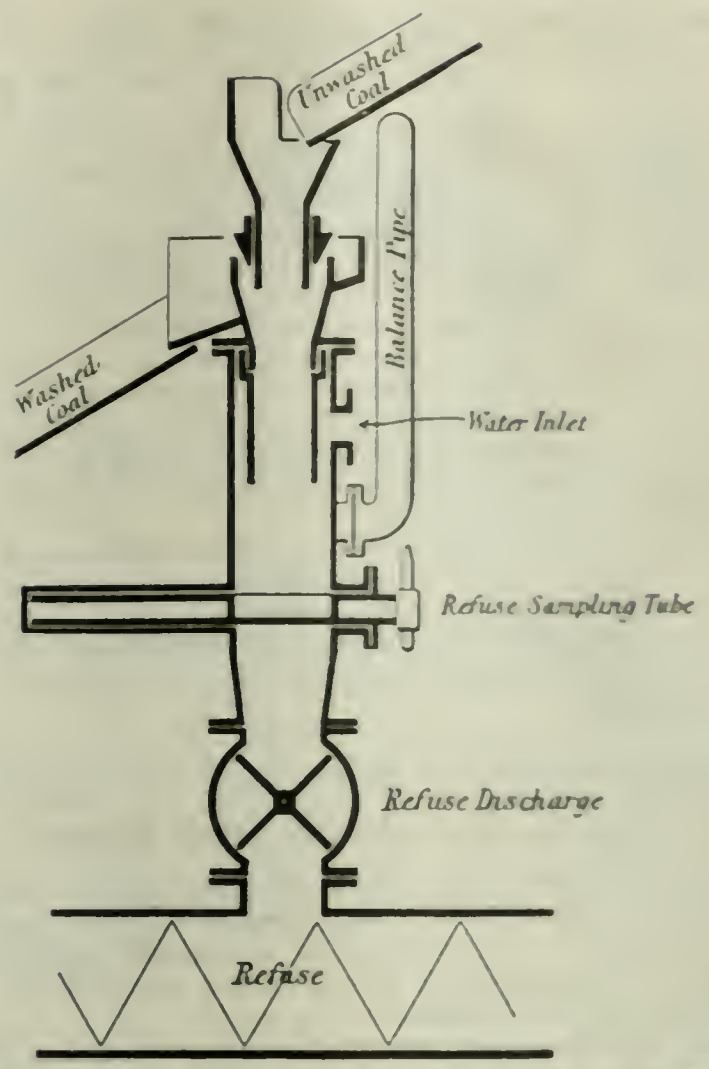

FIG. 2—WASHER ON THE PRINCIPLE OF THE RIFFLE

The riffle washer operates essentially on the principle that water on a grade on meeting a riffle is lifted up by it and that if light and heavy material are being carried along with the water the light will be carried with it and the heavy will stay behind. The trouble is that the riffles soon fill up, and so several are used to give capacity. Here the equivalent to the riffle is deep and also self-cleaning, so the one "riffle" will do the work.

valve which is built like one of the revolving doors which are installed at large buildings to keep out the cold air and yet admit visitors. This four-winged butterfly valve slowly revolves and removes all the refuse, with only a minimum of water, dropping it into a refuse drum.

In order to sample the refuse a hole has been provided through the walls of the 11-in. tube previously referred to. In this a sampling tube is placed, held in position by a short boxing on one end and a longer one on the other. The sampling tube is so made as to carry a box which normally is kept with its opening downward. When, however, a sample of the refuse is desired, the tube is revolved and the receptacle filled with the reject. The turning of the sampling tube unlocks it, and it can then be drawn out and the sample dumped into a tray for investigation.

Washer Will Not Break or Abrade Coal

It is claimed that the Draper washer will separate effectively shale from coal of all sizes from the finest dust up to 4-in. cubes. The washer is controlled by the index handle on the water inlet, which regulates the volume of the washing water and hence its velocity. The action of the washer is quite easy and consequently the coal is not broken or abraded by the treatment as it is apt to be in jig washing.

It is said that the water and power used is halved by this method of washing. Several of these washers are at work not only in Great Britain but in Spain, China and France, cleaning not only raw coal but ashes from boiler plants, coke, slack and the reject from other washeries.

Class 1 Roads Used 7,256,000 Tons of Coal In August; Cost, $4.87 Per Ton

During August, 1922, Class 1 railroads consumed 7,256,000 net tons of coal, as charged to account 734, compared with 6,246,000 tons in July and 7,279,000 tons in August, 1921, according to figures published by the Bureau of Statistics, Interstate Commerce Commission, covering 165 reports representing 172 steam roads. Coal consumption for the first eight months of the year totaled 58,925,000 tons as compared with 59,788,000 tons during the same period of 1921.

The delivered cost of the coal during August was $4.87 per ton, as compared with $4.86 in the corresponding month of last year. For the eight months ended Aug. 31, 1922, however, the cost per ton was only $3.82; in the same period of last year it was $4.31.

Fuel-oil consumption by the railroads continued to gain during August, when 126,957,000 gal. was used, as compared with 114,820,000 gal. in August, 1921. During the first eight months of this year 958,879,000 gal. was consumed, approximately 32,000,000 gal. in excess of last year's figures.

Utilities Consume More Coal in September Than in Any Month Since January

Electric public utility plants consumed 2,907,672 net tons of coal during September, according to a recent report of the Geological Survey. This is the largest tonnage consumed during any month since January and compares with 2,815,685 tons in August.

The average daily production of electricity by public-utility power plants in September again broke all records, this being the third time in four months that records of output have been surpassed. The daily production of electricity in September was 135,200,000 kw.-hr., 3 per cent greater than the August record and nearly 6 per cent greater than the June record.

The daily consumption of both oil and gas in the production of electric power also broke all records in August and September, the consumption of these two fuels in September being especially large in comparison with previous months of this year and of the other years of record, indicating an abnormal use of these fuels which has probably been brought about by the difficulty in obtaining coal.

More Mine Fatalities in September but Fewer In Ratio to Output Than in August

Accidents at coal mines in September resulted in the death of 153 men, according to reports from state mine inspectors to the United States Bureau of Mines. Nineteen employees were killed at anthracite mines in Pennsylvania and 134 were killed at bituminous coal mines throughout the country. In September last year 167 men were killed, of whom 45 were killed at anthracite mines and 122 at bituminous mines. The production of coal was 46,196,000 tons in September, 1922, and 43,329,000 in the corresponding month last year; hence, for each million tons of coal mined the fatality rate for September, 1922, is 3.31 as compared with 3.85 a year ago. During August, last, there were 98 fatalities, or 3.80 per million tons of production.

The average fatality rate for September during the nine-year period 1913-1921 is 3.65 per million tons and the average number of fatalities is 186. Thus the record for September, 1922, shows a reduction both in the actual number of lives lost and the fatality rate per million tons, when compared with September's record a year ago and the general average for the same month since 1913.

On Sept. 23 five men, shaft sinkers, were killed by a falling cage while cleaning out a sump at Raleigh-Wyoming mine No. 2, at Glen Rogers, W. Va.

During the nine-month period January to September of the current year, 1,186 men have been killed by accidents at coal mines, as compared with 1,485 killed in the corresponding months last year. The fatality rate per million tons is 3.98 this year as against 4.07 for the first nine months of 1921. Because of the general strike recently closed, the output of coal in 1922 has reached only 298,000,000 tons, while during the nine-month period last year the production was 365,000,000 tons.

Problems of Operating Men

Edited by James T. Beard

Conferences on Mine Safety Problems

Bureau of Mines Recommends the Certification of All Mine Officials Having Responsible Charge of Mining Operations—Experience Generally Gained Through Some One's Carelessness or Ignorance

AFTER reading a recent circular letter, issued by the Colorado Fuel and Iron Co. and posted on their bulletin boards, I am deeply impressed with the recommendations, which appear to come from the Bureau of Mines.

The bureau is composed of expert mining men and their recommendations should be given careful consideration by every man engaged in the work of mining coal.

The circular bears the caption:

"From U. S. Bureau of Mines,
Conference on Mine-Safety
Problems"

It draws attention forcibly to many of the points that have been widely discussed by readers of *Coal Age*. It is a satisfaction to know that these receive the endorsement of the Bureau of Mines. The safety of life and property, in the mining of coal, cannot be assured, unless the men in charge are thoroughly familiar with the dangers that surround the undertaking and adopt means of preventing accidents.

Certification of Mine Officials Recommended

Chief among the recommendations presented in the letter is the following: "All persons in responsible charge of the direct operation of coal mines, including superintendents, foremen, firebosses, and shotfirers, should be required to have certificates of competency, issued by the state and showing that the applicant has passed an examination clearly establishing his knowledge of what constitutes up-to-date safe practices in the branch or branches of mine operations under his jurisdiction.

"All such certificates should be revocable by the state, for cause, and should expire after five years and be renewed only on taking another examination. The latter requirement would compel all operating mining men to keep conversant with progressive safety practices."

In making this recommendation, the conferees have advanced one step in the certification of mine officials. I note that they recommend that mine superintendents be required to pass an examination before a state board of examiners and hold a certificate of competency issued by the board.

In discussing this question, I have heretofore contended that it was not necessary for a superintendent to be certified, provided the mine foreman holds a certificate. However, the Bureau of Mines engineers are in a position to know whereof they speak, and, as I have said before, if the certifying of superintendents will make our mines safer I am for it heart and soul.

Perhaps I have not given the outside operations sufficient thought. Undoubtedly, there is danger on the surface, as well as underground; and, viewing the situation from a broad angle, I frankly confess that the certification of mine superintendents would not be amiss.

Letter Recommends Limiting the Life of Certificates

Again, this circular letter recommends limiting the life of certificates to five years, after which they must be renewed through the taking of another examination. This suggestion has my heartiest approval. Few will deny that a large number of our certified men neglect to keep posted in regard to the requirements of the mining laws of their states; and technical questions, relating to the various branches of mining, receive little attention after a man has once been granted his papers and has started performing his regular duties.

If I am not mistaken, the purpose of these recommendations is to keep all mining officials, who are responsible for the safe operation of mines, thoroughly familiar with everything that pertains to safe up-to-date practices, regarding the ventilation of mines, danger of dust and explosives, and the use of electricity as employed in the various operations in and about mines.

Miners Should Read Mine Laws

Not long ago, I had the pleasure of listening to a paper on mine accidents. When suggestions were asked regarding their prevention, someone stated that every mine worker should be required to secure a copy of the state mining laws and read them. A few days later, one of the men said to me, "Why did Mr. —— suggest the reading of the mining laws by all mine workers?"

What prompted the question was probably the fact that the Colorado mining laws place the responsibility for the safe operation of mines directly on the shoulders of the mine owners, board of examiners, state and deputy inspectors, mine foremen and assistant foremen, firebosses and shotfirers. Of the 178 sections of our law, I believe only three relate to the responsibility of the worker.

The letter further recommends that every mine should be made the subject of special study, regarding its gas and dust condition. I believe this is already being done by our state and district inspectors. If the suggestion has reference, however, to the Bureau of Mines making such a special study of individual mines, there is little doubt but that they would always be welcomed and every assistance accorded them, in the mines of Colorado.

It was only a few days ago that I overheard a remark made by a mine official who, speaking of a recent mine disaster, said, "we always lock the stable door after the horse is stolen." It would seem true that our richest experience is only gained through disasters caused by the carelessness or ignorance of others. Let us, as mine officials, take to heart the lessons taught by these experiences and profit by them.

Walsenburg, Colo.

Locating the Coal Beyond a Fault

Indications left along the line of fault showing upthrow or downthrow—Observations appear to upset generally accepted theory—Discussion asked.

WHILE making an inspection of a coal mine, a short time ago, I picked up an old file of Coal Age, in the superintendent's office. It was not long before my eyes rested on an article that interested me. It treated on the method of determining whether a fault of displacement, when found in a mine, was an upthrow or a downthrow.

The fact has long been generally accepted that Nature, in all her constructive phases, has left sure-or-indistinct evidences that enable us, at least, invite a close study for the purpose of determining the conditions under which certain observed geological changes have taken place.

Faults of Displacement Show the Direction of Movement

In respect to a fault of displacement, the belief is well grounded that she has left indications that point to the direction in which the movement or displacement of the strata took place. As the name signifies, a "fault of displacement"

or "dislocation," in a coal seam or other stratum, presents the appearance of the seam having been disrupted along a distinct line that makes a considerable angle with the plane of stratification.

It is plainly evident that the disruptive force has operated across the strata, causing them to break and slide up or down along the line of fracture. For the purpose in hand, we are not interested in the origin or nature of this force, but are concerned only in ascertaining the direction in which the slip of the strata took place.

Problem Presented on Meeting a Fault of Dislocation

The question for the engineer to determine, on meeting such a fault in the coal seam, is: Will the continuation of the seam be found above or below the seam being worked? In order to answer this question, he examines closely the indications that are to be found in the seam and the adjoining strata, hoping that these will point the way.

Referring to Fig. 1, I have illustrated a fault of displacement. Assuming

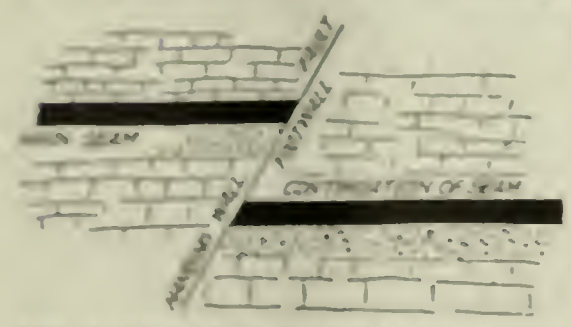

FIG. 1—SHOWING MANNER IN WHICH FAULTING TAKES PLACE

that the portion of the seam shown as lying on the left of the line of fault, marked "main seam," is the one that is being worked, this fault is evidently a downthrow, since the continuation of the seam shown on the right of the fault line, lies below the portion that is working.

Generally Assumed Condition Not Found in Observed Faults

In Fig. 2 is shown the condition that is generally assumed to result from the slip of the strata on each other when the fault occurred. As indicated in the figure, where the condition is purposely exaggerated, the ends of the strata forming the faces are bent downward and upward, respectively, as they were torn apart when the strata slipped.

In other words, the deflection of the cleavage planes are in the opposite direction from that in which the disrupting force acted on the two respective portions of the seam, throwing the one downward and the other upward, relatively. Thus, the deflection of the cleavages, in either portion of the seam, has been generally assumed to point in the direction in which the remaining portion may be found.

Having had occasion, as a coal mine, to cut a number of faults of displacement at different times, I have always made it a rule to closely observe the conditions existing on both sides of the fault line. In every instance, strange as it may seem, I have found the deflection of the cleavages, in the seam, close to the fault, pointing upward when the displacement was downward, and pointing downward when the displacement was upward.

Proposed Theory to Explain This Seeming Misconception

In my feeble attempt to explain this seeming contradiction of the generally accepted theory regarding faults of

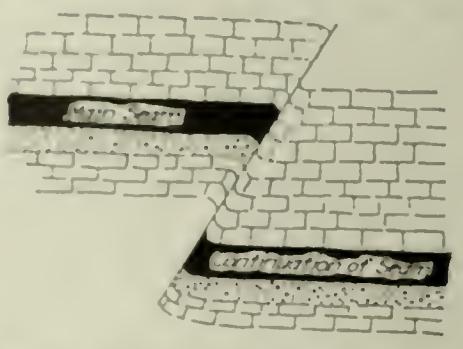

FIG. 2—SHOWING BENDING OF STRATA AS GENERALLY ASSUMED

displacement, I have assumed that, following the action of a disruptive force producing displacement in the strata, there is a tendency, on the part of the disrupted portions, to react or return to their former positions.

This is only a theory of mine that, if correct, would explain my finding of the cleavages, along the line of fault, deflected in the opposite direction from that in which the displacement has taken place. Allow me to present this theory of the action of faults of displacement to the readers of *Coal Age*, with the request that, before pronouncing it as "visionary," they will carefully inspect faults of dislocation that are available to them and give us the benefit of their observations.

Washington, D.C. I. C. Parfitt.

Economy in Use of Mine Timber

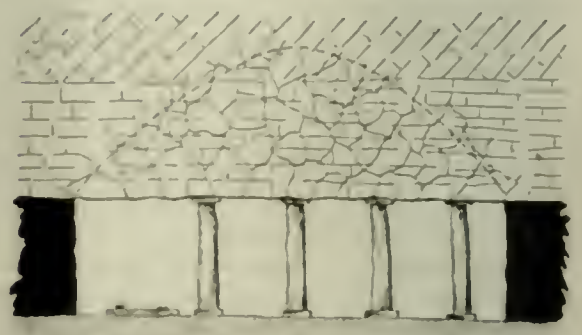
Much timber wasted in drawing pillars —Purpose of setting post timber— Conditions affecting the life and use of timber in mines—Greater economy required in its use.

LEADING the excellent article of William Allan, entitled "Where Coal-Mining Practice Could Be Materially Improved," *Coal Age*, Oct. 26, p. 675, one is not a little surprised to observe that he fails to mention the need of more economy in the use of mine timber.

Experience has taught me that there is a greater waste of timber, in the work of drawing back pillars than there is in the mining of solid coal. I have observed that, in nine cases out of ten, the miner is largely to blame for this waste. The average miner either gives little thought to the matter, or is guilty of lack of judgment in setting his posts, in robbing pillars.

Frankly, it is only right that miners should be provided with an ample supply of timber to make themselves safe. At the same time, it is imperative that he should use judgment in standing his posts. This is particularly true in the work of drawing back pillars, when no standard rule can be given regulating the setting of posts.

The practical miner realizes, of course, that posts are never set to support the weight of cover above them, but to safeguard the miner by warning him of an approaching squeeze. This is not saying that squeezes are not continually taking place where pillars are being drawn; but that is no sign of immediate danger. The observed condition of the posts set, however, is an index of the amount of pressure on the timber and the rate at which it is increasing, which is what the miner must know if he is to avoid danger.



Economy of Timber Requires Close Study of Conditions

Many conditions in the mine affect the life of timbers set for the support of the roof. A study of these conditions, in their relation to timbering, is of the utmost importance in determining the proper use of mine timber.

When mining under a strong roof that is hard to break little timber is required in the first working. Under these conditions, the quality of the timber employed is not of the same importance as where the roof is more treacherous. It don't matter whether the timber is hard, soft, good or bad, when such a roof does begin to break all timbers are alike ineffective to resist the action.

Working Under Bad Roof Demands Strong Timbers

On the other hand, where the roof is bad and breaks readily the chances are that the chambers will have to be propped or retimbered, before the pillars can be taken out with safety. Under these conditions, the quality of the timber employed is of the greatest im-

OVERARCHING OF ROOF THROWS THE WEIGHT ON PILLARS

portance. The posts set must be strong enough to carry the loose material above the opening, while the weight of the overburden arches and rests on the pillars.

Statistics show that more accidents occur where the roof in a mine is good. This is probably owing to the fact that miners fail to keep as close a watch, or take the same precautions that they would when working under a roof known to be bad. The fact goes to show the need of taking every precaution, under all conditions.

Much of the timber used in our mines, today, could be saved if the coal was to

be worked out on the retreating system of mining. This system is too well known to need further explanation than to say that, in the work of development, the headings or entries are driven in solid coal and require far less timber to maintain them than when mining on the advancing plan.

Again, when retreating less timber is required in the chambers, under like conditions of roof and floor. The first chambers are opened at the inby end of the heading, or at the boundary of the property. As soon as these chambers reach the limit the pillars between them are drawn back.

Effect of Change of Seasons on Life of Timber

The life of mine timber is an important factor in economy. In this respect, much depends on atmospheric conditions and the physical surroundings in the strata. At one time, I worked in a mine where the ventilation was subject to change with the changes in the seasons. The intake airway in the winter became the return airway in summer.

In this mine, also, such were the roof conditions that the roadways required to be timbered so closely that one set of timbers could not be put in place, until the old set had been taken out to make room for the new timbers. Owing chiefly to changes in atmospheric conditions, however, the timbers on the main roads, in this mine, had to be replaced more frequently than on any other passageway.

Notwithstanding the increasing use of I-beams in place of timber in mines, it is very essential that more attention should be given to the need of economy in the use of mine timber. Each year, the supply of a good quality of timber for mining, grows less and less.

Cutting Timber to Required Length

Not long ago, a number of writers drew attention, in *Coal Age*, to the need of cutting timbers to the desired length, on the surface, before they are sent into the mine and delivered at the working faces. To my mind, this is an important suggestion and one that is worthy of careful consideration by all mine operators.

Miners have come to me asking for props, but were unable to tell what length they required. Frequently, they would specify a length that was a foot or two too long. In such cases, what they did not use for cap-pieces would be thrown into the gob and lost. A careful estimate of the waste, from this source alone, each year, is astonishing. Occasionally, it will happen that a miner will bury an extra heavy prop in the gob, rather than exert himself to stand it in place.

Allow me to suggest, in closing, that it would be well to frame a set of rules regarding timbering and post these in a conspicuous place at the mine. If this was done and the rule strictly enforced, it would go a long ways toward reducing the present unwarranted waste in mine timber.

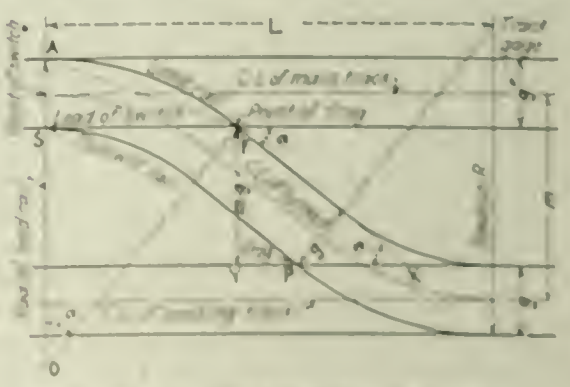
Plains, Pa. Richard Bowen

Inquiries Of General Interest

Calculating Dimensions of Turnout or Crossover Switch

Need of Careful Calculation of All Dimensions of Switches—Track Gage and Size or Number of Frog to Be Used First Determined—Other Dimensions Calculated from These Data

SOME of the switches laid for turnouts in our mines have always given trouble; not so much by reason of derailment, for this has seldom happened in switching cars at turnouts. The chief trouble seems to be caused by lack of alignment and, as a result, the rails become worn and tracks need frequent repairs. After many trials, I have concluded that a track switch must be carefully calculated and laid out by exact dimensions.



Kindly explain, through the columns of *Coal Age*, the essential requirements for making these calculations; and show the derivation of the formulas used. My purpose in asking this is to develop a standard switch and form of turnout, for use in our mine, where the track gage is 42 in. (3½ ft.). We are using No.-3 frogs in these switches and 30 lb. rails on the main road.

Trackman.

————, Ill.

From the information given by this correspondent, we judge that his conclusion is correct and that the fault lies in the dimensions of the switch not conforming to other fixed data, such as track gage, number of frog employed and distance between track centers.

In designing a crossover switch similar to that shown in the accompanying

PLAN OF CROSSOVER SWITCH

diagram, assuming a given track gage (g) and frog number (n), the first step is to calculate the radius (R) of the lead rail, the length of its chord (c) and the exact position of the frog measured from the point of switch to the point of frog on the straight rail of the main track. This distance (d) is called the lead of the switch.

But, the angle AOF subtending the lead rail is, evidently, equal to the frog angle, and the chord ($AF = c$) corresponds to the spread of the frog for a distance $OF = R$. Then, since the frog number (n) is the ratio of one arm of the frog to its spread, we have $R = nc$.

Again, the angle AFS being half the frog angle and AS the track gage (g), it is clear that $2g$ is the spread of frog for a distance $AF = c$; and $c = 2gn$; which gives $R = nc = 2gn^2$.

Applying this formula to find the radius of lead rail, for a track gage $g = 3\frac{1}{2}$ ft., and using a No. 3 frog, we have

$$R = 2gn^2 = 2 \times 3\tfrac{1}{2} \times 3^2 = 63 \text{ ft.}$$

For the length of chord subtending the lead rail ($AF = c$), we have

$$c = 2gn = 2 \times 3\tfrac{1}{2} \times 3 = 21 \text{ ft.}$$

Approximately, the middle ordinate (o) of the lead rail, in inches, is found by dividing three times the square of the chord, in feet, by twice the radius, in feet, which gives, in this case,

$$o = \frac{3c^2}{2R} = \frac{3 \times 21^2}{2 \times 63} = 10\tfrac{1}{2} \text{ in.}$$

For the lead of switch ($SF = d$)

$$d = \sqrt{c^2 - g^2} = \sqrt{21^2 - 3\tfrac{1}{2}^2} = 20.7 \text{ ft.}$$

Total Length of Crossover

The next step is to find the total length (L) of the crossover, from switch point to switch point, as measured on the straight rails of either track. Calling the distance between track centers m, the distance between the gage lines of the inner rails of the two tracks is $m - g$. Then, calling the frog angle a, we have

$$YP = YX - PX = \frac{m - g}{\tan a} - \frac{g}{\sin a}$$

To calculate the frog angle, assume the spread as unity, which makes the length of each arm n, and we have, for a No.-3 frog,

$$\sin \tfrac{1}{2}a = \frac{\frac{1}{2}}{n} = \frac{1}{2n} = \frac{1}{2 \times 3} = \frac{1}{6} = 0.1667$$

or $\frac{1}{2}a = 9^\circ 36'$ nearly; and $a =$ say $19^\circ 11'$; $\tan a = 0.346$; and $\sin a = 0.3287$. Substituting these values in the formula previously given and assuming a distance between track centers $m = 8$ ft.

$$YP = \frac{8 - 3.5}{0.346} - \frac{3.5}{0.3287} = 2.58 \text{ ft.}$$

Since the same dimensions answer for both ends of the crossover, using the same frog number in each track, the

total length of the crossover or distance from point of switch to point of switch, as measured on the straight rail of either track, is

$$L = 2d + Yl' = 2 \times 20.7 + 2.28 = 43.68 \text{ ft.}$$

At times it may be desired to use a fixed lead and find the frog number, or angle of frog, that will suit a given track gage. Then, since $c' = g' + d'$; and $c = 2gn$, we have

$$n = \frac{\sqrt{g' + d'}}{2g}$$

These are the essential switch formulas and by combining them it is possible to calculate the dimensions required to suit various conditions.

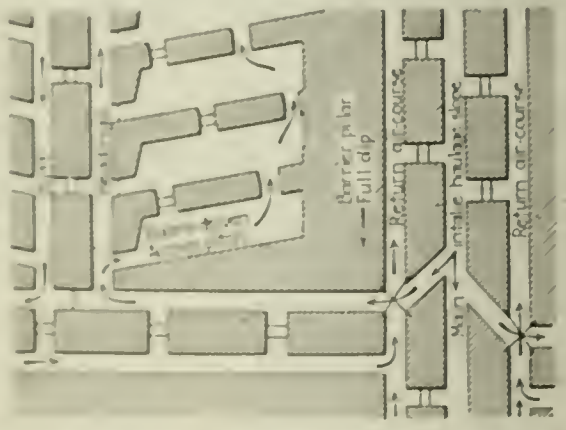
Examination Questions Answered

Mine Managers' Examination, Nova Scotia, 1922

(Selected Questions)

QUESTION—*How do you account for explosions frequently causing more damage in main intake roads than in returns and faces?*

ANSWER—A mine explosion, whether of dust or gas invariably produces the greater manifestation of violence in the direction of the intake air. The reason for this is that the combustion of the dust or gas requires air. On the return side of the explosion, the combustion is retarded, or may cease entirely for lack of air, the flame being extinguished in the products of the combustion, which always lack available oxygen. Because of the greater violence, due to the greater activity in the direction of the fresh air on the intake side, the damage is always greater in that direction than on the return side of the explosive wave.



QUESTION—*Name as many as you can of the possible causes of underground explosions?*

ANSWER—An underground explosion results from the ignition of accumulated gas, or of a dust-laden atmosphere. The causes of the ignition are numerous and may be stated as: exposure to a naked lamp, or the flame of a firemans shot in blasting; or as the result of the sparking of electric wires; the blowing out of a fuse; or a spark struck by a miner's pick coming in contact with a sulphur ball or hard rock. There are instances recorded where explosions have resulted from gas being ignited by sparks due to certain flinty rocks falling from the roof. The ignition of gas at the open end of a miner's safety or falling rock is conceivable.

Frequent causes of the ignition of gas, or a dust-laden atmosphere, are defective safety lamps; or the improper use of a safety lamp, in the hands of an inexperienced person. A lamp that is improperly assembled, or the gauze of which is otherwise defective, or in which is seen flame through the gauze, or in the top gas or dust-chamber, any surrounding the lamp. When a lamp is exposed for too long a time to an explosive atmosphere the gauze becomes heated and the lamp is then unsafe and liable to cause an explosion if gas or dust is present in the air current. If a lamp is carried against a strong air current, or allowed to fall, or exposed to a sudden concussion of the air, it is liable to pass flame and ignite any surrounding gas or dust-laden air.

QUESTION—*Show, by a sketch, how you would arrange for the ventilation of a section of a gaseous mine pitching 35 deg., indicating by arrows the direction of the ventilating current in the airways and along the working faces.*

ANSWER—In the accompanying figure, is shown a section of a gaseous mine opened by driving the main slope headings three abreast, on the full dip of the seam. Cross-headings are then turned to the right and left of these slope headings and driven on the strike of the seam. Starting at a distance of 200 ft. from the main return air-course, butt headings are turned off the cross-entries and driven directly up the pitch, in pairs, leaving 100 yd. of solid coal between each pair of butts. As shown in the figure, rooms are driven to the right and left of each pair of butt headings, at a slight angle across the pitch, so as to assist the movement of the loaded cars on the rooms. The arrows indicate the direction of the currents.

QUESTION—*If you had a double-acting steam pump running at a piston speed of 90 ft. per min., the diameter of the plunger being 10 in., how much water per hour would it discharge; and what would be the size of the suction and discharge pipes to allow this pump to work at its best, assuming an efficiency of 85 per cent for the water-end of the pump and 231 cu.in. to the gallon?*

ANSWER—The sectional area of the plunger of this pump is $0.7854 \times 10^2 = 78.54$ sq.in. The plunger displacement, at a speed of 90 ft. per min. is $(90 \times 12 \times 78.54) \div 231 = 367.2$ gal. per min. The discharge of this pump, assuming an efficiency of 85 per cent for the water-end, is $0.85 \times 60 \times 367.2 = 18{,}727$ gal. per hr.

The diameter of the suction pipe, for this pump is $d = 0.35\sqrt{G} = 0.35\sqrt{0.85 \times 367} = 6.18$, say 6 in.

The diameter of the discharge pipe of the pump is $d = 0.25\sqrt{G} = 0.25\sqrt{0.85 \times 367} = 4.42$, say 4½ in.

QUESTION—*What would be the safe working load for a steel hoisting rope ¾ in. in diameter?*

ANSWER—The breaking strain of a 6-strand, 19-wire, cast-steel, hoisting rope, 1 in. in diameter, is 34 tons. Then, since the strength of ropes of the same kind varies with the square of the diameter of the rope, we have for the breaking strain of a ¾-in. hoisting rope, $34(\frac{3}{4})^2 = 26+$ tons. The safe working load of this rope will depend much on the depth of the shaft in which it is used. For depths not exceeding 100 yd., a factor of safety of 5 can be used, making the safe working load, in that case, $26 \div 5 = 5.2$ tons. For greater depths, a larger factor of safety must be employed, say 8 or 10, for depths of 200 and 300 yd., respectively.

QUESTION—*A pair of winding engines with cylinders 30 in. in diameter, 5-ft. stroke, running at 40 r.p.m., steam pressure 40 lb. per sq. in., what would be the approximate horsepower?*

ANSWER—The sectional area of one cylinder, in this case, is $0.7854 \times 30^2 = 706.86$ sq.in. The total pressure on one cylinder is, therefore, $40 \times 706.86 = 28{,}274$ lb. For a 5-ft. stroke and a speed of 40 r.p.m., the piston speed is $2 \times 5 \times 40 = 400$ ft. per min. The power of a single cylinder, in this case, assuming an efficiency of 85 per cent is $0.85(28{,}274 \times 400) \div 33{,}000 = 291.3$ hp. The total power for the two cylinders is, therefore, $2 \times 291.3 = 582.6$ hp.

QUESTION — *What circumstances would guide you in deciding as to the quantity of air necessary for the ventilation of a mine?*

ANSWER—The volume of air circulating in a mine must first be sufficient to comply with the requirements of the state mining law. In addition to this, the volume must be sufficient and the air current so conducted as to sweep the working faces, in every part of the mine, and keep them free from gas and safe for work. The factors that decide the quantity of air required to accomplish this are the size of the workings; sectional area of the airways; thickness of the seam, as affecting the area of the openings through which the air currents pass and determining the velocity of the current. The velocity of the air must always be sufficient to act effectually in removing the gases that would otherwise accumulate in the workings.

National Coal Association Suggests Investigation of Seven Fundamental Points by Coal Commission

By Paul Wooton
Washington Correspondent of *Coal Age*

In a communication to the U. S. Coal Commission dated Nov. 10, in reply to a recent letter asking for suggestions "as to the best means of ascertaining the facts pertinent to the investigation into the bituminous industry," seven fundamental points are suggested by the National Coal Association as subjects to which the President's coal commission should give particular attention. They are:

1. The effect on production and on the price of coal, to the consumer, of the monopolistic and absentee control of mine labor.

2. The opposition of organized labor to the introduction of labor-saving machinery.

3. The non-observance by organized labor of contracts made on its behalf.

4. The existing prices of mining materials and supplies and a comparison between them and the prices existing prior to the war.

5. The existing freight rates and a comparison between them and the rates existing prior to the war.

6. The effect of inadequate transportation facilities on the production and the cost of coal.

7. The character and quality of the different coals, the uses to which they are put and the demand therefor.

The most careful attention was given by the National Association to this document. It was formulated from separate drafts presented by the different groups of operators. John W. Davis, former Ambassador to Great Britain and former Solicitor General of the Department of Justice, who has been retained by the association as its advisory counsel, assisted in the preparation of the document.

Alfred M. Ogle, president of the National Coal Association, met with the Brydon committee when the report was approved. At the close of the meeting he declared that coal operators generally are convinced that the President's commission is going to do a constructive piece of work. He said that the National Coal Association is more than anxious to co-operate with the commission in the most cordial and effective way possible.

The gist of the reply of the bituminous operators' special committee, composed of J. C. Brydon (chairman), J. G. Bradley, Michael Gallagher, Tracy W. Guthrie, George B. Harrington, E. C. Mahan and H. N. Taylor, is as follows:

This committee of the National Coal Association, and the bituminous coal operators co-operating with it, representing a preponderance of the tonnage of the industry, has received your letter of Oct. 24, 1922, on the subject of the approaching inquiry and respectfully submits its reply. The committee appreciates this opportunity to present in advance the views of the bituminous operators and begs to assure the commission of its earnest wish and the wish of those whom it represents to lend to the commission every assistance in its power.

With this purpose in mind the committee comes without further preface to the task of making responsive answers to the concrete topics enumerated in the commission's letter, taking each by the number assigned to it and answering the committee's questions A and B with reference thereto, and thereafter turning to questions C, D, E and F.

1. *"Ownership and titles of the mine."*

We suggest that a list of all the coal operating companies, individuals and partnerships be secured from the U. S. Geological Survey and that a card be prepared and mailed to each of said operators asking them to fill out the same and return to the commission with the following information:

(1) List of mines operated, acreage of each and showing as to each whether operated as lessees or by owner of the fee, and if as lessee, the name of the lessor.

(2) Thickness and name of seam or seams and in what coal field and district located and served by what railroad and at what shipping points.

(3) Whether operating under contract with United Mine Workers of America or not.

Since the sources of information and the methods of investigation in the union and non-union fields will necessarily be materially different, it seems to us that the first classification of mines made by your commission will be "union" and "non-union" mines and we therefore recommend that this information be obtained by the first questionnaire sent out, and so we have no hope only with the request for information as to titles and ownership.

2. *"Prices of coal."*

This information may be obtained from each individual operator. We know of no common source which can supply it.

3. *"The organizations and persons connected with the coal industry."*

Literally speaking, this involves owners and all employees at each individual mine, the railway companies, selling agents, brokers, dealers, wholesale and retail, and delivery contractors, with the organization, personnel and employees of each, as well as ship and dock owners.

This information can be obtained in full only from the organizations and individuals above referred to. No doubt such organizations as the National Coal Association, the National Retail Coal Merchants' Association, the American Wholesale Coal Association and the United Mine Workers of America can be of assistance.

4. *"Cost of production."*

(a) Since the methods of bookkeeping obtaining at different mines are divergent, we believe that the detailed reports required under this head should be consolidated to as few items as possible, consistent with obtaining the desired information, and we suggest the following: Labor, material and supplies, royalty, depletion, depreciation, general insurance, workmen's compensation or employers' liability insurance, taxes, including federal taxes assessed against the year's business in which the cost was incurred, general expense or overhead, interest on invested capital and miscellaneous charges.

(b) This information will be complete only if secured from all mines and may be obtained by a questionnaire as outlined in the method suggested for obtaining information as to ownership, and to show the radical changes in cost, should cover a period of ten years. In coal fields where trade associations exist this information might perhaps be obtained through them.

5. *"Profits realized by operators or owners of said mines during the last ten years."*

(a) Transcripts of the profit and loss accounts appended as may be necessary to secure uniformity.

(b) Where not published, this information can only be obtained from the individual operator. To be of value it should be secured from all mines since profits realized depend not alone upon working conditions and physical surroundings but upon management, marketing and many other factors. One mine cannot fairly be taken in this respect as fixing a standard even for its neighbor.

No Suggestion on Obtaining Data on Profits

6. *"Profits of other persons or corporations having to do with production, distribution or sale of coal."*

(a) This would include the companies or individuals to whom royalties are paid. It would, also, include transportation companies, whether railroads or shipping, both on the lakes and in the coastwise trade, together with incidental services rendered them by others. It, also, includes general selling agencies and brokers, dealers, wholesale and retail, and persons engaged in the business of delivering coal from the cars to the bins of the consumers, as well as those rendering these incidental services.

(b) We find ourselves unable to offer any suggestion as to how the information may be obtained, except from organizations and individuals mentioned.

7. *"Labor costs."*

(a) This is one of the details under Topic 4, and need not be further discussed here.

8. *"Wages paid."*

(a) Rates of wages paid can be obtained from copies of the wage scales for the past ten years. The commission should secure payrolls showing actual earnings. The running time of the mine during the period covered by the payrolls secured should also be obtained, together with the time worked by each employee as well as the tonnage produced.

(b) The wage scales and payrolls can be secured from the operators direct or from secretaries of trade associations.

In the consideration of this matter the attention of the commission is particularly called to the frequent failure of the employees to avail themselves of the opportunity to work and steps should be taken to ascertain how much of the irregularity is voluntary on the part of the employee and how much of it is due to inability of the mine to run, either for lack of transportation or lack of orders, or mine disability. The commission is especially invited to make a careful comparison of wages paid in the coal industry with the wages paid for similar labor in other industries.

9. *"Wage contracts."*

(a) The commission should obtain copies of all wage contracts in effect during the past ten years. It should examine the provisions, the history of each contract, their bearing, observance and violation, and where they provide for the suspension of operations, methods of such suspension and the manner in which these large sums of money are collected have been paid.

(b) This information can be obtained from the secretaries of the various trade associations in the different coal fields where these contracts have been obtained or from the officers of the United Mine Workers of America, at Indianapolis, Ind.

10. *"Irregular production."*

(a) The commission should obtain the number and working time of each mine for a period of ten years, and the causes of all failures to work full time.

(b) This information may be obtained from the operators and from the records of the U. S. Geological Survey.

11. *"Waste of coal."*

(a) There are a broad economic question involving many different things, such as to production and consumption, such as for instance, mining loads, from standpoint and conserving seams, drainage from pillared area or waste, coal below drainage level, etc., which are sometimes entirely beyond the control of the operator, and the practical problems of handling in transportation and how far it is practical and important economy of use.

(b) As to mining losses, many operators have this information. Some information may be obtained from the U. S. Geological Survey and some from the coal trade.

families live better than other families of the same size on the same of a lesser income.

Undoubtedly men are entitled to an opportunity to earn a fair and honest support for themselves and their dependents. The cost of such a living can be standardized, however, only when all the factors which enter into it can be separately standardized as well, and when individual appetities and desires and habits can be reduced to a like uniform rule.

As to living conditions which must be supplied or offered, in order to surround the workman with reasonable comforts, it is respectfully suggested that, under present conditions and conditions existing for some years past, the competition among employers for capable workmen has been such that, even aside from their desire to furnish proper working conditions and surroundings, they have been obliged to do so, in order to obtain and hold efficient employees.

It is suggested, however, that the commission might well make an investigation of representative communities in the various coal fields and elsewhere in order to determine what the living conditions of the workmen are as compared with those in other industries and in other centers of population, having reference, among other things, to cost of domestic supplies, size and kind of houses, cost of rent, electric lights, coal, water, medical service, nursing, and to school, church and recreational facilities.

Much of the work in and around coal mines is piece work, and the prices paid therefor are to a certain extent, standards. As to other work, it is of such varied character and done under such diverse conditions that standardization of any kind, as to the amount of work a man should do, is impossible.

We fully recognize that proper surroundings and living conditions are indispensable to both the happiness and efficiency of the employee, and the industry will welcome any suggestions which the commission may make looking to this end.

Standardization Declared to Be Difficult

19. "*Standardizing a basis of arriving at the overhead cost of producing and distributing the coal including delivery at the door of the consumer, recognizing in this compilation that the standardized cost of living to the miners should be the first and irreducible item of expense.*"

The principle governing the determination of what may properly be included in "overhead" is that there shall be included therein those fixed charges which continue constant irrespective of the volume of the business. Such charges are not subject to the fluctuations which characterize the items of cost hereinbefore alluded to and are not affected by variations in production. They fairly embrace costs of management, office expenses, interest on borrowed money, insurance, taxes and expenses incident to the organization as such. Standardization of such items if not wholly impossible, presents obvious difficulties.

As to standardizing the cost of delivery at the door of the consumer, attention is called to the fact that the cost necessarily varies for many reasons even for identical service in different parts of the country, so that it seems to us impossible to approximate any standardization. The dealers of the country can undoubtedly give the commission light on this complex question.

We now take up your questions (c), (d), (e) and (f).

(c) "*What, if any, topics should the commission investigate, in addition to those already enumerated in the law, in order to give to Congress and the public complete information necessary to the proper understanding of the conditions in the coal industry?*"

Since the creation of this commission was, unquestionably, due to the recent interruption of the supply of coal to the consumer, and its effect on prices, which in turn was due to the enforced closing of many of the mines during the past summer, we respectfully suggest that, because they strongly influence these prices, the commission should make investigation, in addition to those prescribed by the statute, of the following subjects:

(1) The effect on production and on the price of coal, to the consumer, of the monopolistic and absentee control of mine labor in the United States.

(2) The opposition of organized labor to the introduction of labor-saving machinery.

(3) The non-observance by organized labor of contracts made on its behalf.

(4) The existing prices of mining materials and supplies and a comparison between them and the prices existing prior to the war.

(5) The existing freight rates and a comparison between them and the rates existing prior to the war.

(6) The effect of inadequate transportation facilities on production and cost of coal.

(7) The character and quality of the different coals, the uses to which they are put, and the demand therefor.

(d) "*To what extent are you in position to co-operate with the commission in securing necessary data in such manner as will eliminate, in the largest possible degree, any basis for criticism of the accuracy or the validity of the data when secured?*"

The National Coal Association by this committee as its representative desires to co-operate with you to the fullest extent in its power, and to that end will use all the influence which it has with those whom it represents. However, as a voluntary organization it has no power to compel the giving of information. It may be well to state in this connection that the bituminous coal industry is a highly competitive business. The individual operators have always carefully guarded from each other the details of their business and have been advised that under existing legal prohibitions the interchange of information and its compilation by a central bureau might expose them to criticism. The association, therefore, is without any statistical information immediately available for the use of the commission.

In the interest of accuracy all information should be collected and compiled by separate districts. In those districts where both union and non-union mines are encountered a separate classification should be made for each.

(e) "*What, in your judgment, are the elements that have caused, and are causing the acknowledged demoralization in the coal industry and which are working hardship alike upon the parties engaged in the production of coal and the consuming public?*"

In our judgment, the bituminous-coal industry cannot fairly be said to be in a condition of "acknowledged demoralization." In spite of the recent difficulties, the industry in the main is neither wastefully nor inefficiently conducted and the service rendered to the public will, we believe, compare favorably with that of other industries in the country. Undoubtedly the industry still suffers in common with the entire commercial structure of the country from the disturbances and dislocations caused by the war. Prior

to the war, while strikes had occurred from time to time, it is fair to say that the country had never known distress or anxiety concerning its supply of bituminous coal.

The regulations brought about by the war and the governmental control to which the industry was then subjected disturbed its normal functioning. Inevitable concessions were made to labor in the matter of wages and working conditions, which, while perhaps appropriate in the circumstances then existing, should not continue now that the country is adjusting itself to a peace basis. The realization of this fact not only by the operators but by the employees and by the public, as well, is indispensable to the health of the industry. Above all things else, the industry needs a period of tranquillity and freedom from governmental interference or control. Time and the natural operation of economic laws can accomplish more for all concerned than any artificial efforts, either statutory or otherwise.

Such difficulties as exist we believe to be primarily due to the following elements:

(1) The monopolistic control of mine labor by absentee union officials.

(2) Nationwide as well as local strikes brought about by an irresponsible and autocratic organization.

(3) Lack of adequate railroad service and transportation.

(4) Unnecessary and uninformed competition among the buyers of coal.

(5) Appeals by agitators and propaganda of different kinds designed to breed dissatisfaction and create unrest among the people at large. It is earnestly hoped that the report of this commission will terminate once for all the misrepresentations on which these appeals are based.

(f) *"What in your judgment are the practical remedies which would eliminate any or all of the elements which you feel are responsible for the conditions?"*

We note with reference to the above query, as well as to the one which preceded it, that the commission, in suggesting that it be answered at some date in the near future, and then only tentatively, appreciates the difficulties which surround any effort to make a categorical response. The undersigned are not prepared at the moment to return any other than a general reply, reserving the right with the consent of the commission to amplify their views as the investigation proceeds.

In any discussion of remedies, however, we believe that there are certain basic principles which cannot be ignored, and which must condition any consideration of remedies. Among these principles are the following:

First—That every man has a right to work without either interference or compulsion when, for whom and upon such terms as he may see fit.

Second—That while the right of workers to organize for legitimate purposes cannot be denied, such organizations have no right to impede or restrain those who do not care to join or to deal with them.

Third—That the right of private property is and must remain inviolable.

Fourth—That in the last resolve, the law of supply and demand always has and always will determine prices; that no legislation can long interfere with this inexorable rule; that any interference can only be justified, if at all, in time of war; and that at any other time it will inevitably produce greater evils than those which it seeks to suppress.

Instead, therefore, of seeking remedies of a character which are foreign to the genius and spirit of our American institutions, as well as doubtful from the point of view of economics, we submit that a discussion of remedies should be directed to the two things most needed in the coal industry.

These are:

First—Adequate transportation.

How far the questions here involved are within the scope of this inquiry is, of course, for the commission to determine. The coal industry in the United States cannot prosper without a continuous, regular and adequate supply of the means of transportation. The railroads of the country should be given sufficient freedom, independence and revenue to enable them to obtain the money necessary to provide proper equipment and other facilities to meet their increasing business. They should be regulated only to the extent necessary to insure the proper use and distribution of those facilities when obtained.

Second—Freedom from labor troubles artificially promoted.

No organization or combination of persons, either natural or corporate, should be permitted to hold itself above and superior to the law. There is no room in this country for the doctrine of irresponsible power. The United Mine Workers of America and all like organizations should be subject to all statutes passed for the public good, and, specifically, to those forbidding the unreasonable restraint of interstate commerce, and any action taken by that or like organizations, the necessary result of which would be to restrain, destroy or impede interstate commerce, should be presumed in their case, as in that of others, to have been taken with that intent.

In soliciting the right to make such further communication to the commission as may seem expedient we renew the offer of such assistance as may lie within our power.

Bituminous Shortage Now Thought Unlikely; Some States May See Anthracite Scarcity

The stock report issued by the Federal Fuel Distributor discloses an unexpectedly large accumulation of bituminous coal. It demonstrates that the country came through the emergency with larger reserves than even the highest estimates. The report carries rather impressive confirmation of the experience in 1920 that the market becomes panicky when stocks begin to reach the 20,000,000-ton level. It now is clear that stocks were reaching that mark this year when the situation became acute and H. B. Spencer was called in to handle distribution. With this confirmation, it is being assumed by federal officials that 20,000,000 tons is the danger line.

The report shows that stocks had increased to 28,000,000 tons by Oct. 1 and, according to Mr. Spens' estimate, aggregated 35,000,000 tons on Nov. 1. The general opinion is that this estimate is entirely reasonable.

The steady gain in the output of bituminous coal indicates that with good management the country will be able to go through the winter with no serious shortage of steam coal. The stock report shows, however, that the process of substituting bituminous coal for anthracite had not proceeded far on Oct. 1. Retailers had increased their deliveries of bituminous coal in anthracite-consuming territory, but the increase was not sufficient to make up for the decrease in the amount of anthracite that would be available. The figures showed that the total deliveries of both anthracite and bituminous coal were less this year than last. A careful study of the figures reveals that in some states the work of substitution had gone further than in others. Substitution was further advanced in Rhode Island, New York, New Jersey and the District of Columbia. This is believed to be a direct reflection of the policy of local fuel administrators to urge substitution. It is predicted that as a result of this forehanded policy those areas will be spared the difficulties certain to come in other areas during the next five months.

The problem of domestic supply in those localities which will not receive their regular quotas of anthracite is believed to be largely one for local solution, which must be worked out through co-operation of retailers with local authorities. This winter, it is generally believed, will give a splendid demonstration of the indispensable service which the retailers perform in the distribution of coal. Officials believe that an unusual opportunity will be presented for the retailers to do a great public service and demonstrate that much of the criticism which has been hurled at them is not justified.

Recrudescence of National Coal Association Seen in Joining of Indiana Operators

The Indiana Bituminous Coal Operators' Association has filed an application for membership in the National Coal Association. This will bring into the latter association all operations in the State of Indiana. Under the conditions existing previously when Indiana was represented in the National Coal Association by the three coal trade bureaus, 40 per cent of the state's tonnage was unrepresented.

This action, together with the fact that the Illinois operators and those in the Pittsburgh district recently have been co-operating with the association in important matters, leads to the belief that the National Coal Association soon will be stronger and more representative than ever before.

Some are of the opinion that the action of the Indiana operators foreshadows a similar course on the part of those in Illinois. It is known that the more substantial operators in Illinois are fully aware of the essentials of a truly representative national organization.

A new recognition of the importance of the National Association is in evidence in all of the fields which have membership. It is declared by association officials that an exaggerated importance was given the defections in membership which followed the Indianapolis conferences and the Supreme Court's decision in the Hardwood case. Since those developments affected adversely many of the organizations holding membership in the National Coal Association, there naturally was uncertainty until new bases of national representation could be worked out.

J. D. A. Morrow will be relieved of his duties as vice-president of the National Coal Association on Dec. 1 so that he may devote his entire time after that date to the newly formed coal-brokerage firm of which he is president. No successor for Mr. Morrow has been chosen as yet. Since the success of the organization depends to such a great extent on the vice-president in charge of the Washington office, the committee charged with the selection of that official expects to take whatever time may be necessary to find the best available man qualified for the position.

Three Central Pennsylvania Operators' Associations Amalgamate

The Central Coal Association, the Central Pennsylvania Coal Producers' Association and the Association of Bituminous Coal Operators of Central Pennsylvania were amalgamated at a joint conference of directors of the three associations held in Altoona Nov. 9.

The Central Coal Association and the Association of Bituminous Coal Operators merged under the name of the Association of Bituminous Coal Operators of Central Pennsylvania and all the members of the merged bodies became members of the Central Pennsylvania Coal Producers' Association. This action will give the operators in this region one of the strongest organizations in the United States.

The Producers' Association will have charge of such matters as traffic, car supply and the collection and dissemination of statistics and various information of interest to the members. It will have nothing whatever to do with matters pertaining to labor problems. The Association of Bituminous Coal Operators will have but one purpose, the negotiation of and the enforcement of wage agreements between the operators employing union labor and the United Mine Workers.

The general officers of both associations are the same under the terms of the amalgamation, as follows: President, B. M. Clark, Indiana; Vice-President, G. Webb Shillingford, Clearfield; Secretary-Treasurer, Charles O'Neil, Altoona; Commissioner, John C. Forsythe, Clearfield; Statistician, W. A. Jones, Altoona.

The executive board of the Association of Bituminous Operators will be B. M. Clark, Indiana; Rembrandt Peale, New York; J. R. Caseley and E. H. Robertson, DuBois; C. B. Maxwell, Morrisdale; H. B. Scott and J. William Wetter, Philipsburg; Thomas F. Kelley, Coalport; G. Webb Shillingford, Clearfield; J. S. Sommerville, Robertsdale; William Lamont, Elmora; J. A. Boucher, Beaverdale; Harry Boulton, Clearfield; S. T. Brown, Indiana, and M. J. Brecken, Johnstown.

The board of the Producers' Association is composed of the following: Tyrone group, J. W. Wetter; Clearfield group, R. H. Sommerville; South Fork group, M. J. Brecken; Barrensberg group, James H. Allport; Tioga group, E. H. Robertson; Broad Top group, J. S. Sommerville; Punxsutawney group, W. R. Craig; Directors at large, G. Dawson Coleman, Philadelphia; D. T. Price, Windber; Charles A. Owen and Rembrandt Peale, New York; B. M. Clark, Indiana; J. R. Cooley, DuBois; James B. Neale, Minersville; J. W. Shillingford, Clearfield; W. S. Blaisdale, Punxsutawney; Fred B. Kerr, Clearfield; C. B. Maxwell, Morrisdale; Harry Boulton, Clearfield, and S. T. Brown Indiana.

Toll of Lives in Reilly Mine Disaster, At Spangler, Pa., Is Seventy-Seven

Seventy-seven lives were lost in the Spangler, Cambria County, mine disaster of Nov. 6, according to the official figures announced by Seward Button, head of the state Bureau of Mines of Pennsylvania, who has been in charge of the investigation and who has completed an exhaustive checking up of the Reilly company's payroll and the weighmaster's list of miners.

Mr. Button's report states that 100 men entered the mine the morning of the explosion. Following the explosion, six escaped, twenty-one were rescued and taken to the hospital and seventy-three dead bodies were taken from the mine. Four of those taken to the hospital died and five more are in a critical condition.

Following a conference with the mine officials, who had requested him to put the mine in condition to enter in order to facilitate the work, Mr. Button appointed the following commission to make a thorough inspection: W. D. Wardrop, district inspector; Thomas Lawther, Johnstown; Charles Crooker and T. D. Williams, Johnstown; Thomas Mallon, Tyrone, and Joseph Williams, Altoona.

Thursday, Friday and Saturday were given over to the funerals of the deceased miners. Relief work for the families of the stricken miners has been started and is receiving whole-hearted support. The Red Cross has opened welfare stations and the people of Johnstown, Altoona and the smaller towns in the district and the various coal companies throughout the district are giving freely of money and other necessities. The United Mine Workers has contributed $10,000 for relief work at Spangler. Of this amount $5,000 came from the international organization at Indianapolis and $5,000 from District No. 2, at Clearfield.

The relief committee is composed of John Mayholtz, an organizer for the U.M.W.A.; James McGlenn, president of the Spangler local of the U.M.W.A.; A. E. Fox, president of the Spangler chapter of the Red Cross, and Mrs. Harry Blair and Mrs. W. R. Davison.

After a two-day investigation of the mine, Chief Seward Button attributes the explosion to methane gas. In a preliminary report, Mr. Button stated the actual explosion was slight and but few men were killed in that manner. Most deaths were due to the presence of after-damp and the inability of the men to reach fresh air. The inquest will be held early this week.

George S. Rice, chief mining engineer of the U. S. Bureau of Mines, and J. W. Paul will make a special investigation of the disaster for the Bureau of Mines.

Ohio Administrator Allows Advance of 50c. in Price of Domestic Sizes

Late last week the Ohio Fuel Administrator authorized an increase of 50c. in the fair-price schedule for "coal in sizes specially prepared and particularly cleaned for individual purposes." This increase is made in order to assure to Ohio users a fair percentage of the lump produced within the state which has been going to outside purchasers. According to Administrator Neal the former fair-price list took into consideration only actual cost of production without allowing for labor operations necessary for special preparations. The administrator also authorized the new Pocock Coal Co. and Howells & Fox, coal operators in the Massillon field, to raise their mine price from $4.86 to $5.11 because of high cost of production.

All specially prepared domestic coal coming within this order will be priced from $5.06 to $5.61 under the new ruling. The price in the Hocking Valley proper, including Hocking and Athens counties and Monroe township, in Perry County, will be increased from $4 to $4.50 while the Bailey Run, or No. 7, seam will be increased from $4.59 to $5.09.

Ohio Coal Companies Seek to Enjoin State Control of Fuel

A sweeping injunction which, if granted, will tie up all of the machinery of the State Fuel Administration and stop, temporarily at least, all efforts to enforce coal price regulation in Ohio, is asked in a suit filed Nov. 8 in U. S. District Court at Toledo. The Ohio Collieries Co. and the George M. Jones Co., two Toledo companies which control sixteen mines in the southern Ohio field, seek the injunction.

The bill of complaint attacks the constitutionality of the emergency act passed by the Legislature late in the summer providing for the appointment of a fuel administrator and state regulation of the price of coal.

The bill names Roy R. Stuart, prosecuting attorney of Lucas County; Governor Harry L. Davis and Attorney General John G. Price. After receiving the petition for the injunction, Judge John M. Killits announced that he would take no action relative to a hearing until he had conferred with the other District Court jurists as to the legality of the procedure.

As the bill attacks the constitutionality of a statute of the state, the hearing upon the application for a temporary injunction and the final hearing upon the merits must be before a court consisting of three United States Judges.

The bill declares that the Ohio Collieries Co. cannot operate its mines at a profit at the price fixed by the Ohio Fuel Administrator.

Operators Offer Two Wage Plans at Chicago Conference; Lewis Has No Definite Proposal

When the joint committee of operators and miners assembled in Chicago Tuesday, Nov. 14, to begin its efforts to work out a wage plan for the future it had before it at least one definite suggestion. Harry Taylor, of the Southwest Interstate Association, proposed a scheme whereby wages by districts could be varied from a "national base rate" according to local conditions, and setting up joint boards to adjudicate disputes and a supreme council for appealed cases. This plan put the outlying districts in the position of presenting something constructive as a contribution at the first national conference of the sort to which they had ever been admitted.

Preceding the conference there was a quite general sentiment that a strong national organization of operators to deal with the miners' union should be formed at once and steadfastly supported when the meeting started. Nobody knew what it would do after its organization nor how long it would run.

Every one of the fifteen districts represented at the Cleveland conference a month ago, which arranged the Chicago meeting, had its delegates in Chicago when the session opened. No other regions asked admittance after the Cleveland organization was made permanent with Phil Penna as chairman and William Green, of the miners, and E. G. Edwards, of the operators, as secretaries. Little was done at the morning session except receive credentials before adjournment at noon.

One dispute arose when both Joseph Purseglove and M. E. Watson, president of the Monongahela Coal Association, claimed to be official delegates. Purseglove was the man representing several large producers of that field at Cleveland but Watson put in his claim on the basis of his selection by the Monongahela Coal Association on Nov. 9. The dispute went to secretaries Green and Edwards. Mr. Purseglove was not in Chicago because of an accident suffered by his daughter but his case was put in by his brother, Sam Purseglove. The two secretaries, unable to reach an agreement, laid the case before the conference when it convened for the afternoon session.

W. L. Jenkins, of Fairmont, W. Va., read to the operators a plan for national agreements to be made by a nationwide conference committee.

At the afternoon session both Purseglove and Watson were accepted as delegates, each with half a vote. This was not expected to cause confusion because each district must vote as a unit.

The miners remained but three minutes in the afternoon meeting, retiring after President John Lewis said he had no definite proposal to make. The operators then spent all afternoon discussing the plans proposed by Mr. Taylor and Mr. Jenkins, reaching no agreement on them and giving no publicity to either but referring both to a committee to report Wednesday.

It was hoped Lewis would have something definite to propose by Wednesday's joint session. Tuesday night he said he was waiting for the operators. Thus the first day accomplished little. When Mr. Lewis was asked if the conference might wait for the Federal Coal Commission to produce a wage plan he smiled and said there wasn't much use expecting anything.

Preliminary Statistics of Production of Coal in 1921

(Exclusive of product of wagon mines)

Union Miners to Be Assessed $2,000,000

A special assessment on members of the United Mine Workers of America which is expected to yield to the union's treasury at least $2,000,000 is announced by John L. Lewis, international president.

While reluctant to discuss the possibility of another strike, Mr. Lewis said that the miners would not accept any wage reductions on April 1, when the present agreement in the bituminous coal fields expires. The union demands continuation of the present wage scale for another two years.

Mr. Lewis said that coal production was being speeded up throughout the country and was being limited only by transportation facilities. Virtually all the miners in the unionized districts, he said, were working, but there were still 75,000 miners out on strike in the non-union coal fields.

"Never before in its history was the miners' union in better condition than it is today, although the battle with the non-union operators continues to be waged all around our borderland," said Mr. Lewis, "and all the fighting is being done on the enemy's territory.

"We are taking care of the financial situation by levying a special assessment of $4 per member, to be paid in two instalments of $2 a month."

Coal Miners Remain Idle Rather Than Work in Metal Mines

Metal mines in the Butte district are in urgent need of no less than 3,500 men, according to reports to federal officials. As there are several hundred men awaiting work at coal mines in Wyoming, an effort has been made to induce the unemployed in the coal fields to accept positions at Butte, but since the wages in the coal mines are so much higher, the men in most cases prefer to stay at the coal mines and take the chance of employment developing. Reports from Eastern coal mines indicate that men are applying for work in much larger number than they can be employed.

Much Legal Jockeying Marks Early Stages Of Trial in Herrin Massacre Case

Trial of men indicted for murder in connection with the Herrin massacre in Williamson County, Illinois, is getting under way amid difficulties. Most of the men in the venire of 150 avoided jury duty in the case on one excuse or another as a starter. When the Attorney General moved to *nol pross* the indictments against 41 of the 46 men the grand jury held for the murder of Howard Hoffman, A. W. Kerr, chief counsel of the defense, employed by the miners' union, insisted that a jury be impaneled at once and instructed to find the 41 "not guilty" and to release them. The objection was overruled and 5 men of the original 46 will stand trial for Hoffman's death as soon as the jury is chosen.

The defense moved for a continuance of the case to the next term of court, but Judge Hartwell insisted that as both sides originally said they would be ready now, the trial should proceed. Next the defense moved that all the indictments be quashed on the ground that the grand jury that returned the indictments was selected by sheriff's deputies instead of by the sheriff himself, that 26 jurors instead of 23 were summoned and that the jury had been unduly influenced during the deliberations by statements printed in the newspapers. Judge Hartwell reserved decision.

Attorney Kerr for the miners demanded the right to question the prosecution as to the source of the funds which private organizations have put into Attorney General Brundage's hands, in lieu of state funds which are not available because Governor Small cut so deeply into the Attorney General's appropriation. Judge Hartwell denied this motion. With the removal of all objections and motions tending to delay the trial, the case is ready to proceed. Early this week it was thought that the choosing of the jury would be resumed. How long it will take to impanel a full jury remains to be seen. Frank Farrington, president of the Illinois district of the United Mine Workers of America, and State Senator W. L. Sneed, a subdistrict president, are both in attendance at the trial.

Coal Roads Announce Further Plans for Improving Their Freight Facilities

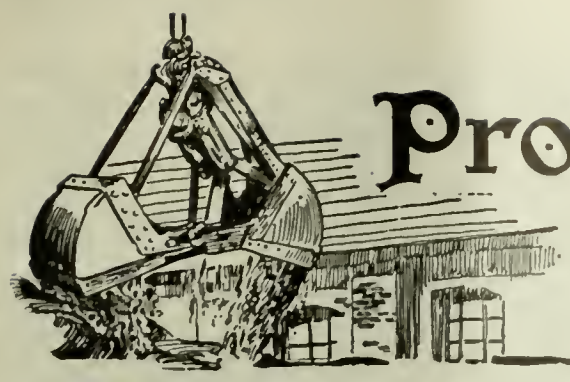
The Louisville & Nashville R.R., which to Nov. 1 had reported contracts of over $20,000,000 placed this year for road improvements, cars, engines, etc., has since announced contracts placed for 3,000 more cars, including 2,000 coal cars, to be delivered by April, 1923, these to be all steel cars. The road contracts the 3,000 cars at $5,750,000. At present the L. & N. has 27,750 coal cars and 17,750 box cars. W. L. Mapother further announced that he plans to spend a total of $52,000,000 in 1922 and 1923 in improving facilities of the road for handling traffic, which should bring relief to many shippers.

On Nov. 6 announcement was made that the Chicago, Indianapolis & Louisville R.R. (Monon) was spending $725,000 for 300 steel coal cars, 7 locomotives and 4 steel coaches. The Illinois Central R.R. also has filed a trust agreement at Frankfort, Ky., under which a mortgage agreement is uncovered with the Commercial Trust Co., of Pennsylvania, whereby the road is to receive money for purchase of $8,310,000 worth of equipment, including 3,000 steel coal cars, 50 road engines and 15 switch engines.

Professor Willitts to Probe Wage Facts For U. S. Coal Commission

Fact-finding with regard to wages and earnings of mine workers will be done by Prof. Joseph S. Willitts, of the University of Pennsylvania, for the President's coal commission.

Since the commission has committed itself to await suggestions from the various branches of the coal business before formulating its own plan of action, no great amount of progress has been made during the past week in the formulation of its plans. The week has been spent, however, in informal conferences and consideration of the data which its staff already is laying before it.



A plan is being worked out whereby all material submitted by outside sources will be carefully checked so that the commission will be in a position to underwrite any of the facts and figures which it may care to use.

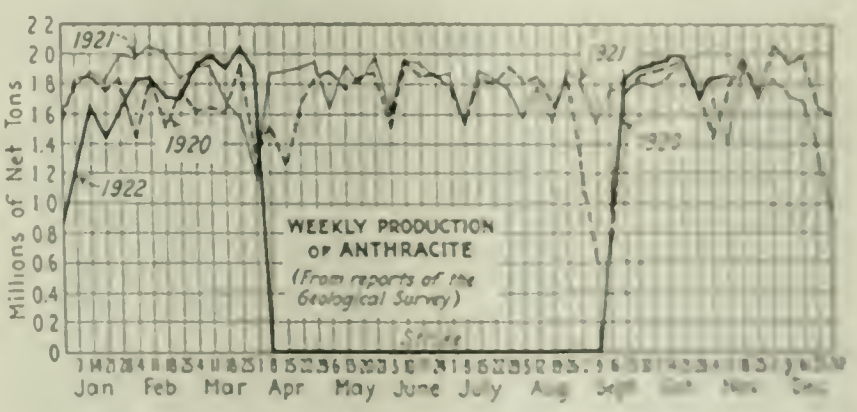
Production and the Market

Weekly Review

Conditions in the coal market are slowly improving. The trade shows an urgent need for a cold snap, but in spite of unseasonable temperature and other deterrent factors, prices are being held more and more firmly. *Coal Age* Index of spot bituminous coal prices dropped 4 points to 340 on Nov. 13, as compared with 344 in the week previous. This corresponds to an average mine price of $4.12 and is a decline of only 8c. since Nov. 1. During October the average spot price dropped 70c.

There are plenty of inquiries in the spot market and undoubtedly many users are quietly accumulating reserves. The heavier output is being sold with less difficulty, although the volume of spot offerings has not increased in like proportion. Much coal is moving to contract connections and the trade prefers to hold its free coal on the open market so but few new contracts are reported. High-grade fuels are eagerly sought, but the supply is very limited. Naturally this has improved the position of the medium and low qualities, although the market is still far from a "coal-is-coal" basis. The railroads are actively acquiring tonnage and much criticism is directed toward the carriers' system of preferential car supply for their needs. Operators assert that their commercial placements are so meager that they are unable to accept new business for delivery at an early date.

Rush Movement to Lakes Reduces Supply



So much coal has been concentrated on the Lakes that the available commercial supply has been materially reduced in the Eastern Inland section. This shortage was apparent last week and prices firmed up. Prices for last-minute Lake shipments, however, have broken under the heavy volume of tonnage moving to the lower ports. Lake coal will move from the mines up to Nov. 20, when it is estimated that sufficient tonnage will be rolling and on hand to supply cargoes during the balance of the navigable season.

The Middle West market is flat. Warm weather has dealt the coal man a severe blow and domestic demand has been slowed. Steam coals are in heavy oversupply in this section and despite some movement, all-rail to the Northwest, the number of no-bills in Illinois and Indiana producing sections is increasing.

Light receipts in North Atlantic markets suffice to meet current needs. In this as in other sections further west, the close of Lake navigation is being awaited by buyers, who feel that the release of this tonnage will soften the market considerably. A turn in the weather, however, which would also affect transportation conditions, would soon absorb this coal, and it is also quite likely that the re-entry of a large number of these dilatory buyers will have the same effect.

New England presents a featureless market. The all-rail demand is only fair and Hampton Roads is still topheavy with coal. The plenitude of supply for this section is so apparent that buyers are not interested in adding to their seasonal reserves.

The Lake season is blamed for a curtailment of domestic anthracite receipts in the Eastern section. Retail yard supplies are running down. As the shortage becomes

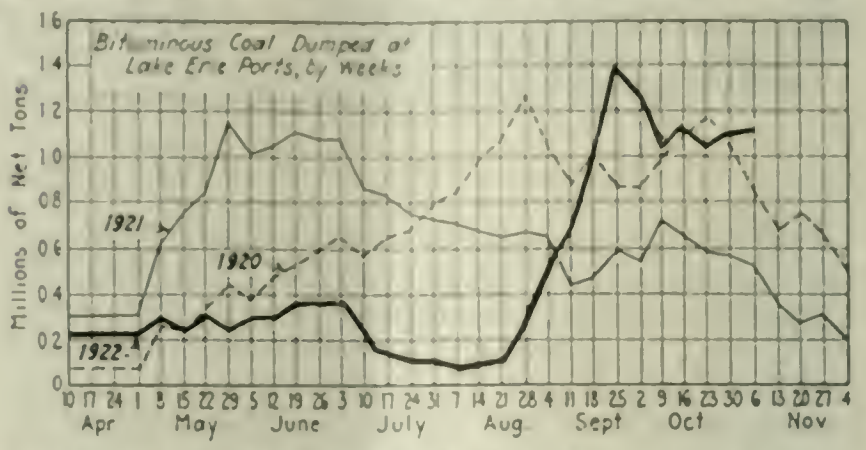
more apparent consumers are being urged to safeguard their needs with substitute fuel, although comparatively little of this is being sold. The acute domestic demand has aided the movement of pea and buckwheat, but the smaller steam sizes are still extremely draggy.



The coke market is more active, but spot prices have softened during the week. The amount of current offerings, however, is not large and coke users feel that it is not sufficient to encourage resumption of operations at plants now closed down.

BITUMINOUS

"Preliminary returns on coal loaded at the mines during the week ended Nov. 11 indicate a total production of 12,600,000 net tons, of which about 10,700,000 tons was bituminous coal and 1,900,000 tons was anthracite," says the Geological Survey. "Revised estimates for the week ended Nov. 4 show 10,617,000 tons of bituminous and 1,830,000 tons of anthracite. Thus a slight increase in the total coal raised is shown for the present week as compared with the week before.

"Loadings of soft coal on Monday, Nov. 6, as reported by the railroads, were 43,810 cars. On Tuesday, Election Day, loadings declined to 25,315 cars, but on Wednesday 33,875 cars and on Thursday 31,807 cars were loaded. The total for these first four days of the week is a little larger than for the same days of the week preceding.

"A canvass of commercial and industrial stocks of bituminous coal as of Sept. 1 and Oct. 1, undertaken co-operatively by the Bureau of the Census and the Geological

Survey, has shown that at the rate of production during the month of September consumers were able to add about 6,000,000 tons to their stocks. During October at least as much more was added to reserve piles."

Hampton Roads dumpings were 248,637 net tons during

Coal Age, Index 340, Week of Nov. 13, 1922. Average spot price for same period, $4.12. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions each of slack, prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

the week ended Nov. 9, as compared with 214,874 tons in the preceding week. The coastwise market is sluggish, but so much of the Southern fuels are moving to the West that prices at the piers are firm. Receipts of British coals are dwindling.

The last-minute rush of Lake coal has reduced the estimated shortage in the Northwest. Dumping during the week ending Nov. 5, were 1,088,104 net tons as compared

with 1,026,388 tons in the week preceding. The movement for the season to date—15,577,786 tons—compares with 21,972,395 tons in 1921. Unless the winter is unusually severe Northwestern consumers of bituminous coal should

Car Loadings, Surplusages and Shortages

	Cars Loaded All Cars	Cars Loaded Coal Cars
Week ended Oct. 28, 1922	1,014,450	197,928
Previous week	1,003,759	196,771
Same week in 1921	951,384	210,630

	Surplus Cars All Cars	Surplus Cars Coal Cars	Car Shortage	
Oct. 30, 1922 ..	3,716	1,584	179,239	47,273
Oct. 23, 1922	4,409	1,776	166,349	46,575
Same date in 1921	80,000	38,000		

be in a fairly comfortable position. Although the docks are going to be short, Illinois and other nearby mines can undoubtedly make up the deficit.

ANTHRACITE

Production of anthracite during the week ended Nov. 4, was 1,839,000 net tons. Preliminary returns for last week indicate an output of about 1,900,000 tons.

Demand is acute but the unseasonable temperatures have cut down the shortage, estimated earlier in the season at 40 per cent. Lake dumpings last week were 99,000 net tons as compared with 94,200 in the previous week. Steam sizes are slow with the exception of buckwheat, which is being better taken in conjunction with the domestic grades. Smaller steam coals already at New York Tidewater are in distress and some barley in loaded boats has gone for the freight charges.

COKE

Beehive coke production decreased to 217,000 net tons during the week ended Nov. 4, as compared with 287,000 tons in the week preceding. Connellsville production, however, increased 5,000 tons during the week. Demand is rather light, both from foundrys and furnaces. Those furnaces now out are actively making inquiries for lower-priced contracts in order to produce salable pig iron, but operators are holding these prices firmly.

October witnessed an output of byproduct coke larger than the monthly average for any preceding year. The total production was 2,806,000 tons, an increase of 563,000 tons, or 25 per cent over August, and of 226,000 tons, or 9 per cent, over last June, the highest preceding month of the present year. Production of beehive coke also increased and reached 878,000 tons, an increase of 74 per cent over the monthly average for 1921, but a decrease of 15 per cent compared with 1920.

MONTHLY OUTPUT OF BYPRODUCT AND BEEHIVE COKE IN THE UNITED STATES
(Net Tons)

	Byproduct Coke	Beehive Coke	Total
1917 Monthly average	1,879,000	2,744,000	4,623,000
1918 Monthly average	2,188,000	2,502,000	4,690,000
1919 Monthly average	2,093,000	1,650,000	3,743,000
1920 Monthly average	2,580,000	1,945,000	4,525,000
1921 Monthly average	1,648,000	682,000	2,330,000
September 1922	2,244,000	504,000	2,748,000
October 1922	2,806,000	878,000	3,684,000

(a) Excludes screenings and breeze. (b) Includes coke for local consumption.

The quantity of coal consumed in the manufacture of coke during October was approximately 5,410,000 tons, of which 4,032,000 tons were used in byproduct ovens and 1,384,000 in beehive ovens. These figures indicate that the present consumption of coal for coke manufacture is about two-thirds greater than during the period of extreme depression in 1921, and about 8 per cent less than in the active year 1920.

ESTIMATED MONTHLY CONSUMPTION OF COAL FOR MANUFACTURE OF COKE
(Net Tons)

	Consumed in Byproduct Ovens	Consumed in Beehive Ovens	Total Coal Consumed
1917 Monthly average	2,651,000	4,116,000	6,767,000
1918 Monthly average	3,072,000	4,054,000	7,126,000
1919 Monthly average	2,940,000	2,618,000	5,558,000
1920 Monthly average	3,624,000	2,917,000	6,541,000
1921 Monthly average	2,315,000	1,023,000	3,338,000
September 1922	3,153,000	756,000	3,909,000
October 1922	4,032,000	1,384,000	5,416,000

(a) Assuming a yield in merchantable coke of 68 per cent of the coal charged in byproduct ovens and 63 per cent in beehive ovens. (b) Revised from last report.

Foreign Market And Export News

British Market Improves: Industry Reviving in France

Influx of Orders Comes with Passing of Strike Fear in Wales—Production at Peak—Meager Receipts of Coke from Germany—Acute Coal Shortage in Germany.

British market conditions are decidedly improved. The labor situation in Wales is more tranquil. This has caused an influx of orders, the strike fear now having practically passed. Prices are stronger and production is at the high mark for the year.

A slight industrial improvement in France has aided the steam coals, while domestic sorts are in strong demand. Meager and inadequate coke receipts from Germany under the Reparation Agreement are reported and French furnaces are demanding an early upward revision of the schedule.

Germany is still in the throes of an acute coal shortage. Purchases of foreign fuels are imperative but are further depressing the value of the mark.

British Secure Many Belated Orders. Output Again Breaks Record

British production has again broken the record for the year. The output during the week ended Oct. 28 was 5,288,000 gross tons, according to a table in Coal Age, as compared with the high figure of 5,255,000 tons in the preceding week. Best grades are well sold up through the balance of the year. Top-heavy supplies of lower quality coals are weakening their position.

The improved labor outlook in Wales has resulted in a renewed influx of orders. Since the men have practically refused to strike over the nationalization question the industry has become more settled. Shipments to Canada are still substantial and it is said that Canadian buyers will want Welsh coal throughout the winter. Continental buyers have been holding up orders till the labor difficulties were over, and the Welsh pits now find themselves well booked.

The north English collieries are, with few exceptions, sold out for the rest of the year. The best customers are Canada and Germany. Latest contracts are for lots varying from 25,000 to 40,000 tons for delivery monthly at 22s. f.o.b. One firm alone has contracts with Durham pits for 200,000 tons for delivery during next year at prices around 21s. Prices are firm, and several descriptions are quoted at higher figures.

BRITISH COAL INDUSTRY LOSING MONEY

Official statistics for the twelve months ended June 30, 1922, show that during that period the profits of the industry as a whole amounted to about £9,000,000, compared with £28,000,000 guaranteed by the government to the owners during the period of control and with an average pre-war net profit per annum of about £18,000,000. This profit of £9,000,000, however, is more apparent than real. As part of the settlement of the strike in 1921, £10,000,000 was granted to the mining industry, and about £6,000,000 of the £9,000,000 profit was made during July and August, 1921, when this subsidy was in effect. Furthermore, owners have had to surrender £3,000,000 of the £9,000,000 to the miners to guarantee the minimum wage under the agreement of June, 1921. Under the agreement the industry was divided into thirteen districts, and of the profits shown, £6,830,000 was made in two of these districts only—the Eastern Federated Area and the Lancashire, Cheshire, and North Staffordshire Area. The former area alone showed a profit of £5,501,586.

Rise in British Coal Exports

During September Great Britian exported 7,082,729 gross tons of coal, compared with 6,146,121 in August and 3,406,579 in September, 1921. In 1912 the average value of British coal exports was just under 13s. 8d. per ton; now it is 22s. 7d.

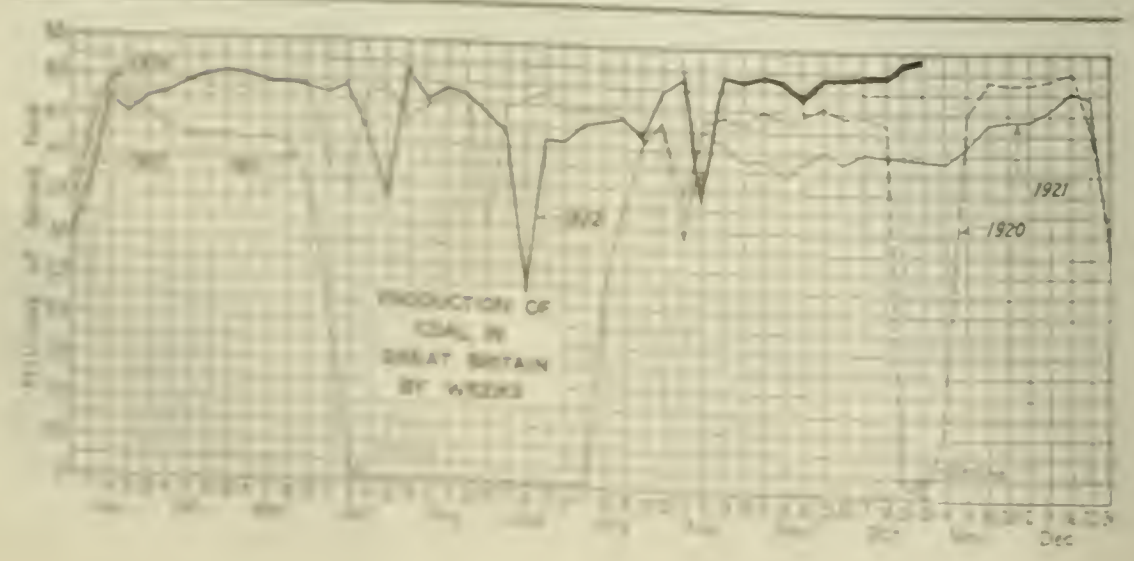
French Market Improves; Increased Reparation Tonnage Needed

Industrial demand is satisfactory, especially as regards gas and coking sorts, and stocks are decreasing. Several collieries have decided to start their coke ovens, and this will reduce available supplies of coking slacks. The rush for domestic continues unabated.



Belgian coalowners have caused a revision of outstanding contracts on the basis of the following increases: Nuts, 20 fr.; all other kinds of sized coals, 10 fr.; ovoid briquets, 18 fr. Parisian householders now pay, as from Nov. 1 270 fr. for Belgian nuts of half-fat coals; 183 fr. for French screened coal; 280 fr.@290 fr. for Belgian anthracite nuts; 370 fr.@410 fr. for Welsh anthracite nuts.

Newcastle or best Yorkshire coals are now quoted 34s. 6d. c.i.f. Rouen, which, at the present rate of exchange, is equivalent to 108 fr.@110 fr.

The output of the Lorraine and Sarre fields is increasing and a good part of it is absorbed by Germany. Loire and Center fields are aided by the present industrial improvement and stocks are decreasing.

The Commission of Reparations, which has provisionally moved to Berlin, will soon determine the future quantity of German reparation coal deliveries to the Entente. This had been fixed in August, at 1,725,000 tons per month for September and October, inclusive of 125,000 tons from Upper Silesia which Germany did not even attempt to deliver. It is probable that Germany will do her utmost to obtain a reduction and a very artful press campaign has been started to that effect.

After allowing for the present shipments to the Entente, the territories that now compose the Reich still claim for their consumption about 11,600,000 tons per month, while the corresponding figure in 1913 for the same territories was only 11,500,000 tons. As regards coke alone, the situation is still more favorable for Germany. The Entente demands now in force leave at the disposal of the present German territories a coke supply representing about 106 per cent of their pre-war requirements. At the same time, French blast-furnaces are only granted 79 per cent of the quantities of German coke de-

livered to them before the war, this proportion being still further reduced by the fact that Germany never delivers the whole of the tonnages due. French blast-furnaces, therefore, which cannot hope for a long time to obtain sufficient supplies of French coke, are forced to curtail their production, which is hardly 60 per cent of capacity.

German Prices Raised Again

Production in the Ruhr region during the week ended Oct. 28 was 2,005,000 metric tons, according to a cable to *Coal Age*. The output for the previous week was 1,989,000 tons.

Because of the large increase in the wage scale the coal prices have again been raised. Effective Nov. 1, an advance of 2,060M.@7,115M. per ton was made on unwashed fat coal.

The output of the Ruhr basin and Left Rhine collieries in September amounted to: Coal, 8 265,688 tons (8,336,773 tons in August) or 317,911 tons (308,769 tons) per working day; coke, 2,128,328 (2,176,208 tons) or 70,944 tons (70,200 tons per working day; briquets, 413,282 tons (375,191 tons) or 15,895 tons (13,896 tons) per working day, according to the *Colliery Guardian*. Only 52 per cent of the miners worked the overtime shifts in the latter half of the month, but the percentage has since increased to 77.5 per cent.

The Rhenish lignite district produced 3,234,961 tons of coal and 646,551 tons of briquets; and the Mid-German lignite mines, 8,074,105 tons of coal and 1,852 890 tons of briquets.

Coal Paragraphs from Foreign Lands

ITALY—The price of Cardiff steam first is now quoted at 40s. 3d. on the Genoa market, according to a cable to *Coal Age*.

A Milan note hints at a rise in coal prices, and advises consumers not to expect a reduction except such as may take place for a moment in consequence of a passing glut. This, on the other hand, may be easily absorbed by ready buyers.

Extensive development of power by utilization of the lignite deposits of Italy is being considered under the Government subsidy plan for making use of the national fuel resources, according to a report to the Department of Commerce by Consul Russell, Rome.

BELGIUM — The arrival of cold weather has still further increased the demand for domestic descriptions. Prices are firm and delivery periods are lengthening.

During September 1,751,210 tons of coal were extracted from Belgian mines as against 1,691,940 tons in August. On Sept. 30 stocks of coal stood at 758,070 tons, a reduction of 283,810 tons. Production of coke amounted to 239,260 tons compared with 245,040 tons in August and the production of briquets was 203,490 tons, as against 216,610 in August.

CANADIAN COAL IMPORTS for the first nine months of 1922 were 1,245,943 tons of anthracite and 5,417,975 tons of soft coal, as compared with 3,642 189 tons of the former and 9,896,760 tons of the latter during the 3-year average, 1919, 1920 and 1921, for the same period.

Featureless Market at the Roads

Continued dullness was apparent last week, with depletion in the coal supply. Shipments from the mines continued below normal, with supplies so scattered in the trade that no shipper had a normal quantity on hand.

Coastwise movement was still reduced, because of shipments to the West and Northwest. The trade was anticipating a decrease in this movement in the next two weeks, with a consequent revival of business here.

Trading Suffers Doldrums: Inquiries Are Plentiful

Current Demand Satisfied by Light Receipts—Early Improvement Foreshadowed—Stiff Undertone on Scarce Good Grades—Transportation Gradually Improving—Southern and British Receipts Dwindle.

Trading is still slow although there are plenty of inquiries. The light receipts are sufficient to meet current demand but there are many indications of an early betterment. Prices show little change, but good grades are so scarce that a stiffening tendency is evident.

As in other markets buyers are defending their dilatory attitude by the statement that they expect freer offerings after the close of Lake navigation.

Transportation conditions are improving slowly. Railroads are more active in the market and considerable complaint is heard from operators who are attempting to run on straight commercial business that preferential supply for carriers' needs leaves them but little loading equipment. Receipts of Southern coal are dwindling, while British cargoes are now arriving only occasionally.

PHILADELPHIA

There is no appreciable change in the situation. The light amount of coal coming upon the spot market seems to be entirely sufficient for the demand. It might be said that requirements for small shipments are inclined toward betterment, as the moderate users show an inclination to put by a little more coal.

There is no lessening of the complaint of car shortage by the producers, some claiming that it has grown worse. One firm is advising their trade as to mine follows and their mines had been closed for the eighth successive day, stating "I see no new favorable signs in the railroad or distributing cars we intend to even out, as we cannot exist under present conditions."

A large share of production is still going to the railroads for supply fuel. Most of the lines in the Northeast remain ordering the market strongly.

At Tide there is very little activity, outside of bunkering and this is somewhat light. No foreign coal is coming in, although there has been a stray cargo of Southern coal. It is of interest, though, to note the recording of a charter for a cargo of British coal, delivery to be made sometime in November.

Price changes have been few and are at the same level as a week ago. It must be noted, however, that coals of Pools 1 and 9 grade are somewhat scarcer, with an occasional light price advance, and the whole market seems to have grown steadier.

CENTRAL PENNSYLVANIA

Production for October totaled 82,714 cars as compared with 74,039 cars for September. The maximum daily production for the present year was reached on Oct. 30, when 4,023 cars were loaded. On the following day it dropped to 3,104 cars and on Nov. 1, it dropped to 2,383. The drop was due to the car shortage, although some little improvement is noted.

Since the fatal disaster at Spangler on Nov. 6, production fell off, particularly in Cambria County, due to the miners helping in the rescue work at the Reilly mine and the concentration of fire and mine foremen at that point.

FAIRMONT

Car shortage is still interfering with production. The car supply on the Western Maryland is somewhat better than on the B. & O. Lake shipments have been appreciably increased. Prices for Eastern delivery are not on quite so high a level.

NEW YORK

If producers booked one-half the orders represented by the inquiries received the mines would not be able to produce the coal needed to meet the demand. This was the opinion of some local houses, while others contended there was little doing. The number of cars at the local docks were about the same as last week.

Buyers are apparently on strike. It is believed they are waiting for the close of Lake navigation. With this source of consumption cut off they believe larger shipments will come to this market, increasing supplies and probably lowering prices.

An embargo was reported as having been placed on Monongahela coals coming east. This action was taken in order to force the shipments of these coals westward.

The car shortage is becoming more acute. None of the roads can boast of more than 50 per cent normal supply while most of them are running from 10 to 20 per cent below.

Lake demand is stronger than Tidewater. Considerable Pennsylvania coal is going into New England with the result that the Southern coals are losing some of the market obtained during the strike.

British coal arrives in small quantities now. There is some in the harbor but buyers do not appear to take kindly to it. Welsh anthracite is being offered to consumers at around $15. Southern coals are not active here. Quotations were around $9 toward the end of the week.

UPPER POTOMAC

The advent of November found mines producing more coal on an average than during the year 1921. It is true that there is not a large tonnage being mined in some parts of the Georges Creek region but on the Cumberland Division of the B. & O. the output is increasing and in the Upper Potomac field it is larger than at any time in recent months. Market conditions are largely unchanged. The best demand was from the West.

BALTIMORE

The fact that Federal Fuel Distributor Spens announced from Washington that there was now approximately 35,000,000 tons of soft coal in storage has had a tendency to make fuel burners in Baltimore feel firm in their position of refusing to buy largely for storage. While Baltimore industries have been buying lightly and a review of the storage situation shows that there is not more than about a 40-day supply ahead, the situation as to demand and run of coal to this point is such as to leave a market without exciting features.

While most of the best grades of steam are under contract, there are some on the market and the offerings of intermediate and lower grade coals have been so free as to throw the trading into active competition. A renewed activity is noted on the coastwise movement. For the first ten days of November four steamers cleared with coal, two of the New England Fuel & Transportation Co. for Boston; one of the Munson Steamship Line for Portland, Me., and one for Searsport, Me. No further importation of English coal is noted, nor was there any shipment of American coal on export.

South

BIRMINGHAM

The cry for domestic coal continues to feature the trade here, with little or no improvement in supply. A survey of local yards recently revealed a total of approximately 15,000 tons on hand, which would last scarcely ten days in the event of a cool spell. The slack supply of domestic is due to two causes—shortage of cars and lack of demand for steam coal in such volume as should exist at this season of the year.

The commercial market is without change. Demand is comparatively light and there is some surplus of the low-grade coals. Commercial mines are operating from one-third to half time. Quotations have undergone no change in the past week.

Car supply is scarcely better than 50 per cent in the field, but the railroad shops are making better headway in repairing equipment and restoring it to service. The situation is expected to improve gradually.

VIRGINIA

Production has undergone a slight decrease, due largely to the loading slump on the Southern and the Interstate, offset in part by increased production on the N. & W. and the C. C. & O. Losses are due entirely to a shortage of cars and other transportation difficulties. Despite lack of briskness in the market, the entire output is being readily absorbed, though prices are low, the range on mine run being $3.50@$4.50, depending upon the market in which coal is sold.

Anthracite

Householder Loath to Order Anything but Anthracite

Substitutes Urged as Shortage Becomes More Evident—Pea and Buckwheat Moving More Freely — Producers Aided by Mild Weather in Effort to Satisfy Needs of Northwest.

Substitutes are being urged on consumers as the shortage becomes more apparent, but householders are still loath to buy anything but anthracite. The strong demand, however, is enhancing pea and buckwheat is also moving more freely. Producers are making every effort to supply the Northwest before Lake navigation ceases, which may account for diminishing receipts in the East. In this they are abetted by the mild weather, which has cut down the season's shortage, estimated earlier in the year at 40 per cent. Lake dumpings at Buffalo were 99,000 tons last week, as compared with 94,200 tons in the preceding week.

The smaller steam sizes are still a drug on the market. Steam coals are in distress at New York Tidewater and some barley in loaded boats has gone for the freight charges.

PHILADELPHIA

The week has been almost completely barren of shipments. Outside of fair independent receipts it can be taken almost literally that the companies have shipped no coal at all. The yard with coal is the exception now, even those large yards which have rarely ever been without stocks.

The public is surely favored by the weather, and it is just possible that the big producers are watching this phase, being ready to divert coal here the moment that normal November weather may arrive. The report is strongly current that the heavy shipments to the Northwest are being made by direction of the Federal Fuel Administration.

The dealers here argue if conditions are so severe there, they should use bituminous coal, which can be supplied to that district much easier than anthracite.

The best news the retailers have is a promise that a break in the shortage of coal here is to come soon. A few already advise they now have the first reports of shipments for weeks. The tip has been passed that by Nov. 20 coal will begin to roll along in better volume. So far the public is fairly calm over the situation, as very little fuel is needed, but despite this the retailers report that they are continually urged to make deliveries as soon as possible.

Steam coals are still lagging behind with a bit more improvement in buckwheat. Much of this improvement though is being made at the urging of producers who insist that some buckwheat must go with family sizes.

BALTIMORE

Anthracite dealers are having a most difficult time in attempting to meet even the most urgent demands of customers. It is estimated that, despite recent arrivals at the rate of more than 2,000 tons of hard coal daily, that there are still more than 40,000 homes not supplied with coal, of which probably 25,000 at least would have had a large part of their winter supply in by this time. There are also a large number of consumers using up to one- and two-ton deliveries which were made to them on account. Many dealers have not gotten around their customers even with the one- and two-ton deliveries. Fortunately the weather has been mild so far, but consumption has been heavy enough to cause quite a few consumers to start a call for additional fuel.

BUFFALO

The demand of course greatly exceeds the supply, but the weather has been so mild that nobody is very urgent, especially as the supply of natural gas keeps up well. Quite a good many have bought coke, soft coal or small sizes of anthracite and there certainly will be no distress right away, if at all.

Complaint is made that Buffalo has not received as much coal as was allotted to it. Still the shippers are predicting that there will be little or no difficulty. The independent operators are turning out only a small amount of coal, as they find it hard to get cars. They are still asking $12.50@$13 for it at the mines.

Lake shipments are not up to the average of former seasons, being for last week 99,000 tons, of which 41,200 tons cleared for Duluth and Superior, 9,200 tons for Ashland, 7,800 tons for Hancock, 25,500 tons for Milwaukee, 9,300 tons for Sheboygan, and 8,000 tons for Chicago. Rates are unchanged.

NEW YORK

Pressure is being used to induce users of the domestic sizes to revert to substitutes. So far these efforts have not been entirely successful but greater success is looked for as the winter advances.

The one thing that has prevented a serious situation has been the mild temperatures. Those consumers who have not yet obtained any coal are becoming alarmed lest they will have to be without furnace heat for some time to come. Retail dealers' books contain many orders which have not been filled, although the orders were entered some time ago.

Because of the scarcity of the larger sizes dealers are able to move more pea coal, and this is moving well for this market.

The steam sizes continue to move slowly. Buckwheat is the exception. This size is being taken by some dealers when they obtain the larger coals at the mine. Greater difficulty is experienced, however, when efforts are made to move the coal already at Tidewater and it was reported that some loaded cargoes had been offered as low as $5, alongside.

There is practically no call for rice and in many instances buyers have been able to name their own price. Barley is dormant. It was said that some of this size had been sold in loaded boats for the freight charges.

BOSTON

Shipments are coming along with exasperating slowness. By water there is delay in loading, and all-rail there is shortage of cars and locomotives. The producing companies, who are making a big effort to get coal to the Lakes before the close of navigation, are curtailing their shipments to New England and other sections. As a result, there is a lot of apprehension lest really cold weather overtake the volume of coal normally due this territory.

At retail there is constant pressure on the part of householders. The largest Boston distributor has at last advanced its retail price to $16, the mark set by most of the other dealers a fortnight ago.

West

SALT LAKE CITY

The car situation in Utah is still a troublesome problem. The carriers appear helpless to effect any noticeable increase in the slim supply of cars delivered to mines.

The recent cold snap continues, setting up in Salt Lake City exactly the condition which is expected to arise in every other market with the first real cold. The supply is low, people are beginning to scramble for fuel, and the tendency toward higher prices is difficult to restrain. However, the recent indictments of coal men is having a good moral effect on some of the less responsible ones. There is considerable worry in certain quarters over the danger of some people suffering soon for want of fuel.

Canada

TORONTO

Supplies of anthracite coming forward are not sufficient to fill all orders for the late and dealers are obliged to refuse further orders until those in arrears are filled. The standard price of $11.50 per ton is maintained by the larger dealers, but some of the others who are unable to secure immediate delivery from the mines and obtain supplies through brokers ask as high as $18. Little change is reported until navigation closes and some of the coal now going west by water is diverted to Ontario points.

Conditions as regards bituminous show little change. Supplies being rather more plentiful, but prices variable. Lump is carried into sellings for $8.75 and upward, and Pennsylvania soft coal at about $8.

Chicago and Midwest

Dull Trading Shows Few Signs of Improvement Yet

Yields All Thankful for Short Supply of Cars—Lump Prices Fairly Firm but Steam Sizes All Drag Bottom—"Oh for Winter!" Sighs Trade.

Demand is practically everything continues light with only one real prospect of relief—imminent winter. A thin trickle of steam demand which is keeping itself out of public sight is the only change worthy of mention since last week. This is so trivial as not to have lifted screenings out of the price dumps, but it indicates some buying must be done soon. Markets generally remain so lifeless that the producing fields can not but be thankful that car supply continues weak.

At St. Louis, market conditions remain as low as last week, with not a single sign of relief. Kentucky fields are glad they are averaging but 18 to 20 per cent car supply and are wondering whether they will lose even more of their market when the Lake shipping season closes. In all fields, business is largely on a day-to-day basis and price concessions on everything are made frequently.

ST. LOUIS

Continued warm weather has also ruined the local market. Domestic buying has practically stopped and steam users are playing the market for further reduction. Such coal as is moving to the dealers is being stored. There is nothing being stored in the way of steam locally, except by the Union Electric and Laclede Gas companies. The country demand for steam has suddenly dropped off on account of warm weather and the effort made by shippers to move a little has reduced prices. This has become a continuous performance.

Country domestic has mixed up and very little is moving. The entire Middle West hopes for and expects a reduction in prices, while operators are steadfast in their refusal to make any concessions. The Terminal congestion in St. Louis is bad as ever though there has been a little relief. Nothing comes in from the Arkansas district.

LOUISVILLE

Due to the fact that eastern Kentucky is not averaging much better than 18 per cent car supply production is at a standstill. Quiet conditions prevail on the Lakes, however, as the market is so small that the operators are able to maintain prices in spite of the fact that West Virginia is quoting lower figures. However, if the Lake movement does not last much after Nov. 15, it is believed that prices will break somewhat, especially as cessation of Lake shipping will perhaps result in more short hauls and better car supply.

Right now there is reported fair movement to Ohio points, to Detroit, and to the railroads, while Southern business to the textile districts has not been so keen.

It is claimed by operators and jobbers that some of the market quotations on southeastern Kentucky are being confused with non-gas coal, and that sizes are not being properly differentiated. Some of the mines are producing a 2-in lump which is selling for $6@$6.50, while they are asking $6.50@$7.25 for 4-in. block coal. Harlan gas is generally quoted at $4.25@$4.50 for mine run, whereas non-gas coal is $4@$4.25 and some is reported at $3.75. Screenings are generally selling at about the mine run price, although some quotations have been reported as low as $3.50. While talk is being heard of $3.75 mine run, jobbers say that they cannot get coal in sufficient quantities to supply open orders at $4.

SOUTHERN ILLINOIS

Warm weather and an indifferent public that still continues to expect a lower price have almost stopped the demand for high-grade coal. Lump and egg continues to move, but is not in any great demand. Nut is heavy and screenings are a serious problem. The day, however, has been saved by the car shortage. The railroad tonnage is below normal, principally on account of movement and no empties.

There is no market for Duquoin and Jackson county coal. Even the screened sizes in some of these districts have to be forced. The Mt. Olive field has carried no-bills of lump, egg, nut and screenings for several days and Saturday night saw about 150 no-bills on the Wabash alone. Part of the trouble in this territory is the hopper bottom cars which dealers are refusing to accept. Both steam and domestic are topheavy, although the prices on the domestic sizes have been maintained, but screenings are breaking, as well as steam nut.

In the Standard field mines get from one to three days a week. The L. & N. has perhaps the poorest supply of cars. This week the Wabash had a surplus one day on account of every mine on its rail having no-bills and this surplus was diverted to the L. & N. for loading. The market for this field has gone to pieces. Screenings are still $1.25, 2-in. lump, $3, 6-in. lump, $4, and steam, nut and egg, $2.25 and up.

CHICAGO

Trade seems ready to show an upward trend at any moment with the arrival of a colder wave, but throughout the week business remained sluggish, with wavering of prices which were already weak. The determination of southern Illinois and Indiana producers to prevent any general decline on lump continues uniformly successful. The $5.50 level rules the market on very best coal. There are concessions here and there but not enough to start a general cave in. Screenings remain an absolute drug in all fields. Many no-bills of this size are held overnight in almost all fields, it is reported.

Trading remains light in all coals. The demand for anthracite is considerable but not ravenous because winter has not arrived and because many a consumer apparently has decided he is going to burn soft coal and will buy in a little when the price drops. Cold will attend to prices.

Only one report in the market is encouraging. The news is circulating steadily that a number of the bigger buyers are at last beginning to take just a little more coal than they use from day to day. The increase in volume is small and purchases are covered up as neatly as possible. This movement by no means takes care of the volume of steam coal available but it counts for something.

WESTERN KENTUCKY

Operators selling their production on a day-to-day basis have been forced at times to release unsold coal in the late afternoon at slightly under the market, with the result that some of this cheaper spot stuff, which is twin brother to distress coal, is being confused in quotations as the regular market.

Some of the jobbers who have had some open orders at $2.50 a ton, have had trouble in locating much coal that could be sold at that price for mine run, and still allow them a commission, although there has been some talk of $2.25 mine run, and perhaps some low-grade stuff has sold that low, other than loaded coal that the operator had to dispose of. However, really first-class mine run is fairly firm at $2.50@$2.75 in quantities, as production can't be very active when car supply for the first several days of November has been but 25 per cent on the L. & N. and 30 per cent on the I. C.

The field in which western Kentucky coal is moving, has been materially reduced since mines north of the Ohio got back into operation. Movement by river has been very small also, due to continued low water in the Ohio.

Screenings have been weak in spite of comparatively small production, ranging $1.50@$2 for both pea and slack and nut and slack, while the pea and slack may be shaded by 10c. a ton. Lump is generally quoted at $4.75, with very little coal at under $4.75.

INDIANAPOLIS

Sunshine and balmy weather is a combination which promises to break prices on domestic coal. Steam prices have already softened, due to lack of demand.

The situation is without parallel in Hoosier mine operation. For five months the strike shut off much of the coal supply. Weeks have gone by since and yet there is no demand. Approximately half the mines are closed each day, either because of lack of cars or lack of demand.

Eastern Inland

Filling of Current Needs Leaves No Surplus Coal

Movement to Lakes Reduces Available Spot Commercial Fuel—Curtailed Supply and Increasing Needs Have Bracing Effect—Domestic Mine Price Up 50c. in Ohio.

Current needs are being met easily but there is no surplus left. Concentration of tonnage to the Lakes leaves little spot commercial coal available. The lack of abundant supply has firmed spot prices while the growing needs of consumers have had a strengthening tendency. Shipments to the Lakes probably will cease on Nov. 20, when, it is estimated, sufficient tonnage will be rolling to supply cargoes during the balance of the season.

The Ohio fuel authorities have raised domestic mine prices 50c. to safeguard home needs and prevent so much of this tonnage going to outside markets where prices are higher.

PITTSBURGH

Car supplies show no material change, running generally at about 40 per cent of rated mine capacity. Operators are maintaining contract shipments without much difficulty and have sold free coal for the open market, not enough to cause a decline in prices even though the demand is not particularly heavy.

The steel industry seems to be able to maintain its supplies of coal for gas, power and byproduct coking without much difficulty, and even to accumulate a little reserve. Steel production in October was at the highest rate since October, 1920. Demand for domestic coal is fair but not excessive.

Prices are a shade stiffer, although there is no important change in the quotable market. Fair grades of steam are $3.25@$3.50, ordinary byproduct, $3.75@$4.00, while high grade byproduct, may command up to $4.25. Youghiogheny gas is $4.50 for mine run, screened being $5@$5.50. Domestic 14-in. is $4.50, in accordance with the recent arrangement between the fuel administration and operators of the district.

CLEVELAND

The supply in this city is making no appreciable gains despite the recent agreement between the fuel administration and Ohio coal operators, who were to get more cars in return for consigning more coal to points within the state. At the present time the bituminous coal trade is concentrating upon shipments to lower ports.

The Lake movement has outrun expectations. It is now thought that fully 17,500,000 tons will be shipped. This will be about 5,000,000 tons short of the normal movement. It will be sufficient to supply current needs, however, but will not permit of a large carry-over next spring. Under an order from the I. C. C. all mines shipping to the Lake are guaranteed a 50 per cent car supply. A 48-hour priority also put all open-top cars into coal service for delivery of coal to the ports.

Partly as a result of the lack of abundant supply and partly because of growing needs of consumers, the Cleveland coal market continues steady. There has been no further increase in price during the past week, however.

The demand for household coal continues to expand. Dealers report they are from five to six weeks behind on deliveries. Pocahontas lump is quoted at $12.34. Hard coal is coming in a little more freely. No price is quoted, the customer being billed the price at the time of delivery.

NORTHERN PANHANDLE

Since the opening of the B. & O. to Western shipments production is on a little larger scale. There is a fairly large movement to the Lakes, with the price ranging $3.25@$3.75. The demand for prepared grades is somewhat stronger. River shipments also have been increased somewhat. Buying by steel and iron mills on a large scale is also stimulating production.

DETROIT

Buyers are still looking forward expectantly to some miraculous development to provide them with coal at a lower cost. Buying is apparently being limited to orders required to provide for current consumption, while the matter of accumulating reserves is set forward.

Jobbers are of the opinion that for a few days after the closing of navigation on the Lakes there may be a more liberal supply.

Hocking lump is quoted $5.75, egg, $5.25, mine run, $3.75, nut, pea and slack, $3.25. Three-quarter lump from Pittsburgh No. 8 is offered at $4.75, mine run, $3.75, slack $3.25. Fairmount lump is $4.75, mine run, $3.50@$3.75, slack, $3.25. Kentucky and West Virginia lump is $6.50, mine run, $4, slack, $3.75@$4. Very little smokeless coal is reaching Detroit.

BUFFALO

Consumers say they are getting more coal than they need and they believe that the worst of the car shortage is over. That cars will not be in full supply for a considerable time yet is understood by everybody, but it is not now believed by the great part of the trade that anything short of a big snow blockade will cut out the supply.

The roads differ much in their car supply. Some of them are about as short as ever, while some are reported to have 100 per cent. Taken as a whole the shortage is not as menacing as it was and if it lets up much more the predictions now made that prices will go to $2.50 may be realized.

Quotations are: $5@$5.25 for gas lump, $5.25@$4.50 for steam lump; $3.50@$3.75 for mine run, with Allegheny Valley something less on account of lower freight rate; $3.25@$3.50 for slack.

COLUMBUS

With the weather rather mild and with the demand for domestic as well as steam grades somewhat saturated, there is a slight weakening in the Ohio coal trade. This is not sufficient to cause any demoralization, however, and will probably be lost at the first cold snap. Prices on certain grades have declined although prepared sizes are still at high levels.

No change has been made in prices fixed by the Ohio Fuel Administrator. The conference called in Columbus ten days ago relative to shipping Ohio-mined coal to Ohio users has not done much to relieve the situation. Retailers are buying both West Virginia and Kentucky grades and are finding a sale at rather high levels.

Steam trade is rather quiet. Reserves in many instances have been built up and users are not showing much anxiety over the future.

The Lake season is nearing its end. The trade has been fairly good although a reduced tonnage was shipped to the Northwest.

EASTERN OHIO

Operations continue at a minimum because of car shortage or transportation disability. During the week ended Nov. 4 this district produced 296,000 tons or only about 48 per cent of capacity. Cumulative figures indicate a production of 8,787,000 tons or about 35 per cent of capacity for the year.

Demand for current needs continues strong because the quantity of coal available in the open market is inadequate. Little storing is yet being done by consumers, and the majority are awaiting the close of Lake navigation. It is understood that the shipping of coal to the lower ports will be shut off Nov. 20.

Retailers are facing an active demand and are besieging operators to furnish them with lump sizes. An announcement of unusual interest was made by the Ohio Fuel Administration allowing the additional per ton above the previous maximum price on lump, effective Nov. 15, for domestic consumption. It is claimed this will have the effect of greater production in lump coal for Ohio consumers and will also curtail the shipping of Ohio mined lump to consignees outside the state who were offering and were willing to pay higher prices. Spot prices show little or no change from those quoted last week.

Bituminous coal receipts at Cleveland continue at a higher volume than at any time this year. Arrivals during the week ended Nov. 4 aggregated 1,347 cars. Divided, 1,241 cars for industries and 106 cars for retail yards. This is a decrease of 300 cars under the preceding week.

In the Lake trade the Ore & Coal Exchange figures indicate that up to Nov. 6, 14,967,844 tons have been taken by the fleet as compared with 21,254,280 tons during the same period last year.

Northwest

Apathy Continues With Northwest's Warm Weather

Hard Coal Still in Keen Demand in Face of Small Supply But No User of Soft Coal Is Worrying—Prices Stable

Warmth still prevails throughout the region around the Upper Lakes. It seems to be sufficient to keep bituminous coal in a sluggish condition. Very little stocking is going on and trade shows a decided need for a cold snap. Coal men are fretting a little about the distributing problems that will arise with the first icy wind sweeping out of the North. The only sign of life anywhere in the region is a little railroad buying down around Milwaukee.

Anthracite remains in keen demand with the supply as short as it was a week ago. Deliveries by rail are counted on to finish out the winter shortage. Some coal in rail that was tied up near the fields was reported to Fuel Distributor Spens and better deliveries have been promised. Prices generally throughout the Northwest remain stable.

DULUTH

General stiffening of the market is noticeable here this week and the anthracite market is also strong, although the increased levels quoted last week are not evident. The hard coal that was sold at an advance was some which came from mines which were outside of the general maximum price agreement and for this reason a higher price could be asked.

Official figures of shipments from the docks for October show that 10,317 cars went out. This compares with 16,178 cars in September of this year and 19,727 cars in October last year. Shipments were better than reports from private dock operators seem to indicate throughout the month and would have been better still if more cars had been available.

Receipts for the year at Duluth-Superior harbor are placed at 3,710,697 tons, which includes 1,664,193 tons of soft coal, 222,824 tons of hard coal and 11,672 tons of anthracite pennsylvania, which have been shipped here from Fort William, Ont., for transshipping purposes. Last year to Nov. 1 3,240,284 tons had been received, of which 1,968,464 tons was bituminous and 1,271,820 was anthracite. Receipts for October were approximately one-third of the total receipts for the season, 1,242,563 tons bituminous, 211,441 tons anthracite and 4,228 tons anthracite pennsylvania.

One more trip is as good as another's on the date of the closing of navigation, and whether that date is early or late depends whether there will be plenty of coal or just enough to go 'round. It is planned to lay up as many boats as possible at this port.

MINNEAPOLIS

Until there is a decided touch of cold weather, there will be no real activity in the coal movement. Consumers are still hoping for further reductions in prices. And it must be admitted that the successes which have attended their efforts thus far would seem to justify their hopes. Today steam coals of the different grades are selling at not over 50c. above the price of a year ago.

Conditions so far seem to extend a special dispensation of favor to the Northwest in the matter of fuel. Receipts of coal on the docks on Lake Superior have been about 40 per cent of those of last year, with hard coal only about 16 per cent of last year. Yet in the face of such an apparent shortage, the demand has been slack enough to force reduced prices right along on all soft coal. Hard coal is in a class by itself, when it comes to prices.

On the other hand, if cold weather shall prevail, as it may do at any time now, it would seem as though it would bring about an immediate scarcity of supply. For the retail trade has not been stocking soft coal to any extent, and has been unable to get much hard coal. The apparently sufficient stock of soft coal, seeming large in mild weather, will melt away very fast in zero days. So the problem now is wholly one of weather.

MILWAUKEE

The coal market remains quiet under continued fine weather. There is little anxiety in regard to the winter fuel supply, now that it is certain that there will be ample stock of soft coal. Anthracite is wanting, however, but dealers believe that railroads will be able to maintain a sufficient supply during the winter months. An appeal to Federal Fuel Administrator Spens released quite a number of cars bound for this market which had been stalled on sidetracks at Hazelton, Pa.

The shading in mine prices of Illinois and Indiana coal is not felt here. Only a sharp reduction of something like $1 per ton would force prices down here. Pittsburg, Hocking and Youghiogheny has been advanced 50c. per ton. Screened now sells for $10.25 wholesale and $11.75 retail. Pile run is wholesaled at $9.50. Pocahontas has also been raised 50c. per ton. Screened is now $13.75 wholesale and $15.25 retail, and mine run, $10.25@$11.75.

Cargo receipts by Lake thus far in November aggregate 41,500 tons of anthracite, and 88,738 tons of soft coal. If good weather prevails during the rest of the Lake period, the supply of both hard and soft coal will be greatly augmented.

New England

Little Change in Market; Inquiry Light and Scattered

Prices Show Tendency to Firmness—Large Plants Still Disinclined to Buy—Demand Uninfluenced by Car-Shortage Reports—Improvement Unlikely This Month.

The market shows no material change. Occasionally there are reports of better demand, but inquiry is still light and scattering. Both at the rehandling wharves and all-rail there is a slight firmness in price, but there has not yet been realized any price that would show more than a small advance over the market level of a week ago. The large corporations are still in comfortable position as to reserves and apparently there is no inclination to buy for the present.

Central Pennsylvania shippers are trying to impress upon regular customers the advantage of making purchases at present prices, but the most alarming reports of car shortage seem to have little influence upon current demand. The territory easily accessible to Tidewater is loaded up with British as well as Southern coals.

At Norfolk and Newport News there are still tonnages available far in excess of bottoms waiting, and while accumulations shift up and down from day to day there is still ample Navy standard coal offering at prices not much in excess of $7. Heavy movement West is followed almost regularly by embargoes that throw the bulk of current mining to Tidewater and the smokeless agencies are by no means relaxing their efforts to place coal in New England.

At the Philadelphia and New York piers there is still very little business on steam grades. Operators who are hardy enough to send coal down in the hope of making spot sales are almost uniformly disappointed and find themselves obliged to sacrifice.

Among retail distributors of anthracite there is developing a limited demand for screened bituminous of good grade, but in no section thus far is there any special interest in substitutes for hard coal. Not yet are consumers here convinced that they must take a leaf out of the Western book and use prepared sizes of bituminous. It is quite possible, however, that colder weather may have its influence on the market for these sizes.

Cincinnati Gateway

Bulk of Recent Activity Consists of Lake Business

Movement Improves Steadily—Domestic Buying of High-Volatile Coals an Encouraging Market Factor—Demand for Railway Fuel Quickens — Public Institutions Active.

Lake business handled through the Cincinnati coal offices has been closing with a rush, this forming the bulk of the activity here last week. The movement has been steadily improving and with the N. & W. placing its titanic cars in this trade the movement off that line has been accelerated. Domestic buying of high-volatile coals has been another bright spot, while the other points of activity have dropped down to a steady grind.

Demand for railway fuel has been picking up and some large buying orders are in sight for lines north of the Ohio River. Steel mill business is not so active and industrial plants have been less urgent in pressing their needs. Michigan and northern Ohio public institutions have been in the market stronger than for some time past.

HIGH-VOLATILE FIELDS

Kanawha

With the Western embargo lifted, mines in the Kanawha field are beginning to recover from the slump. Although it has been possible to increase production somewhat, it is still not much over 25 per cent owing to car shortage. There is a market for all the coal the field can produce, now that it is no longer necessary to ship the entire product of the region to the East.

Logan & Thacker

Logan mines have also been able to increase production slightly. Opening of Western markets stimulated the demand somewhat for Logan coal which had been diverted to the East for a time. Owing to the fact that production is so limited there is really little spot coal to be had.

Production in the Kenova-Thacker field is not fluctuating to any great extent. More coal is being produced proportionately in this district, however, than in other high-volatile fields owing to the fact that the N. & W. is somewhat better able to handle loads.

Northeastern Kentucky

Despite the effort of the general run of buyers to remain out of the market and "bear" prices, there is still a fairly brisk demand and little chance of prices declining any further. Much coal is going to the Lakes and some is also being marketed in Ohio.

CINCINNATI

With the Tidewater prices a shade better than they have been for some weeks past the N. & W. producers were inclined to look more keenly in that direction than to the Inland trade. Smokeless business, both from the Pocahontas and the New River districts, was holding around the $6 basis that had been established by Commissioner Spens, but the deliveries except to the Lakes were not as large as they might be.

Car reports at Cincinnati show that 1,682 less cars than the week previous had been sent back to the mines. Motive power on the C. & O. as well as on the L. & N. is in ticklish shape and the first flurry of winter is liable to spell an upturn to the prices. Southeastern Kentucky shows a slight increase in production with some mines working full two days a week. Logan County is offering more coal here than for some time past. This increase with other conditions has softened the market 25c. a ton in the past week.

Retailers found their prices cut 50c. this week by one independent company. Some of the others are holding to the old prices of the low level as follows: Smokeless lump, $10.50, run of mine, $8.75; splint lump, $10; slack, $7.50.

LOW-VOLATILE FIELDS

New River and The Gulf

New River producers are not making any progress in increasing their output owing to limited car supply, while better transportation conditions are still far from satisfactory. Inasmuch as the Western embargo was lifted about the first of the month, the region has a somewhat broader market. Mine run in the West has been bringing nearly as much as prepared grades in view of the price agreed upon for the latter. There is not a strong demand in the East.

In the Gulf region there has been a slight increase in production, which is now averaging a little over 100,000 tons a week, owing to improvement in transportation facilities. Virtually none of the coal is finding its way to Western markets. Although Tidewater demand is not active, nevertheless producers are finding a ready market for all the coal it is possible to produce.

Pocahontas and Tug River

Pocahontas production is on a somewhat lower level, a total of 231,000 tons only being the average within the last week or two. As only certain classes of equipment can be moved to Western markets, that is preventing mines from securing all the empties needed. The flow to Eastern markets is much larger than to points west of the Ohio River, notwithstanding the fact that there is a great disparity in the prices prevailing in the East and in the West.

Few Tug River mines are working more than two days during a week. Virtually all the product of this region, such as it is, is being marketed in Western points, with a fairly large volume moving to the Lakes.

Coke

UNIONTOWN

After having been in force for one day, an I. C. C. order directing 50 per cent of mine rating be shipped to the Great Lakes, the order was canceled as suddenly as it was issued. The ruling was made on Nov. 6 but did not get to railroads operating in the Connellsville region until Nov. 9.

The order was designed to get as much coal to the Northwest as possible before the Lakes closed, but operators here did not see the necessity of a mandatory order. They had found the Lakes trade a profitable market at a time when coal is not easy to sell and did not need a compulsory order.

Fairly large orders for railroad coal were placed this week but they in no way strengthened the market, which continues quotable at $3 for steam coal and $3.50 for byproduct. The car supply showed some improvement.

The coke situation is drawing most attention today because of the nearness of the furnace contracting period. The increased production is absorbed by the trade, but prices have not yet been stabilized.

CONNELLSVILLE

The coke market has experienced a sudden drop, practically overnight, about 50c. in furnace coke and $2 in foundry coke, the decline in foundry being chiefly by way of the unusually large spread over furnace coke being diminished.

At the same time that furnace coke prices declined a new alignment developed. Previously, the cheapest coke was spot coke, this being coke loaded and on railroad company track. It could be had at $7.50, while coke for regular shipment over a week or two commanded fully $8. There does not seem to be any distress coke now, yet coke for spot shipment is held at $7.25 @$7.50, while coke for shipment in a few days can be had at $7@$7.25. Foundry coke is now $8@$9, depending on brand.

Demand is rather light. Nearly all the furnaces now in blast that are dependent on purchased coke seem to be covered fairly well to the end of the year. Some Eastern blast furnaces now idle, are understood to have intimated that $6 would interest them, on the basis that they need to make pig iron at lower cost in order to make it salable. Operators, however, talk of weather troubles next month being likely to advance the market.

The *Courier* reports production during the week ended Nov. 4 at [illegible] tons by the furnace ovens and [illegible] tons by the merchant ovens, a total of 164,220 tons, an increase of 4,340 tons.

BUFFALO

Attention is turned mostly to the domestic supply. Prices have dropped steadily of late, being $[illegible] for 72-hr. Connellsville foundry, $7.50@$8 for 48-hr. furnace and $[illegible] for off-grades, adding $1.20 for freight. Some of the local byproduct ovens are selling stove for domestic use at $12

News Items From Field and Trade

ALABAMA

T. S. Ramsay, superintendent of the Tennessee at the Fruit Consolidated Coal Co., [illegible] Nos. 13 and 14 openings and the Clipper Mine, has resigned and will move to Bedford, N. C., where he has accepted a position as vice-president and general manager of the **Erskine Ramsay Coal Co.** **John Terry**, mine foreman at No. 13 mine, has also resigned and it is understood will be superintendent of the new operations of the Bedford company. **John H. Davidson** has been appointed to succeed Mr. Ramsay.

One of the largest coal mines in Alabama has been opened in Etowah County by the **Moffatt Coal Co.** of St. Louis. It is the Rising mine, which is producing between 250 and 300 tons a day and probably will reach 500 tons when it is fully developed. It is a slope mine with three passageways on the main slope at an angle of 45 degrees, one way is for mule, one for air and the third for haulage. This is the first venture of the Moffatt Coal Co. into the South.

CONNECTICUT

The Kimberly Coal Co., Inc., of New Haven, has been incorporated under the laws of Connecticut, to carry on a general coal business in that city. The firm will have a capital stock of $10,000. The incorporators are: Michael and Benjamin Krull, and Abraham Shalit, all of New Haven.

ILLINOIS

The Harrisburg Consolidated Coal Co., Chicago, has been incorporated to mine and sell coal by Thomas H. Cochran, William J. Brennan and C. W. Baltzer.

The Chicago Wilmington & Franklin Coal Co. announces the reopening of its mine 6, located near Herrin. The mine has been idle since Oct. 8, 1921.

Plans to make the Big Muddy River navigable to the Mississippi, making possible the trading of Franklin County's coal on barges to be towed to the Mississippi, are being considered. Such a move would be made to reduce the car shortage and would permit delivering of coal in Chicago and other points at $1 a ton cheaper than at present. It is believed **William Sackett**, state superintendent of waterways, will push it during the coming year and that it will be submitted at the next legislature with appropriations for undertaking the work. This is according to the plan of the reasons why the **Federal Illinois Power Co.** decided to develop at Grand Tower on the Mississippi rather than on the Big Muddy and won't coal barges can be handled.

Candidates for offices in the Illinois U. M. W. will be asked to file a statement showing [illegible] by failure of the report [illegible] not prepared. A report of the findings has been [illegible] to each of the local unions [illegible] with the recent [illegible] Australian [illegible] connected or prospective. Attention to the [illegible] report the fact that [illegible] **Frank Farrington**, the president, [illegible] a total of 351 [illegible] and a total of 112 for **John Hlad[illegible]**, who was [illegible] in the [illegible] Farrington and [illegible] Hladnesky and [illegible] Farrington [illegible] **Red Ring Coal & Mining Co.** with [illegible] at Red Ring, Ill. The [illegible] of the [illegible] and the [illegible] of Linn, and [illegible] A. Kimbel of St. Louis and [illegible] of Linn.

W. L. Walton of Chicago was in Williamson County mining fields recently visiting various mines near Marion. He is connected with the Lake & Export Coal Sales Corporation and on his return trip, visited the St. Louis offices of the company.

INDIANA

The Conveyors Corporation of America, Chicago, has appointed the **Geo. W. Fife Engineering Co.**, Indianapolis, its representative for the sale of American trolley carrier in the state.

Mayor John M. Grayson, of Vincennes, has announced he will **open a municipal coal yard.** Indiana mine run will be delivered in the basements of the domestic consumers at $5 a ton. Coal is to be procured from one of the largest mines in Knox County. Coal will not be sold in less than ten lots and must be paid for on delivery. Mine run is retailing there at $6 a ton. Members of the Vincennes Retail Coal Dealers' Association have protested against the opening of the yard.

The Peerless Coal Co., an Illinois corporation, has qualified to do business in Indiana. E. J. Suffel, of Indianapolis, has been named state agent.

Resolutions directed toward the **elimination of profiteering in coal through regulation of the assigning and distributing of cars at the mines**, were passed at a recent meeting of the directors of the Indiana State Chamber of Commerce. The need for the regulation of car distribution by federal and state boards was brought to the attention of the organization by its president. Copies of the resolution have been sent to the committee recently named by President Harding for investigation of the coal industry, as well as to the Public Service Commission of Indiana and all members and member bodies of the Indiana State Chamber of Commerce, representing more than 25,000 firms and individuals in the state.

The Jasonville Fourth Vein Coal Co., of Jasonville, and the **Busram Creek Coal Co.**, of Terre Haute, have filed final certificates of dissolution, while the **Bicknell Coal Sales Co.**, Indianapolis, has filed a preliminary certificate of dissolution with the secretary of state.

MARYLAND

Cumberland capitalists have organized the **Helen Coal Mining Co.**, the offices of which will be at Cumberland. This company has an authorized capital stock of $[illegible]. Chiefly interested in the new enterprise are Robert Grant, Sr., John F. [illegible], M. H. Grant, H. M. O'Brien and [illegible] R. Nesbitt, all of Cumberland.

MICHIGAN

And now Michigan enters the Ohio Fuel controversy. The Michigan fuel administrator has written to the Washington fuel administration protesting against any federal order which will hold Ohio coal within that state thereby preventing its normal flow into Michigan. The Ohio official's plan proposes a preferential treatment in the distribution of coal within Ohio zones to Ohio consumers but Ohio mine operators with [illegible] shipments of coal [illegible] rearrangement of cars [illegible] priority.

As a means of providing anthracite for [illegible] communities of the state which have been unable to obtain [illegible] the Michigan fuel administration [illegible] according to the state administration [illegible] that **purchase of a supply be made by the state** under authority contained in the [illegible] law, payment to [illegible] revolving fund [illegible] for fuel purposes. The [illegible] collected in the state [illegible] by the fuel administration [illegible] that have been [illegible] to the authorities.

In speeding up the applications received from the state's new [illegible] **Charles F. Dann**, fuel [illegible] for Wayne County is making [illegible] applicants who reported they had been in business about three weeks. His purpose is to guard against "snowbird" dealers taking advantage of the law.

NEW YORK

The newly organized **Morrow Callahan Coal Co.**, of Pittsburg, has opened an office at 1 Broadway, New York City, which will be headquarters for its pulp and paper mill department. **J. Floyd Massey** is manager of the department and others interested are **E. C. Woodruff** and **Wm. A. White.**

Victor T. Goggin and James H. Ripley, formerly contracting engineers of Dwight P. Robinson & Co., Inc., have formed under the name of **Goggin and Ripley, Inc.**, with headquarters at 350 Madison Ave., New York, a personal service corporation to assist business executives, bankers and engineers in conceiving, financing and developing construction projects.

The Simplex Wire & Cable Co., of Boston, has established a branch office in New York at 120 West 32nd St., with Joseph G. Brobeck as manager.

Before owners of buildings in New York City are permitted to **substitute fuel oil burning equipment for coal burners** they must conform to the stringent rules of the Fire Department and the Board of Standards and Appeals. So far fifty buildings have conformed to the rules and have been granted permits to substitute oil for coal. As many more applications are now in the hands of the authorities for action and some of the buildings are already equipped with the necessary apparatus awaiting action on the permits.

The twenty-fifth anniversary meeting of The Merchants' Association of New York, will be held in Madison Square Garden on the evening of Friday, Nov. 17.

The sixth annual industrial conference of the State of New York will be held in Buffalo, Nov. 21, 22 and 23, at the Lafayette Hotel. The central theme for the conference is to be **elimination of waste in industry.**

OHIO

Administrator Neal has secured the removal of priorities on West Virginia, Kentucky and Pennsylvania lump destined for Lake shipment. It was believed that the priorities would serve to further curtail the supply of coal cars in Ohio and would serve no beneficial purpose.

The Columbus municipal coal yard announces that no deliveries of coal will be made before Nov. 20, as all teams and apparatus are necessary for the street cleaning work previous to that date. Practically no coal is on hand at this time.

The Pfau Coal Co., Bolivar, has been chartered with a capital of $20,000 to mine and sell coal by C. J. Pfau, Hermine E. Pfau, William Daley, J. O. Peoples and H. L. Pfau.

The Speaks-Drais Coal Co., Columbus, chartered several weeks ago with a capital of $10,000, has taken over the retail coal business formerly operated under the name of the **S. S. Speaks Coal Co.** S. S. Speaks is president and Charles W. Drais, secretary and treasurer.

Ohio Administrator Neal is having an **extensive study of retail costs** in some of the larger cities in the state with a view of revising the list of retail margins allowed. Protests were made by retailers in Toledo, Cleveland, Columbus, Youngstown and Dayton. Expert accountants have been put on the books of certain retailers in the cities named and a new list will be announced as soon as the work is completed.

The complaint brought by the **Ohio Mining Co.**, and twenty-two other operators in the Hocking Valley field against the **Hocking Power Co., the Athens Electric Co. and the Southern Ohio Power Co.**, protesting rates charged for electrical power at their mines which has been pending in the Ohio Utilities Commission is still undecided but the commission has ruled that the last named concern was not a public utility and thus could not be brought within the jurisdiction of the commission. On this question the operators interested carried the case to the Ohio Supreme Court for a decision on that question. The Ohio Utilities Commission is still investigating the reasonableness of the rate and to that end has ordered an inventory of the assets of the two electrical companies.

The Lake Superior Coal Co., Cleveland, has been incorporated with a capital of $10,000 to mine and sell coal in Pittsburgh No. 8 field. Incorporators are W. F. Maurer, T. B. Belton, Norton McGriffin, John F. Wilson and E. R. Donlin.

The Salisbury Coal & Clay Co., Cleveland, has been incorporated with a capital of $400,000 to mine and sell coal as well as operate clay mines. The incorporators are: Joseph F. Rumsey, B. O. Young, Thomas H. Moore, Bess Allen and P. A. Berry.

Members of the Middletown city commission have decided not to establish a municipal coal yard owing to the uncertainties of the coal business and the expense necessary for such a venture. City Manager Kenyon Riddle had proposed the establishment of such a yard.

The stripping operation of the **Piney Fork Coal Co.**, at Piney Fork, Jefferson County, is now going full blast. **The Panhandle Collieries Co.**, another one of the **Hisylvania Coal Co.**, interests is also being operated and a good output is reported. The latter operation is comparatively new.

W. D. McKinney, secretary of the Southern Ohio Coal Exchange, is out with a statement to the effect that transportation difficulties are the handicap which is keeping the production of coal in all Ohio fields to a low point. He claims that this is partly due at least to the use of coal carrying equipment for other purposes other than the transportation of coal and asks everyone to keep an eye on the illegal use of coal cars.

The Caledonian Coal Co., has been chartered with an authorized capital of $50,000 to take over the Caledonian mine near New Lexington which has been operated as a partnership. The incorporators are James Williamson, George Williamson, E. M. Blower, Charles Wallace and John Williamson. Headquarters are in Columbus.

OKLAHOMA

D. K. Hutchcraft, formerly vice-president of the Indiana Air Pump Co. has been appointed district manager of the Chicago Pneumatic Tool Co.'s branch office recently established at Tulsa.

R. J. Danford, president of the **Walker Coal Co.**, is still occupied with the installation of electrical equipment in that company's two shaft mines near Vinito. These operations are at the extreme southwest corner of the big coal field. There is much development at that end of the field and the new coal mining town Banzet is doing a thriving business.

The Warden-Pullen Coal Co. is making its first shipment of coal from its new No. 2 mine, opened earlier in the year. Its No. 1 mine continues to put out its capacity, and it is reported that the mines in the Henryetta district, about 54 in all, are working full force.

PENNSYLVANIA

Four men lost their lives and four others were injured, one perhaps fatally, when a charge of dynamite, fired in some unknown manner hurled tons of rock upon them, in the Birdseye slope of the Olyphant mine of the **Hudson Coal Co.** on the mountainside beyond Throop last week.

The Pennsylvania State Employment Bureau estimates that at the beginning of November there was a common labor shortage of 25,000 to 35,000. The most serious shortage is in the Pittsburgh district. The bureau gives as the number of unemployed at the present time 37,880, while the number of persons out of employment because of strikes is 92,273. The coal strike in the Pittsburgh district, the employment bureau states, is responsible for 80,000 persons being out of work.

The Pennsylvania State Forestry Commission is distributing 4,000,000 trees for re-forestration purposes and the coal companies and water companies of the state lead in the number of trees allotted. The coal companies are planting additional land for the purpose of growing mine props and the water companies are planting trees for protection of their water sheds.

The Pine Hill Collieries Co. has notified the State Department at Harrisburg of an increase in capital stock from $5,600 to $3,000,000. Edwin S. Dixon, Jr., Philadelphia, is president of the company.

Fifteen hundred miners employed at the No. 14 colliery, **Pennsylvania Coal Co.** near Pittston, went on strike last week when forty-seven carpenters employed at the colliery refused to join the union or pay their "two days' pay assessment" which was ordered during the five months' suspension. Company officials contend that the carpenters are members of the carpenters' union and do not come under the jurisdiction of the U. M. W. The leaders of the miners express a different view, however, and say that all men working in or around the collieries are qualified and should belong to the union.

Investigators of coal deposits in Lancaster County are being made by mining experts for the purpose of determining the possible commercial value of the product. A survey of the hills in which small deposits have been found at various times was made recently by representatives of the federal and state mine departments.

The Bertha Coal Co. recently acquired one hundred new seventy-ton steel hopper cars from the Ralston Steel Car Co., which have been placed in service between its Bertha Mine, Dinsmore, and the various plants of the General Motors Corporation in and around Detroit, Motors Corporation having arranged for a long-term fuel contract with the Bertha company.

Coal mining companies in Cambria County have filed appeals with the county commissioners from the tri-ennial assessment on the grounds that the real estate was not assessed at the actual value thereof, being assessed without due regard to the valuation and assessment made of other similar properties in the country, but was assessed in excess of the value and assessment of such other properties. The following companies filed appeals: Holding of the **Wilmore Coal Co.**, Richland and Adams townships and Scalp Level borough and Conemaugh, Croyle and Stonycreek townships; **Berwind-White Coal Co.**, Richland and Adams townships and Scalp Level borough; **Maryland Coal Co.**, Richland, Croyle and Adams townships.

The general offices of the **Mon-Scott Fuel Co.** will hereafter be located in Pittsburgh. Offices have been established in the First National Bank Bldg. The Pittsburgh office will be in charge of W. H. Davis. The company will keep its offices in Morgantown, W. Va., for use as a branch and selling agency. Through the Pittsburgh office the products of the **Hess Coal & Coke Co., Shamrock Fuel Co., Bear Mountain Gas Coal Co.** and the **Winstead Coal Co.** will be handled. General offices of the company have been located at Morgantown since the company was formed about three years ago.

Citizens of the Borough of Taylor have requested Attorney General George E. Alter to suspend the provisions of the Kohler mine cave law so as to insure full time coal mining operations by mines at that town. **The Glen Alden mines** are the principal source of employment for the community. The company was ordered to suspend operation a year ago when its operations threatened a portion of Scranton and the Taylor citizens say the company will not begin at Taylor until assured of the suspension of the mine cave law. The Attorney General has no power to suspend laws.

Raymond K. Bowden, of Niles, Ohio, has been appointed instructor in metallurgy, for 1922-23, at Carnegie Institute of Technology, Pittsburgh. The Department of Metallurgy at Carnegie Tech was recently selected by the United States Naval Academy as its graduate school of metallurgy. Beginning this year, two officers from the Naval Academy have been assigned to take up advanced work in metallurgical subjects at the Pittsburgh institution.

A decision of importance to the shovel trade was recently rendered by the Circuit Court of Appeals for the Third Circuit in the case of **John S. Surbaugh and Pittsburgh Shovel Co. vs. Hubbard & Co.**, No. 2838 March term, 1922. The opinion found the Surbaugh patent in suit No. 1,212,582 to be valid and infringed as to all claims in suit. The litigation is conclusive as to the validity of the patent. Under the decision the manufacture and sale of three, two and three prong shovels is controlled by The Pittsburgh Shovel Co.

VIRGINIA

The Willard Sutherland Corporation after announcing the closing of its Norfolk office Nov. 1 has reconsidered and decided to continue the business here under the management of **Chester R. Koontz.**

WEST VIRGINIA

[illegible] applications for certificates as mine foremen and fire bosses were received recently at [illegible] under the direction of H. M. Lawson, Chief of the West Virginia Department of Mines assisted by Inspector J. F. White and four other district mine inspectors. The examination covered a wide range of subjects and was said to be very [illegible] a practical one. Examinations have also been held in other sections of the state from time to time during the summer.

Control into ownership a few weeks ago the **Boulder Coal Co.** has secured 155 acres of coal land adjacent to Indian Creek in the Monongalia County field and is planning to develop the tract so acquired at the earliest time practicable.

It is reported in coal circles in the Pocahontas region that **Henry Ford** has purchased the **Twin Branch property** of the **Dex-Cur Pocahontas Coal Co.** and has already taken over the control of the property so purchased. It will be recalled that Mr. Ford recently abandoned the operation of mines at Nuttallburg because he found they could not be successfully operated in competition with other mines in the same section. It has been understood for several weeks that Mr. Ford has been negotiating for the purchase of one of the largest undeveloped tracts in the Pocahontas area. This tract is in Tazewell County, Va.

The Midland Smokeless Coal Co. is the name of a new concern launched with a view to operating in the Greenbrier smokeless field, this company being capitalized at $50,000. Headquarters are to be at Rainelle. Leading figures in the new company are: L. E. McClung, B. M. Higginbotham of Rupert, Guy B. Montgomery and C. H. Thompson of Rainelle; Ernest Reynolds of Glasbow, Va.

Organization of the **Clay County Coal Co.** with a capital stock of $[illegible] presages the development of coal land in Clay County on a fairly large scale. Huntington people, for the most part, are interested in this company, but its general office will be at Clay. Interested in this concern are: A. D. Callihan, J. Frank Grimm, Morris Hansford, of Huntington, H. L. Nye and C. A. Parcell, of Clay.

Charleston capitalists have organized the **Alpine Coal Co.**, with a view to operating on a fairly large scale in southern West Virginia high-volatile territory. Headquarters are to be at Charleston. Actively identified with the new company are: W. E. Wright, E. L. Michie, S. G. Smith, Thos. W. Hill and Arthur B. Hayes, all of Charleston.

Further development of coal property in the Williamson field is promised by the organization of the **Waugh-Longley Coal Co.**, headquarters of which will be at Williamson. This company has a capital stock of $10,000 and interested in it are: C. E. Waugh, M. E. Waugh, R. O. Haines, Jr., all of Williamson, F. L. Longley and Ira Longley, of Bluefield.

The Talisman Coal Co. is the latest to enter the Monongalia field, this company just having been organized with a capital stock of $10,000. Offices are to be at Morgantown. Identified with the new enterprise are: Robert L. Brock, John A. Wade, John H. Gross, Charles G. Baker and E. S. Wade, all of Morgantown.

The Brown Coal Co. of [illegible] has purchased from **Cole Brothers**, of Morgantown, 104 acres of Pittsburgh coal in the Star Mountain section of Harrison County, the purchase price of $[illegible] being paid in cash. It is said [illegible] section has only been in the process of development during the last year or two and is still to a great extent a virgin field. The purchasers are making preparations to drive an opening immediately and to erect a modern plant on the property. The Brothers were the contractors who built a line of railroad about seven miles from the Star Mountain field to the Main branch of the B. & O. which serves the Simpson Creek field.

Having sold coals to the amount of [illegible] to the Union Trust Co., of Clarksburg, the **Fairmont & Cleveland Coal Co.** will not only extend its business but will enlarge the Chesapeake plant at Barrackville recently purchased from the Chesapeake Coal Co. by the Fairmont-Clarksburg Coal Co. The purchase [illegible] the company of 2,000 feet in [illegible]. It is stated by [illegible] the capacity of the Chesapeake mine to 2,000 tons a day.

CANADA

The Scotia coal production [illegible] compared [illegible] corresponding [illegible] 1921 [illegible] 1,000 tons [illegible] 18,000 tons [illegible] the [illegible] and the output [illegible] 1922 [illegible] loss of [illegible] current [illegible] month.

Work [illegible] to be a coal mine of some **importance** [illegible] **Joseph Walker** [illegible] the town of [illegible] development [illegible] on the [illegible] of the seam [illegible] the day when [illegible] age [illegible] and [illegible] coal [illegible] to the Kettle Creek [illegible] a good [illegible] from [illegible] mine [illegible] the Nordegg Mine.

WASHINGTON, D. C.

The most extensive development of a **good road areas of certain Western states** [illegible]

One finished the cost of the **byproduct coke production** of the country as reported to the **reports being furnished the U. S. Geological Survey.** All producing companies are making monthly returns. The Survey's record of the monthly output of byproduct coke is complete for 1917 and 1918 and for 1922 and 1923, but the figures were not compiled during 1919 and 1921. In order to fill that gap in the statistical record of the industry, schedules have been sent by the Geological Survey to the producing companies on which they are asked to submit the production figures for those years.

Sales of explosives during September [illegible] 387. A permissible explosive is an explosive which is similar in all respects to the sample which has passed certain tests prescribed by the Bureau of Mines to determine its safety for use in gaseous dusty coal mines, and when used in accordance with the conditions prescribed by the bureau. While permissible explosives are designed especially for use in gaseous and dusty coal mines, they are suitable for use in other coal mines and for many other blasting operations. Serial 2402 may be obtained from the Bureau of Mines, Washington.

The issuance of Bulletin 167, **Coal-dust explosion tests in the experimental mine 1913 to 1918,** by George S. Rice, L. M. James, W. L. Egy and H. P. Greenwald, is announced by the United States Bureau of Mines. This bulletin describes the second series of coal-dust explosion tests conducted by the Bureau of Mines in its experimental mine. It covers a period of more or less consecutive testing, during which many important conclusions were drawn regarding the way a coal-dust explosion may originate, the mechanism of an explosion, and the methods of preventing explosions and of limiting incipient explosions.

Owing to the expense involved in publication, the entire distribution has been entrusted to the Superintendent of Documents, Washington, D. C., who sells the report at a price of $1.

A little **booklet entitled "War Surplus,"** [illegible] issued by the sales promotion section of the office of the director of sales, of the War Department. This booklet explains in a general way the methods of sale resorted to by the War Department in the disposal of its vast stocks of surplus property, and tells what these stocks consist. A loose leaf insert lists the more important sales scheduled for the near future with information as to where the sale is to be held.

Fact-finding with regard to wages and earnings of mine workers will be done by **Prof. Joseph S. Willitts,** of the University of Pennsylvania for the President's coal commission. Prof. Willitts is an economist of established reputation, who has done successful work in connection with wage scales. Since the Commission has committed itself to await suggestions from the various branches of the coal business before formulating its own plan of action no great amount of progress has been made during the past week in the formulation of its plans. The week has been spent, however, in informal conferences and consideration of the data which its staff already is laying before it. A plan is being worked out whereby all material submitted by outside sources will be carefully checked so that the commission will be in a position to underwrite any of the facts and figures which it may care to use.

Tests conducted at the experimental mine of the Bureau of Mines at Bruceton, Pa., hold out the hope that wireless waves may be used in the future **as a means of effective communication** between rescuers on the surface and miners entombed in mines following fires and explosions. These preliminary experiments of the bureau, made in co-operation with the Westinghouse Electric & Manufacturing Co., while failing to develop any practical method of using wireless waves for underground communication, nevertheless indicate clearly that electromagnetic waves may be made to travel through solid strata. In the Bruceton experiments, signals were heard distinctly through 50 ft. of coal strata, although the audibility fell off rapidly as this distance was increased. The absorption or loss of intensity with distance is very great for the short wave lengths used in these tests. Details of these experiments are given in Serial 2407, "Experiments in underground signalling with radio sets," copies of which may be obtained from the Bureau of Mines, Washington.

Federal Fuel Control Notes

The fifteen naval officers designated to act as field representatives of the Federal Fuel Distributor in as many districts into which the territory east of the Mississippi River has been divided for administrative purposes in connection with the present coal emergency, have resumed their duties at their respective posts, following a conference with Federal Fuel Distributor Spens in Washington, Nov. 6. The car supply situation, especially as it affects the Southern railroads, complaints of which were regarding the **failure of connecting lines to return coal-carrying equipment.** This particular situation, however, seemed to be improving. Use of other equipment, especially for the transportation of grain, sugar and other building material was reported and it was stated that the situation of coal cars was being investigated by the Federal Fuel Distributor. In general practice for the movement of coal have been almost entirely eliminated. The co-operation of coal operators with the government's coal representatives was [illegible] Conferences on the matter of prices will probably be held by the Federal Fuel Distributor in Washington in a few days with representatives of the operators from the coal districts. Operators from Kentucky fields and the Kanawha and Logan fields of West Virginia.

Operators from the Kanawha field discussed the price situation with representatives from Washington on Nov. 14. The operators expressed a unanimous desire to reduce prices but insisted it must be accomplished when their costs are being increased by a [illegible] mining costs are not increased, can work.

A party of Virginian Railway officials and members of the board of directors visited the Winding Gulf Field of West Virginia about the middle of November and held an extended conference with President E. E. White of the Winding Gulf Operators' Association. The potentialities of the Virginian territory were fully gone into and it was clearly shown in the conference that the coal tonnage in the section traversed by this railroad had been barely scratched. There is a feeling among operators that in the near future further appropriations covering the purchase of additional equipment for the needs of the Virginian will be forthcoming.

Publications Received

[illegible] Mines and the Purposes of Coal Utilization in the Fiscal Years 1916 to 1924, inc., a Preliminary of a Series of Coal Economic Papers, U. S. Bureau of Mines, Washington, D. C. (Technical Paper 333. Pp. 30. Illus.)

Operating Values and Rates, With Special Reference to the Utilization and Preservation of the Atlantic Seaboard, by Wilbur J. [illegible], Bureau of Mines, Washington, D. C. (Technical Paper 333. Pp. 30. Illus.)

[illegible] regarding operations, tonnages and charges in the permissible list of explosives [illegible] Bureau of Mines, Washington, D. C. (Serial 2402. Pp. 3.)

Traffic News

Not only is the sale of the **Morgantown & Wheeling,** a short coal-carrying road in Monongalia County opposed, but a special judge in the county court has entered an order [illegible] upon **Samuel Pursglove,** well-known coal man and receiver of the road, to secure the stock certificates of the **Monongahela & Ohio,** which are said to be in the possession of the **People's Natural Gas Co.** These stock certificates are said to be the property of the Morgantown & Wheeling [illegible]. It is contended that the stock certificates were never issued by the gas company although voted by that company in voting directors and in voting a mortgage of $[illegible]. Counsel for the M. & W. claim that the sale was unlawful and illegal, part of the road is objected on the ground that when the road became insolvent and was taken over by a receiver, its valuation was set at the figure of $[illegible], but that owing to the development of the Scott's Run field the road now has a value of approximately $[illegible].

The I. C. C. refused to authorize the **West Virginia Northern Ry. Co.,** owned by J. W. Mercer, to take over two small [illegible] from [illegible] owned by Weaver and [illegible] to the Eastern Mining & Power Co., on the ground that the West Virginia Northern's operation up to this time had not justified its existence as a railroad and because no public interest demanded the acquisition of the piece of track, less than [illegible] long, at a cost of $91,000 and the [illegible] a cost of $[illegible].

Association Activities

Northern West Virginia Coal Operators' Association

Representatives of the association held a conference with transportation officials of the Baltimore & Ohio late in October with a view to securing some relief from the situation, under which coal originating in northern West Virginia fields is debarred from Western shipments owing to embargoes. Operators called attention of the B. & O. officials to the fact that coal originating in Ohio was being permitted to go forward to the Lakes at a time when West Virginia coal was being debarred and it was inferred that the embargoes under such conditions were to be regarded only as discrimination. The railroad is said to have taken the position that more business can be handled from the Ohio mines than from West Virginia mines in a given length of time and therefore the shorter haul is to be preferred as a matter of dollars and cents, and officials of the railroad are said to have frankly stated that to representatives of the association.

Coming Meetings

The Illinois Mining Institute will hold its next meeting Dec. 1 and 2 at the Illinois Union Bldg., cor. Wright and John St., Champaign, Ill. Secretary, Martin Bolt, Springfield, Ill.

West Virginia Coal Mining Institute's annual meeting will be held Dec. 5 and 6, at Huntington, W. Va. Secretary, R. E. Sherwood, Kanawha Bank Bldg., Charleston, W. Va.

Coal Mining Institute of America will meet Dec. 13, 14 and 15 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., 911 Chamber of Commerce Bldg., Pittsburgh, Pa.

National Exposition of Power and Mechanical Engineering will be held at the Grand Central Palace, New York City, Dec. 7-13. Manager, Charles F. Roth, Grand Central Palace, New York City.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 22 NEW YORK, THURSDAY, NOVEMBER 23, 1922 Number 21

What of the Outlying Districts?

IT IS going to be difficult to explain to the average citizen why the operators of the old Central Competitive Field are so determined that the operators of the outlying districts shall not have a direct voice in making the next wage agreement for the country. The spectacle at Chicago last week of operators divided into a dozen "camps" but with practically all of the men representing the "four-state" region clinging together on the one issue of keeping others out of their councils raises all the questions to which Harry Taylor, of Kansas City, and C. H. Jenkins, of Fairmont, gave voice at the joint conference.

Why should producers of less than 50 per cent of the country's soft-coal tonnage set a scale which others with no voice in the setting must follow as best they can? Why is it not possible for a basic price on mine labor to be established for the whole country, with legitimate variations by districts—as the price of nails was once fixed? Why cannot a joint national wage board make adjustments of labor scales in districts hard pressed by non-union competition so that those districts can meet that competition on something like even ground? It might be arranged in some industries, why not in coal?

The average citizen hardly appreciates the strength or arrogance of the United Mine Workers of America. He hardly realizes how necessary it is for cohesion and unity of purpose among whatever operators are to deal with that union. He may not know, even after the exhibits of Cleveland in August and October, that it is always difficult to unite the operators even of a single section of the country on any program and that marshaling the operators of the whole United States to present a solid front seems impossible. He is too ignorant of the intricacies of coal diplomacy—spare the word!—to understand that the longer the operators' front, the greater the number of weak spots and therefore the easier it is for a powerful union to segregate the groups and pick off the softest of them when any emergency arises.

As for varying wages from a national basic rate, the experience of the past is sufficient indication of what would happen at every operators' effort to *reduce* a district level. The United Mine Workers of America would rather close up a union field than reduce its wage to compete with non-union territory. Its principal effort would be to unionize that competing open-shop territory—barring obstacles such as the injunctions granted by Judge McClintic against organizers in the southern West Virginia regions. And could any joint body of union miners and operators make district adjustments on a scientific basis? Wouldn't it invariably be merely a test of strength?

Even though some impossible proposals were made by the outlying districts at the Chicago conference, not all the seed planted there fell on barren soil. Proposals for the creation of closer community of interest among operators won attention. Suggestions for the establishment of various services of mutual value to operators throughout the land caused more than one delegate to say: "What that really means is: The National Coal Association ought to be stronger." And perhaps the National Coal Association is stronger in certain minds because of the thought which some of the Chicago discussion provoked. Perhaps an element or two of a better national consciousness in the industry was introduced.

The participants in the Chicago conference seem to have appraised aright the functions of the new coal commission in relation to their difficulties. That is to say they are not counting on that body to solve their mutual problems of a wage scale to replace the contract now in effect. The coal commission is the ear and voice of the public. It is not even indirectly charged with the problems facing the joint conferences of miners and operators.

The commission will, however, be much concerned over the failure or success of this joint conference in preventing a strike in 1923. The public is looking to the commission to tell it the facts about the situation. There is no more serious or important responsibility imposed on Mr. Hammond and his associates than this, particularly because it calls for the exercise of judgment, the picking of the wheat from the chaff, even before the commission will have had opportunity to familiarize itself with the huge task that confronts it.

Shall We Weep or Think?

IT IS seldom that so much plain talking, straight thinking and common sense about coal are found in one place as in an editorial article in the November *Survey Graphic*, entitled, "What Lies Before the New Federal Coal Commission." It is all the more surprising that such a broad statement, which, while directed at the commission as suggestions and advice, may be taken to heart by all interested and connected with the subject, should be found in this publication. Perhaps the answer is found in an editorial in another part of the same paper, where in respect to the coal commission and its work it is noted: "Or shall we too try to use our minds—the thinking part of our minds, not the weeping part, not the merely emotional parts, not the merely volitional parts? Shall we try to understand our way through this coal problem? It might be the beginning of the new age."

The *Survey* must be using the thinking part of its mind, not the weeping part. It is a good sign. It is good advice also that the *Survey* suggests to the commission—"devoting more effort to disclosing wastes than to running down profiteers, more thought to laying foundations for peace and a stable supply of coal than to finding who shot somebody in Mingo County."

We would like to emphasize by repetition two main thoughts conveyed in that article. They are that "the

Why Wonder?

JUDGMENTS are relative. They are based not on the facts themselves but rather on comparisons with the usual or with what in our lack of systematized and statistical knowledge we regard as usual. We cannot demand of anyone or any industry to be much better than the normal. We waste our time if we try for perfection in one place while in another grosser imperfections exist. Yet in many cases the self-appointed judge, the public, all unknowing, is not one whit better than the culprit that it judges.

The Fact Finding Coal Commission, representing in its august person the American public, will do well to keep in mind this important fact lest it condemn the coal industry for faults which the public both within and without industry has in common with it. In fact, unless the commission has a chart to guide it, it may go grievously astray by failing, as most of us do, to evaluate rightly just what is usual and what unusual. To this no reference is made to moral obliquity, for no industry is justified in breaking the law. Only such matters as overcapitalization, overmanning, irregularity in operation, inefficiency, waste and the frequency of accidents are referred to in these reflections.

It might be well to elaborate on the last and see if the hands of the public are so clean that they can rightly assail the coal industry. On the face of things the showing of the coal industry is bad. About 2,000 lives are lost per year in the coal mines of the United States. Everyone understands that some lives must be lost in industry and elsewhere, inevitably or as a result of carelessness, but why so many in coal mining?

The Committee on Public Accident Statistics of the National Safety Council, in a pamphlet entitled "The Trend of Public Accidents" declares that 76,000 lives were sacrificed by "accidents" in 1920. Would anyone imagine that it was anything like so many? Our idea of the usual, that usual on which all our judgments are unconsciously based, whether we know it or not, evidently is erroneous. It is necessary that we be given a yardstick as a basis for our calculations or we shall go grievously wrong.

Do we know, for instance, that the fatal accidents from falls throughout the continental United States were 12,557 in 1920 and that automobiles killed 11,067, each considerably over 30 per day? Do we know, for example, that 8,088 people died of burns and 7,769 from railroad accidents? To put it another way, almost as many people throughout the United States are daily killed by falls and automobiles as perished recently in the terrible explosion at Spangler.

To shift to another phase of the same subject, it is altogether likely that the commission will frame a more effectual indictment, based this time on a comparison and therefore more capable of sinking deeply into the public consciousness. If it does not it will be unlike every other body of inquirers that has canvassed the coal situation. It will compare the record of the mines of the United States with those of Great Britain and other European countries. The comparison, at first sight, is one calculated to make the coal industry squirm, for the European accident figures are much below our own. In 1920 the fatality rate in Great Britain was 0.88 per thousand employees and in the United States it was 2.98, or roughly three times as many.

The rate per million tons of output, it is true, told a different tale. It was 4.60 in Great Britain and only 3.51 here. But stress inevitably will be laid on the loss per thousand lives, forgetful that in America a larger percentage are exposed to hazards than in Great Britain and that the hazard of actual coal extraction is comparable to that which menaces trainmen in railroad work. It is the real hazard of the mine as is train service in railroading.

As, however, no reference to the tonnage per fatality or to the fatalities per million tons are likely to move the public and as the other consideration is a technicality too puzzling for the man who wants his thinking made easy, it would be well to refer again to "The Trend of Public Accidents" and learn from it that we "have in this country nearly 37,000 accidental deaths in excess of what we would have if the accident experience of England and Wales were to prevail here" and that "in proportion to population the United States reports nearly twice as many accidental deaths as England and Wales. The mortality from falls, transportation and vehicular accidents and burns is greatly in excess of that prevailing in the older country. The railroad accident death rate of the United States is more than four times that of England and Wales! Automobile accidents in the United States show more than twice the death rate in England and Wales! Four times the number of fatal street-car accidents and injuries!"

Clearly then, it is only the British, or rather the European, and not the American public who can criticise our mine death rate, for it is merely a reflection of our general attitude toward safety.

When the Fact Finding Commission makes its report and points out how much greater is the death rate in mining in the United States than in Europe we hope that it will add with all due emphasis that all fatality rates in industry and public life have a similar trend, that intoxication of action or some other characteristic makes the American venturesome beyond most others of his kind and exposes him to sudden death. Why wonder that what is found true in all other walks of life is true also in mining?

Wire Rope Is Tough, but Faulty Installation and Careless Operation Quickly Destroy It*

By J. F. Howe†
Worcester, Mass.

Reverse Bending and Overlaying of Laps Are Costly—Frequent Inspection of Rollers Profitable—Relation of Drum to Rope Diameter —Where Wear Is Severe Large Wires May Be Used Exteriorly

ALMOST every coal mine is using haulage systems of one sort or another. Where the grades are light and electrical power is available, wire rope is not employed. When the grades are steeper, however, rope haulage is found to be more economical than electric traction. Two general systems are employed: (1) Endless and (2) tail-rope haulage.

The endless-haulage system consists of a rope with the ends spliced together and actuated by wrapping it several times around a pair of drums driven by either steam or electricity.

The tail-rope haulage system consists of two separate ropes, one a head rope attached to the load to be pulled and the other the tail rope which is attached to the rear end of the load. This latter rope is used to pull the empties back into the mine.

In the endless-rope system, grips are employed to attach the mine cars to the rope in groups of one, two or three cars, several such groups being thus attached. As fast as the coal cars are emptied they are connected to the return side of the system by grips and are hauled into the mine by the same rope that pulled them out. One or two men at the mine entrance with a similar number of men in the mine attach and detach the cars. Endless ropes up to about three miles long and ranging in size from ¾ in. to 1¼ in. in diameter are frequently found. The rope construction usually employed in sizes from ¾ in. to 1⅛ in. inclusive is known as "haulage rope" and consists of six strands each of seven wires wound around a hemp core.

The grade of rope used depends largely on the friction, or wear, to which it is exposed. Crucible, extra-strong crucible and plow steels are ordinarily used.

For sizes as large as 1¼ in. the construction is frequently modified from the 6x7 to what is known as 6x19 Seale Patent, this depending on the size of the drums and the bending to which the rope is subjected.

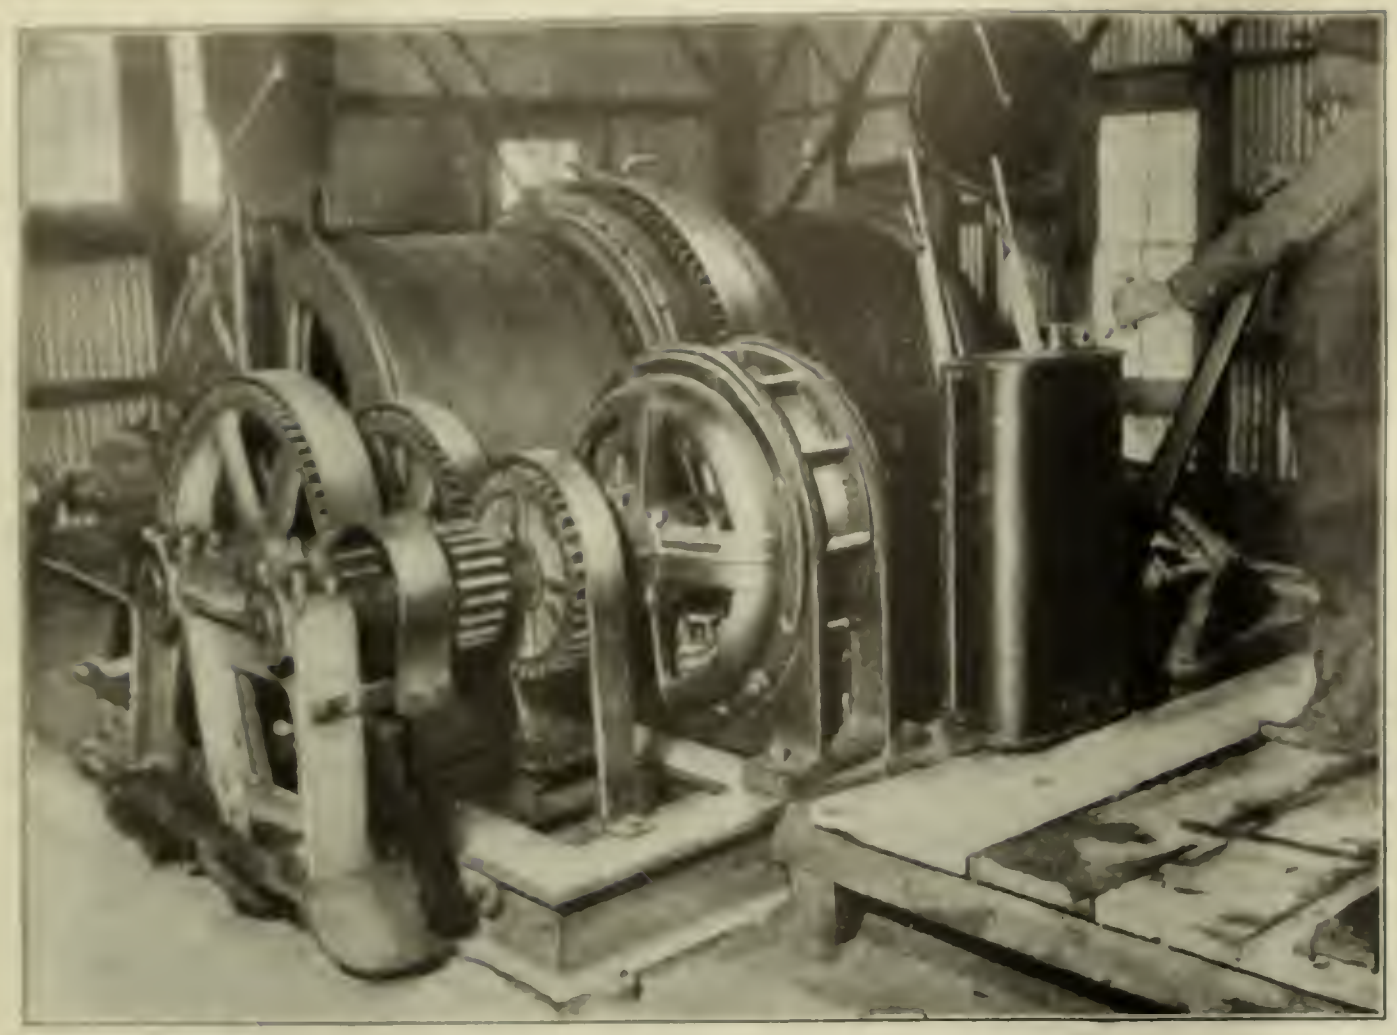
For the driving mechanism the best practice is to thread the rope around the two drums in an elliptical path. This prevents any reverse bending of the rope, which is a bad feature and which should be avoided wherever possible. At some places where the design was originally not sufficiently liberal to prevent slipping, the rope is threaded from drum to drum in the form of a figure eight, but this way of obtaining a large contact of rope with the drum and greater frictional stress is destructive and shortens the life of the rope. It is not to be recommended. Each groove of one of the two drums should have a slip ring so that the tension may be equalized and the accumulation of strain on the ropes while passing around the drums may be prevented.

On endless-rope systems the customary practice is to use regular lay rope, because this is more readily spliced in a satisfactory manner and can be operated with less trouble for that reason.

Drums for endless-rope systems will give good results if proportioned to the diameters in Table I.

TABLE I—RELATION OF DRUM TO ROPE DIAMETER, ENDLESS ROPE HAULAGE

Rope Diameter, Inches	Drum Diameter — 6x7 Rope	Drum Diameter — 6x19 Seale Patent	Drum Diameter — 8x19
¾	54	48	42
⅞	54 to 90	48 to 72	42 to 60
1	60 to 84	60	48 to 66
1 ⅛	72 to 84	66 to 84	54
1 ¼	84 to 96	72 to 96	60 to 78
1 ⅜	96	84 to 108	72 to 90
1 ½	108	96	84



The figures in Table I represent practice in successful systems and coincide with theoretical values for low bending stresses. A suitable number of wraps of rope around the drums is necessary in order to produce sufficient friction to drive the rope. If the diameter of the drum is reduced, then it becomes necessary to use more turns to obtain the tractive effect or to increase the tension on the rope by adding to the counterweight. This method of increasing the tractive effect is not advisable if it increases the load so that the safety factor is reduced below what should be considered safe practice—i.e., 6 or 7. It will be found that the splices hold much better if the tension is not too severe.

In the tail-rope system two drums are employed, one for the head rope and the other for the tail rope. In general, the head rope is the larger of the two, for it has to pull the loads up out of the mine and the tail rope has only to let the empty cars down the same grade.

In a few cases where the grades are reversed the tail rope is made as large as or larger than the head rope. In the tail-rope system, particularly when the distance to be traversed is long, the rope frequently has to be

*First instalment of an article from a paper entitled "A Discussion of Wire Rope as Applied to Mining ..." read at the autumn meeting of the Rocky Mountain ... Association, Glenwood Springs, Col.

†American Steel & Wire Co.

Grooved Drums Save Rope

In the illustration the unoccupied grooves show on the left-hand drum. Where the angle of approach is not greater than 1½ deg., the rope winds into the groove practically without friction except for the slight wear on the sides of the channel and this is always far less damaging than the abrasion of a rope winding against the rough surface of the rope of the preceding turn, as it always does when the drum is flat. The grooves maintain a clearance between turns of at least ¼ in.

wound from four to ten layers deep on itself. The drums should be as large in diameter and as wide as possible to reduce this overlaying of the rope on itself, for when it occurs the effect on the rope is quite destructive. It is of great importance, also, to see that every layer of the rope winds smoothly and evenly on the drum, for if it starts to wind unevenly, the wear on the rope is increased materially and the rope may be injured at some one point as the result of its becoming wedged between the layers on the drum. It is therefore necessary in the installation of a new rope on such a system to see that from the outset it winds smoothly and evenly on the drum. If this is done the rope usually will follow its original winding and give no further trouble. If it does not, however, the life of the rope will be materially reduced because wear will set in at some one spot.

In using a tail-rope system the proper arrangement of supporting sheaves, turn sheaves, rollers and idlers is quite important. The upkeep of these will in a large measure determine the life of a rope. Wherever crossovers exist, for instance, suitable means should be taken to prevent the rope from coming in contact with the steel rail, because the rope, though hard compared to the face of the rail, contains a much smaller metallic section and consequently a slight wear of the rope from such friction involves the user in an appreciable loss.

In mail mines particularly lumps frequently drop off the cars onto the track and clog the rollers or at least prevent them from turning freely. Whenever a roller ceases to rotate it is rapidly worn by the rope and in turn will wear the rope. I know it is a difficult matter to keep every roller on a system of any considerable length always in condition so that it will turn when the rope comes in contact with it, but suitable supervision and regular inspection will eliminate the chronic cases which would otherwise produce bad results and excessive rope wear.

A few words with regard to rollers may not be out of place at this time. They should be light enough that they will start turning when the rope comes in contact with them. Some prefer chilled cast-iron, but others use wood. When the bearings of a roller get out of line due to wear or improper support it tends to bind and refuse to turn with the rope. A suitable frame with bearings rigidly attached and accessible for oiling, repair or renewal is a fundamental requirement. As far as possible, it should be designed so that dirt or material that may fall from mine cars will not cause it to clog.

Rollers should be wide enough so that the rope will stay on them. Where they are too narrow the rope jumps off them and rubs over the sides of the rollers or their bearings and suffers wear accordingly.

One type of roller for which special merit is claimed consists of two portions which taper toward the center. They are, of course, mounted on a spindle. The rope with such a roller always tends to travel toward the center, and here is placed a hardened steel sheave which will start up instantly when a moving rope comes in contact with it. A liberal bearing on the spindle reduces the wear to a minimum. Such a roller must be carefully lined if the best results are to be attained, but nevertheless this roller has its advantages, for its central sheave, being light, prevents wear of both rope and roller. It has been tried out in the South African mining fields and has been regarded with much favor. Operating tests of it are being made in this country.

Judging by the general experience of rope manufacturers and mining engineers, a more intensive study of the design of mine rollers would produce results of value to both. The bearings on rollers as a rule are not designed for the speed at which they will be run.

All that has been said about the rollers with the tail-rope system applies with equal force to those used with an endless rope, but with the latter the action and wear of the grip should be considered. It is important also that the grips be bell-mouthed on both ends so that there will be no sharp corners where they come in contact with the rope. Grips also should be smoothed out so that there will be no rough spots when a new grip is

put on. Such rough surfaces cause rapid wear on a rope, which does not stop until the grip has been worn smooth. The rope will always slip a little when the grip is applied or released. Summing up, the main need is to reduce the friction on the rope as far as possible, because friction means wear, and wear means shortened life.

In the tail-rope system the wear on the rope always is greatest on the end that is attached to the cars, for it is that end which travels the greatest distance and comes in contact with the largest number of rollers. It is the usual practice at mines employing the tail-rope system to cut off at regular intervals between 1,000 and 2,000 ft. of the end attached to the cars and to splice a new piece of equal length in at the drum end. This keeps the tail line in good condition. Another method is to use a head line for a certain period, then switch it over and splice it into the tail line, putting a new rope on the head line.

It is an open question which is the better of the two systems of haulage, endless or tail-rope haulage. The tail rope is of course intermittent in operation, and the number of cars in each trip will run from forty to sixty.

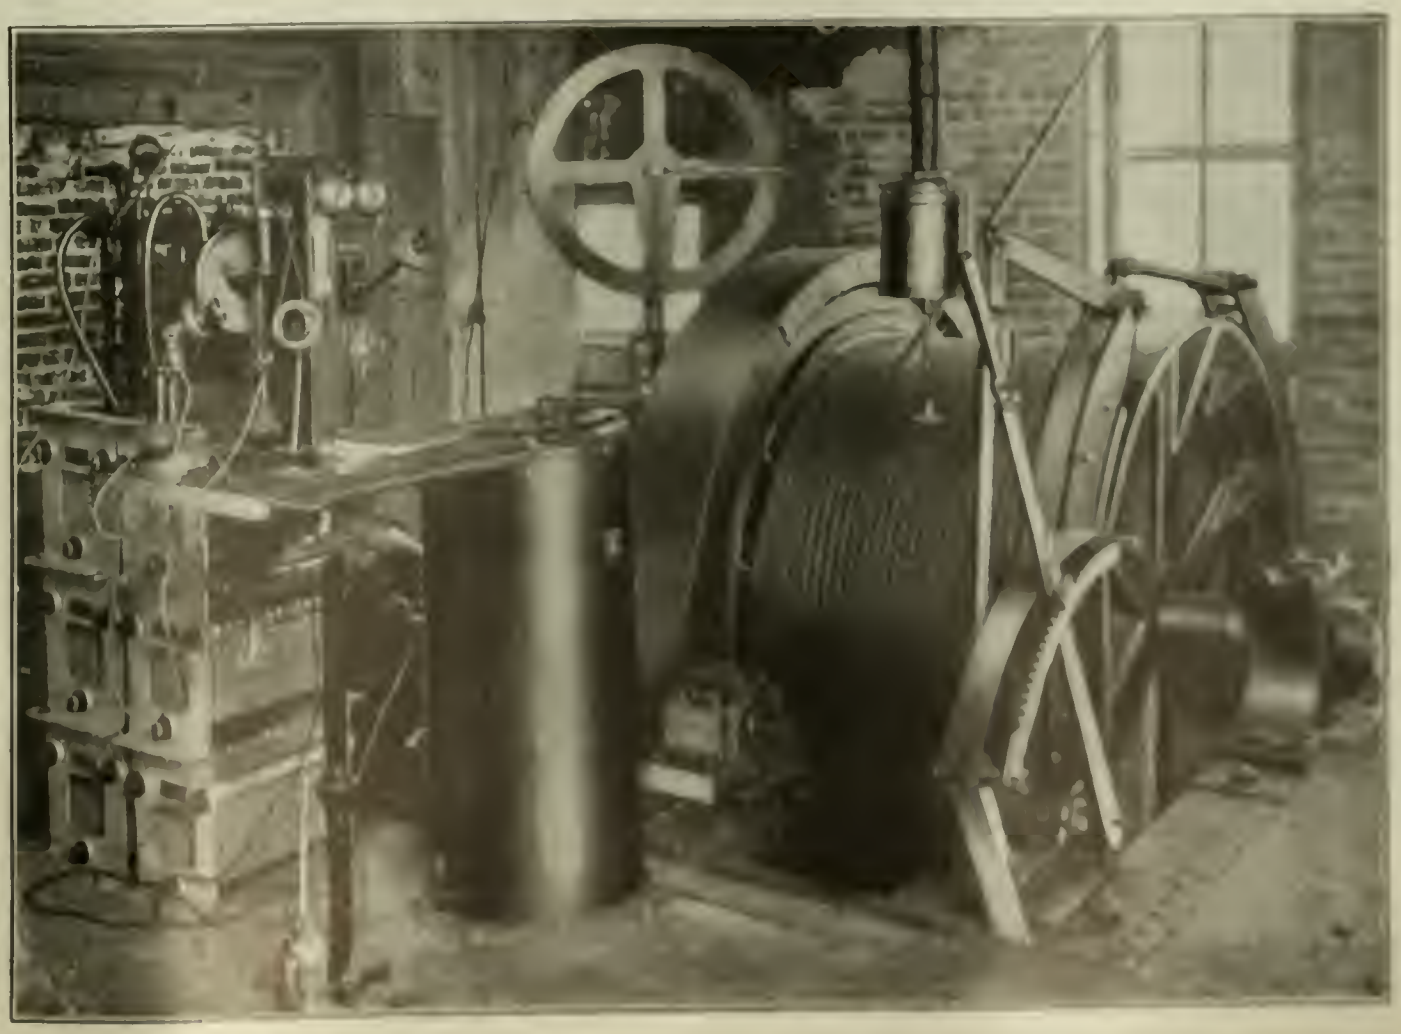
The ropes employed for head lines usually are ⅞ in., ⅞ in. or 1 in., and for tail lines, ½ in., ⅝ in., ¾ in. or ⅞ in. Head lines may run up to 10,000 or 12,000 ft.; the tail lines from 20,000 to 24,000 ft. Branch tail lines are used in entries further to enlarge the sphere of operation of this system.

On outside inclines, the pitch of which usually is fairly steep, ropes are employed ranging from 1 in. to 1¼ in. in diameter. In this case it is frequently found that a rope of a special construction will give better results than the ordinary 6x19 hoisting rope, for in this instance the important condition to be met is the wear on the rollers and not, as with a rope hanging in a vertical shaft, only the stresses due to the bending and the frictional wear at the drum and head sheave. Consequently, on an incline a rope should be made with wires of somewhat larger cross-section than are used in a rope for a vertical shaft. As such ropes are special, the mine that uses them must always carry a spare rope on hand ready for installation, for manufacturers are not likely to carry such ropes in stock.

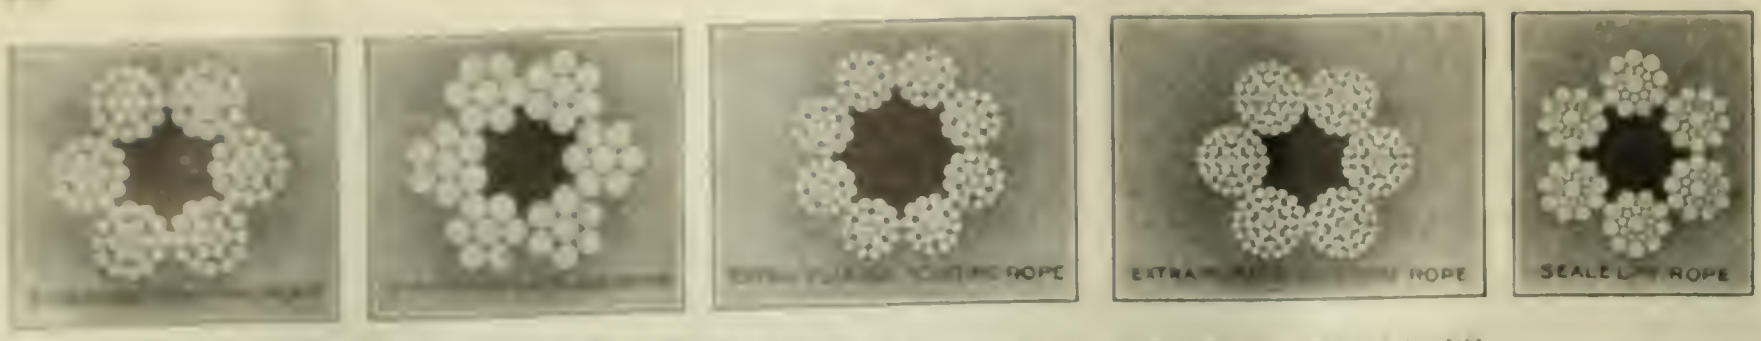
There are, doubtless, many inclines where an improvement in rope service could be obtained by a close study of the conditions of operation. Certain points with regard to wear on ropes always should be borne in mind. The softest material used in rope manufacture (excluding iron, which is not now used in the construction of ropes for mines) is crucible steel. If we grade rope materials in accordance with hardness or wearing qualities, they are as follows:

(1) Crucible steel
(2) Extra-strong crucible steel
(3) Plow steel
(4) Monitor or improved plow steel

Plow steel and monitor grades are coming into use more and more for inclines and haulages, because these ropes have maximum wearing qualities.



In foreign practice it is customary, after deciding on the size of rope, to calculate the construction which will give the best service in this diameter, and then proportion sheaves and drums to fit the size and character of rope. American practice, however, differs from this, as it proportions the sheaves and drums solely to the diameter of the rope. On haulages the drums as a rule should be designed for ropes of six strands of seven wires; on inclines and shafts, for ropes of six strands of nineteen wires, or some modification of nineteen wires such as in the Seale patent rope.



In considering ropes for shaft use, the term "shaft operation" will mean the raising of mine material to the surface either vertically or on what might be termed a steep incline. If the incline is less than 45 deg. it probably would be termed a slope; if more than 45, it would be termed a shaft.

The condition on a slope is identical to that on a gravity incline except that the load has to be pulled up in-

Overlaying Shortens Rope Life

By winding one layer over another a small hoist drum can be used, but the movement of one piece of rope on another will cause unnecessary wear and even injury to both. In a case of the kind illustrated here the only factor to justify so much rope on the drum is that the cost of a drum of proper size might overbalance the saving made in prolonging the rope's life by proper winding.

CROSS SECTIONS OF FIVE DIFFERENT MAKES OF HAULAGE AND HOISTING ROPE

...wires will not break too readily they ... of small diameter. The rope on the right ... are made of larger diameter than with hoist- ... has the wearing qualities of the haulage ... ing rope. This increases flexibility and ... rope and some of the pliability of the hoisting ... injures them when they are passed around ... rope. It wears down more than the other ... drums or sheaves, especially when these are ... rope without indicating it by broken wires.

...sired of being lowered. As on a gravity incline so also on a slope, a rope of special construction that will afford maximum wear frequently is needed. Even more careful attention should be given to the rollers on a slope or gravity incline than is necessary on a haulage system, for the speed usually is greater, and a roller either worn or refusing to turn would soon wear the rope out.

In a shaft operation the conditions which govern the life of a rope are the size and location of the sheaves and drums, the load hoisted, the speed of the hoist, its acceleration and such local conditions as corrosion by mine water.

As a rule the drums employed for shaft hoists are much larger than for any other type of operation. There are several reasons for this: In the first place, it is desirable to have the rope wind on the drum in one layer, because when so wound it is not subjected to the wear and crushing which is inevitable where overlaying is permitted. Where the shaft is deep, this, of course, requires a drum of large diameter as well as considerable width. It also is desirable that the drums be grooved to fit the diameter rope to be used, the grooved drum giving a support to the rope which a flat drum does not.

Furthermore, the grooved drum assists in the winding of the rope evenly across the entire width. If conditions are such that a rope must wind on a hoisting drum in more than one layer, it should be borne in mind that the service obtained can never be as good as if the overlaying could be eliminated. Extra wear usually comes where the rope starts to make the overlay, due to the slap as the direction of wind is reversed.

A TWO-THOUSAND-FOOT HAULAGE PLANT

Drum or sheaves to be used in shaft mining should be of at least twice the diameter designated in the trade catalogs, for such literature must cover a wide range of uses, and although the sizes recommended are larger than are used in some places, they are smaller than those usually obtaining at mining operations. A rule that is used abroad to a large extent is to base the diameter of the drum or sheave upon the diameter of the wire in the individual rope, the practice being for rope of 1¼ in. diameter and 6x19 stranding to use a sheave or drum not less than 7 ft. in diameter, that size corresponding to about 800 times the diameter of the wire. This minimum, however, is not considered good practice. The value of 1,000 times the diameter of the wire corresponding to a sheave or drum diameter of 8½ ft. is considered desirable and an even larger one corresponding to 1,200 times the diameter of the wire would be preferable if it could be arranged. This would mean a sheave or drum 10 ft. in diameter. I think the practice in the United States frequently is to use larger than this, drums and sheaves up to 12 ft. in diameter being used for 1½ in. 6x19 rope.

TABLE II—PROPER DRUM DIAMETER FOR 6x19 ROPE

Rope Diameter, Inches	Drum Diameter, Feet	Rope Diameter, Inches	Drum Diameter, Feet
1	8	1⅝	13
1¼	9	1¾	14
1⅜	10	1⅞	15
1½	11	2	16
1⅝	12		

Sheaves or drums of large diameter will lengthen the life of rope by decreasing the bending stresses to which it is subjected. Where the drum or sheave is too small, wires begin to break and when a certain number have broken it is necessary to remove the rope. With a large drum or sheave the rope wears out slowly and has a far longer life.

Did Not Have Bureau of Mines Approval

H. FOSTER BAIN, director of the U. S. Bureau of Mines, corrects the statement taken from the report of the official investigator of the explosion at No. 4 Mine of the Canadian Collieries, Ltd., and quoted on page 669 of the Oct. 26 issue of *Coal Age*, to the effect that the coal-cutting machine in the workings where the explosion took place was of a type approved by the U. S. Bureau of Mines.

He states that "the Sullivan Machinery Co. advise that this was a totally enclosed machine of a type especially built for use in foreign countries and in Canada, and differing in design from the Sullivan machines approved by the Bureau of Mines. The company further advises that this equipment did not bear the Bureau of Mines approval plate, which indentifies all permissible equipment approved by the Bureau."

How to Make Babbitted Bearings That Will Last Long And Run Cool and Smoothly

Dried Clay Solution on Mandrel—Ladle with Round Spout Preferable —Avoid All Dampness—How to Gage Correct Temperature—Casting Base and Cap in One Operation—Providing Oil Holes and Grooves

By Gustav H. Radebaugh*
Urbana, Ill.

BABBITT metals are divided into three classes: (1) Alloys of tin, antimony and copper; (2) alloys of tin, antimony, coppper and lead, and (3) alloys of tin, copper and zinc. The name "babbitt" is derived from that of the man who invented the lining of bearings with soft metal, Isaac Babbitt. The term "babbitting" has been applied to the process of applying soft anti-friction metals inside a hardened shell for the purpose of producing a smooth and cool-running bearing.

Babbitt metal is extensively used. It can be purchased from most dealers in machinery and from repair or jobbing shops. It is marketed in the form of small blocks or pigs. One of the difficulties in the use of this metal is the formation of blowholes if the bearing is not properly cast. It has been found that these can be avoided if the mandrel, or shaft, while heated is lightly covered with a solution composed of one or two pounds of Jersey red clay to three gallons of water.

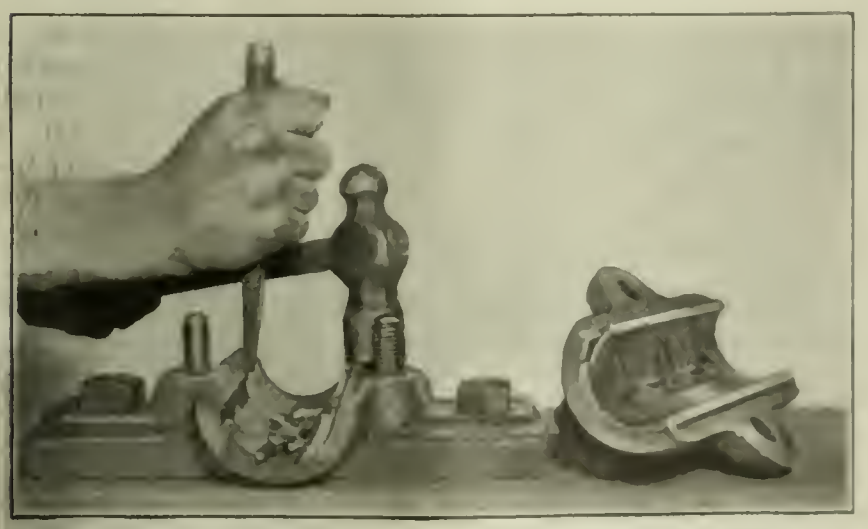


FIG. 1—REMOVING OLD LINING FROM BEARING
A flat cold chisel is driven into each side of the box between the babbitt lining and the cast-iron shell, thus causing the former to break loose. Oftentimes it will be removed in a single piece.

This will prevent the formation of bubbles and the lining, in consequence, will have a smooth surface. Oil causes the babbitt to blister.

It is important that the metal always be poured from a ladle that has a rounded spout rather than one that is flat and sharp, for the latter tends to produce a porous area or blowholes in the solidified metal. Putty is preferable to clay for luting or sealing the ends and sides of the bearings, as the moisture in the clay tends to cause sputtering. Exercise caution when pouring babbitt into a box; be absolutely certain that the inside of the box is dry. If damp it causes the heated metal to sputter and sometimes it explodes with force enough to scatter molten masses and particles over a wide range.

*University of Illinois.

Prior to pouring the babbitt the bearing should be heated to prevent the molten metal from becoming chilled and sluggish. The common method of determining the pouring temperature of babbitt metal is by

FIG. 2—ANCHOR HOLES KEEP BABBITT IN PLACE
If no anchor holes have been provided they should be drilled and if the babbitt has not come out of them when the lining is removed care should be taken to see that they are clean so that the new lining will not slip.

testing it with a dry pine stick. If it chars the wood, the metal is at the correct temperature for pouring. Never heat the babbitt to red heat. This will destroy its usefulness. When heating the babbitt in a forge fire be careful that none of the metal is scattered in the fire, for it will find its way to the tuyere iron and close up the blast openings.

The old babbitt is removed from bearings by taking a flat cold chisel and driving it into each side of the box between the babbitt lining and the cast-iron shell. The old babbitt will break off in the manner shown in Fig. 1. This is not a difficult operation, as in many cases

FIG. 3—LINING AND LEVELING MANDREL OR SHAFT
Round wedge blocks bring the mandrel up to position. When these is done the blocks are poured solid with babbitt and paper shims are used to give the final adjustment. Before this is done the center line of the shaft will be set to correspond with that of the box.

FIG. 6—CUTTING GROOVES TO SEPARATE BASE AND CAP
Adjacent arc shown at right that will in time cut both. Small cutting are run along the inside edges of the liners so that the babbitt poured into the cap will run down and fill the holes with-out. Reinforced backing shows a solid retaining lining as will make

the entire piece of babbitt is removed intact. The old metal can be remelted and used again. If the box is covered with oil and muck, place the base and cap in the forge fire and heat it until the oil burns off.

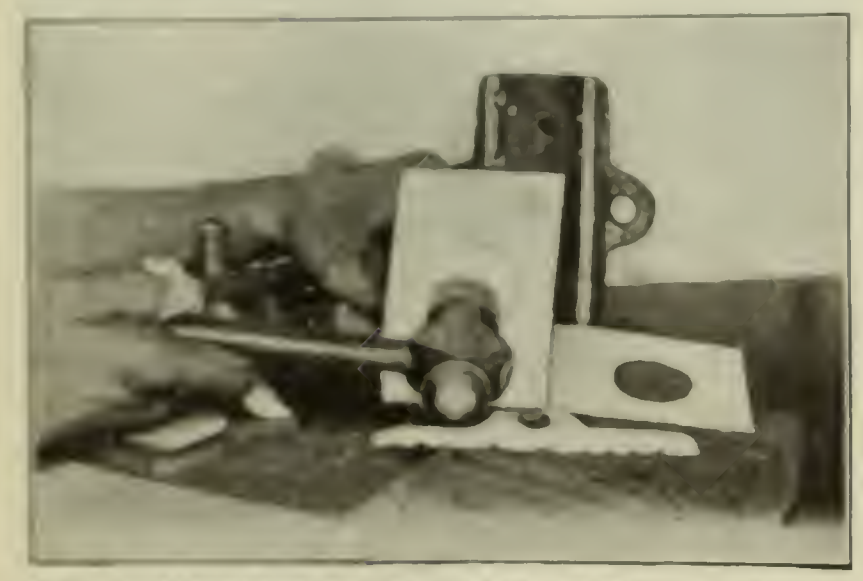

FIG. 5—PAPER STRIP KEEPS BABBITT FROM CLAY DAM
Babbitt metal if coming in contact with moisture creates steam an explosive gas of intense heat is instantaneous in an explosion. After joints have been ladled to know out water and to dry the bear-ing thoroughly it should be thoroughly dried out the babbitt runs. In ordinary work clay or putty, as an exception, or at least blowholes, would result. The paper strip serves as a protection.

The anchor holes in the base and cap of the box are shown in Fig. 2. These anchor holes are used to hold the babbitt lining in place. Cast-iron shells are rarely ever lined, though this is a common practice where the

FIG. 3—PLACING THE PAPER LINERS IN POSITION
Before these liners are placed the cardboard box is heated on an oil stove or over some other heating device to remove the moisture and dry it out. A gas heating stove is made a good thing and a gas or alcohol torch can be used to

shells are of bronze, like those used for automobile engines. If these anchor holes are not in the box and no other method is provided they should be drilled, as it is important that the babbitt lining be held in place by some such means. When removing the babbitt the anchor holes sometimes remain filled. They must be clean before the shell is reabbitted. One of the best ways to remove the metal left in the holes is by heating the box in the forge fire.

After the box has been thoroughly cleaned from all

FIG. 7—CLAMP CAP WITH BOLTS; SEAL WITH PUTTY
The bearing is now ready for pouring; liners, clamps, paper ends and clay or putty being all in place and the mandrel properly lined.

loose babbitt, metal and oil, the shaft, or mandrel, is then located and properly lined and levelled. A useful way of blocking it into place is by the use of the small wedge blocks shown in Fig. 3. After the shaft is brought to the proper position by adjusting the wedge blocks, it must be more securely held by placing flat blocks under each end. It may be necessary to use paper shims in this blocking operation.

Liners are constructed to separate the base from the

FIG. 8—TESTING HEAT OF METAL WITH PINE STICK
The babbitt should be slowly heated and to the precise tempera-ture at which the metal will char a pine stick, without actually burning it. Be sure you have enough metal to complete the job. The cast should, of course, be continuous.

cap of the box. By cutting the small notches along the inside edge of the cardboard liners both the top and the bottom of the lining can be poured at the same time. These notches are cut in the manner shown in Fig. 4. They are large enough to permit the molten babbitt to reach the base but small enough that the cap can be readily pried free after the babbitt has been poured and has become cooled.

Paper ends or washers, as shown in Fig. 5, are used to keep the hot babbitt from coming in contact with the damp clay or putty which is used for sealing the ends and sides. These dams are used to prevent the hot metal from escaping. If the hot babbitt comes in contact with moisture it tends to sputter. Before placing the liners, therefore, as shown in the next operation, the cast-iron box should be heated. This will insure a more even flow of the metal.

After the liners have been put in place and the shaft

FIG. 9—SKIMMING SLAG OFF SURFACE OF METAL

Babbitt metal tends to break up into its metallic constituents, therefore to keep the mixture up to standard throughout it should be stirred and the refuse that rises to the top should be carefully skimmed off, taking care, however, that this metallic scum does not get into the bed of the forge, for it will block the tuyere iron and close the blast openings.

properly lined up, the cap is ready to be placed on the base. It is good practice to clamp the cap in position with two bolts, as it insures its remaining in proper location. All the open edges are sealed with putty or clay as shown in Fig. 7. Good luting materials are putty, fireclay or ordinary clay. The bearing cap should be provided with a hole for pouring the metal through and one or two holes to permit the escape of gases. These holes on a bearing such as is shown should be $\frac{3}{8}$ in. in diameter.

The babbitt scrap that has been removed from the box with the necessary quantity of new metal is placed in a ladle and slowly heated until a dry pine stick will char when placed in the molten metal as shown in Fig. 8.

Do not heat the metal to a high temperature. If the metal is too hot the pine stick will fire. It is not good

FIG. 10—POURING THE BABBITT METAL INTO BOXING

The bearing cap should have a hole for the pouring of the metal and one or two holes about $\frac{3}{8}$ in. in diameter for allowing the escape of gases. The ladle should have a wide and rounded spout, as shown, if the metal is to be poured satisfactorily

FIG. 11—BREAKING BOND BETWEEN BASE AND CAP

After the metal has solidified, the clamp bolts are removed and with a chisel the base and cap linings are broken loose from each other. This should be done first on one side and then on the other so that there will be no tendency to loosen the weld of the lining on the cast-iron shell.

practice to leave babbitt on the fire longer than necessary. It should be poured as quickly as it comes to the proper heat. To obtain a serviceable bearing these principles must be closely observed.

Before pouring, the babbitt should be stirred thoroughly to insure a lining of uniform composition. The metals in the alloy have a tendency to separate and seek different levels in the ladle, but the stirring overcomes that tendency. Previous to pouring, the top of the molten babbitt should be cleaned off as illustrated in Fig. 9, taking care that the refuse is not permitted to fall into the forge fire.

The babbitt must be poured quickly. One of the secrets of good bearings is the manner in which the metal is poured into the box. Failures are caused by having the box damp instead of warm, as suggested, by using a ladle with a sharp or flat pouring spout instead of a round spout, by not having the box ends and sides

FIG. 12—BEARING SHOULD BE INSPECTED

The cap and mandrel should be removed and the bearing inspected to see if a smooth job has been performed. If not it will be necessary to start all over again, as [illegible] adding metal after the pour has been completed

properly sealed and by not having enough material in the ladle to fill the bearing.

After the metal has been poured it should be permitted to cool and the cap should not be separated from the base till the metal has hardened. This operation is performed in the manner shown in Fig. 11. The clamp bolts are removed, and a flat cold chisel is driven between the bearing cap and the base. This causes the metal to separate at the points adjacent to the small notches in the liners, where the metal ran down into the

FIG. 13—SMOOTHING BEARING WITH COARSE FILE

All the fins and sharp edges must be removed and the edges rounded off to a fine radius. The bearing surface of the babbitt lining is next smoothed to a smooth, even finish. New liners are cut and so fitted that they will lie snugly against the shaft for without shimming it

base of the bearing. This operation should be performed on each side of the box so that there will be no tendency to loosen the hold of the bearing metal on the cast-iron shell.

In Fig. 12 the bearing cap has been removed, permitting the removal of the shaft, or mandrel. A close inspection can be made of the babbitt lining to determine if it will make a good bearing. It should be smooth and free from cold shorts. If defective, the babbitt lining is removed and the pouring operation is repeated.

When pouring a bearing the hot metal runs into the small crevice between the cap and base. This causes the babbitt lining to have fine and uneven edges. These should be removed by using the bastard, or coarse, file shown in Fig. 13. The edges of the babbitt lining should be filed to about a ¼-in. radius. The bearing surface of the babbitt lining should be filed and scraped to a smooth, even finish. The cap and base are fitted together, testing the fit of the bearing on a mandrel, or shaft. New liners are cut and fitted. They should be as thick as will permit the cap and the base to be bolted together with the clamp bolts without binding the shaft. In the cap of the box, oil holes should be provided. Holes used for gas escape are filled with babbitt during the pouring operation and it becomes necessary to remove this metal. One method is drilling with the breast drill as indicated in Fig. 14. Another effective method is to ream out these holes with wooden plugs, care being exercised that a free passage for air exists between the plug and the sides of the hole. After the metal cools these plugs are driven out and a clean hole is obtained, thus eliminating the use of the drill.

FIG. 14—DRILLING OUT OIL HOLES

Without oil holes many bearings would run hot. Holes are drilled in the babbitt lining with a breast drill. Care should be taken to keep the drill perpendicular to the surface of the bearing. Otherwise the oil hole will not be in the proper position for the passage of the oil to the shaft.

FIG. 15—CHISELLING OUT OIL GROOVES IN BEARING

These grooves are cut with a round-nosed goose-neck chisel and after they are made the bearing is smoothed with a half-round mill file and by scraping. They should be about ¼ in. deep.

The oil grooves are cut by using a round-nose goose-neck chisel as shown in Fig. 15. After the grooves have been cut, smooth the bearing down with a half-round mill file and by scraping. Grooves are cut in the surface of the bearing so as to distribute the lubricant evenly over the entire length of the journal. They are also cut so that they will collect the oil (which would otherwise run out at the ends of the bearings) and will return it to some point where it may be used again. The usual dimension of oil grooves is $\frac{3}{32}$ in. to ¼ in. in width and $\frac{1}{16}$ in. to ¼ in. in depth.

Using Rusted Sheet Iron as Side Plates for Chutes in Heavily Pitching Rooms

IN A certain anthracite colliery most of the mining is on the pitch and the grade is such that the car cannot follow the miner as the face advances, but must remain on the gangway. The pitches vary from 12 to 17 deg., so that the coal will not run without the introduction of chutes. These have a sheet-iron bottom and plank usually 2 in. thick on the sides. Thus the coal is carried from the face onto a platform or into the car.

The chutes that were left in the place when operations ceased on March 31 of this year were attacked by the acid water of the mine, with the result that when operations began again on Sept. 11 many of these chutes were no longer in fit condition to convey coal from the mine's face to the car.

Many chutes had been so badly attacked by the mine water that holes had been eaten through them. Some of the chambers are 250 to 300 ft. long and as each iron sheet is 8 ft. long the company had thirty or forty unserviceable iron sheets in each chamber. Just at this time much trouble was experienced in getting the necessary plank to complete the building of the chutes. So the problem was solved by the use of a sheet-iron cutter similar to that used in the breaker. This was brought into the mines and the sheet iron was cut lengthwise and used on the sides in place of plank.

Thus one unserviceable iron sheet 8 ft. long could be cut in two and made to take the place of a 16-ft. length of 2-in. plank. This was a big saving to the company, the only cost being that of buying the sheet-iron shears. Where there were any holes in the sheet iron the plates could be used with the damaged side down.

A Few Suggestions to Those Who Repair Mine Motors

Beware of Incorrect Connections Between Coils and Commutator —Be Sure That Both Bands and Coils Are Snug—Guard Against Bends, Twists and Blows That May Nick or Weaken Wire

By John S. Dean*
East Pittsburgh, Pa.

When the armature of a mine motor is damaged and has to be rewound, it is important that the connections between the windings and the commutator be made correctly. If the windings are not too badly damaged, the winder usually notes the throw of the leads from the coil to the commutator bar when he is stripping the windings, and in this way he gets the desired information.

Entire reliance cannot be placed on this method, as there is a possible chance that the winding may have been connected wrong when it was originally wound, either in the repair shop or in the factory. The only safe way is to get from the manufacturer of the motor this winding information, with a complete diagram of connections such as are shown in Figs. 2 and 3.

To be sure of getting the full life from an armature, extreme care should be taken to see that failure, from whatever cause, is guarded against in a satisfactory manner while the armature is being rewound. First of all, any sharp corners and any roughness in the slots that might damage the coils should be filed down and all chips and filings removed before the insulating material is applied to the core. In applying the insulating material on the coil supports it should be evenly placed and no thin spots allowed.

The coils should fit tightly in the slot and so that the tops of the coils are approximately $\frac{1}{32}$ in. above the outer edges of the grooves. If necessary, fillers should be used between the coils to meet these conditions. With the projection recommended there will be nothing to prevent the bands from being able to press the coils down tightly into place so that the former will rest finally on the iron core of the armature. Thus arranged the movement of the coils in the slots will be reduced to a minimum. If the coils are wound so that they come so high that the bands cannot be tightened enough to bring the coils flush with the iron core the bands will rest on the coils and not on the iron, and when the insulation dries out in service the bands will become loose.

The coils should not be twisted, bent or abused any more than is absolutely necessary to get them into place. Care should be taken not to get the wires or leads crossed in such a manner that when pressure is applied in banding, short-circuits will occur. The coils on the end windings should be down, so as to make a solid foundation for the bands, but care should be taken not to pound them to such an extent that the coils or leads are damaged.

Insulating protecting pieces should be placed at all points where the coils cross and where there is danger of short-circuiting. It is good practice to reinforce the insulation directly back of the commutator. This can be done by weaving braid between the leads or by taping the individual leads at this point.

The leads should be tinned back so far that there is no untinned copper in the commutator neck. The cotton sleeving on the lead should not be allowed to get into the commutator slot, as it may hinder soldering to such an extent that a poor connection will be made. The tool used in driving the leads into place should be free from sharp corners that might nick the leads, for a nicked wire is likely to break.

Mining motors usually are laid out for a wave or two-circuit type of winding. They may be wound with either a right- or left-hand coil. A right-hand coil is one where the leads come out on the right when the coil is held so that the portion to be placed in the bottom of the slot is toward you and the air-gap side of the coil is uppermost. A left-hand coil is one where the leads come out on the left when the coil is held so that the

*Motor engineer, Westinghouse Electric & Manufacturing Co.

FIG. 1

Armature Under Repair

The coils, properly insulated by their tape windings and by paper strips, are embedded in the core slots to such a point that when the completed job is bound with high-resistance wire the coils will come just flush with the slot opening.

FIG. 2—DIAGRAM AND DATA FOR ARMATURE WINDERS

portion to be placed in the bottom of the slot is toward you and the air-gap side of the coil is uppermost.

Armatures of the two-circuit type may be wound either progressive or retrogressive. A progressive wave of two-circuit winding is one where the throw of the coil lead is one-half a commutator bar greater than half way around the commutator. For example, with 135 commutator bars, a progressive winding has a coil throw of (135 — 1) ÷ 2 = 67 bars or 1 and 69. A retrogressive winding has a coil throw of (135 — 1) ÷ 2 = 67 bars or 1 and 68.

The wave or two-circuit windings always require an odd number of commutator bars. When an even number of coils per slot are used there will always be an idle, or dead, lead. When an odd number of coils per slot are used and there are an even number of slots on the armature there will always be an idle, or dead, lead. When the number of coils per slot is odd and there are an odd number of slots on the armature, there will never be an idle, or dead, coil. The alignment of the armature slots or teeth of the core with respect to the commutator mica or bar is as follows:

(1) With the coil throw even and the lead throw even, the center line of the tooth will line up with the center line of the mica.

(2) With the coil throw odd and the lead throw odd, the center line of the slot will line up with the center line of the bar.

(3) With the coil throw even and the lead throw odd, the center line of the tooth will line up with the center line of the bar.

(4) With the coil throw odd and the lead throw even, the center line of the slot will line up with the center line of the mica.

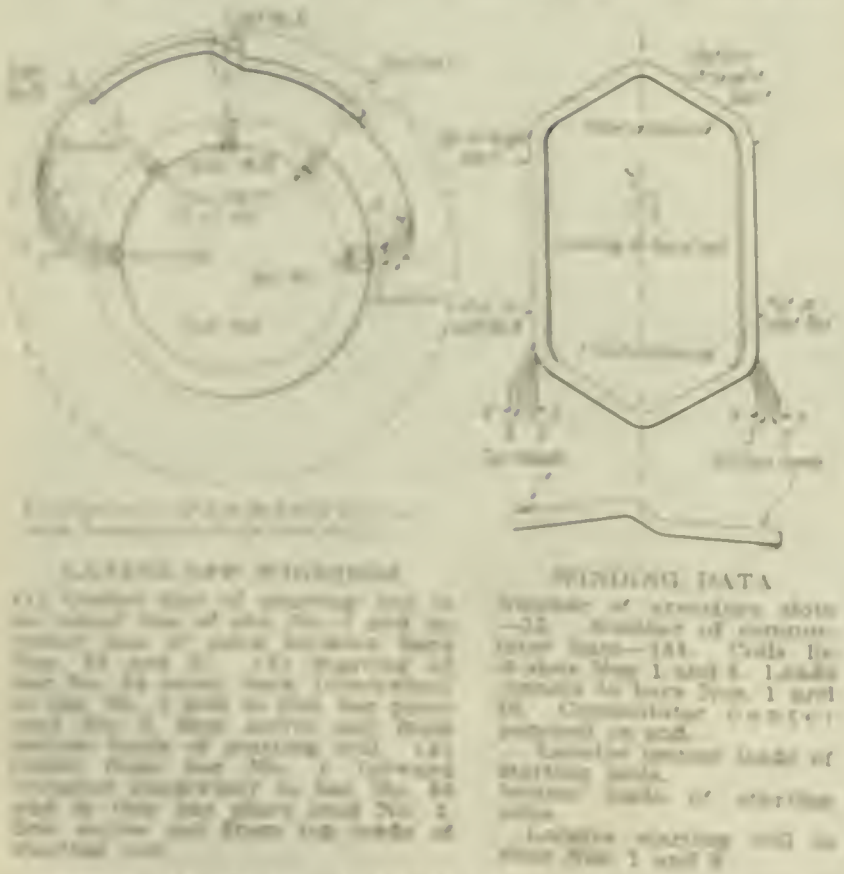

FIG. 3—ANOTHER DIAGRAM AND OTHER DATA FOR ARMATURE WINDERS

Sizes and Uses of British Anthracite

IN HIS little book on "Anthracite and the Anthracite Industry" A. Leonard Summers states that the recognized British standard sizes of anthracite are:

Selected large, for malting, hop drying and horticultural purposes.

Screened large, for export to crush to sized coals.

Machine-made cobbles (2½ in. to 4 in.), for central heating apparatus, Dowson and pressure gas plants, household and various purposes.

Machine-made "French" nuts (1¾ in. to 2½ in.), for practically the same purposes as cobbles and for open grates and large stoves.

Machine-made and washed stove nuts (1 to 1¾ in.), for suction gas plants and the majority of domestic stoves.

Machine-made and washed "pea-nuts" (½ in. to 1¼ in.), for "Economic" stoves and suction gas plants.

Machine-made and washed "beans" (½ in. to ⅞ in.), for suction gas plants and domestic stoves.

Machine-made and washed "peas" (¼ in. to ⅝ in.), for suction gas plants and steam raising.

Machine-made and washed grains (⅛ in. to ¼ in.), for specially constructed gas plants and under steam boilers with forced draft.

"Duff," the fine, small dust, for spelter and cement making, chiefly for mixing in small quantity with steam coals for making patent fuel, including boulets for domestic stoves and fires.

"Rubbly Culm," or the rough coal passed between longitudinal bars 1¼ in. apart, principally used for lime burning and steam raising.

Determines Ash in Coal with Milk Tester

A. M. Rodgers, a research worker in the School of Mines at the Pennsylvania State College, has devised a novel scheme for estimating rapidly the percentage of ash likely to be contained in a given sample of coal. By means of a centrifuge such as is used to test the proportion of cream in a given sample of milk, he has succeeded in making tests of coal in a few minutes whereas the previous method, which necessitated the burning of the coal, took nearly a day.

The coal to be tested is ground finely and poured into test tubes containing a liquid. When the tubes are whirled around rapidly by the centrifuge, the slate and sulphur go to the end of the tube and the combustible part of the coal is left near the top. Graduations, like those used in the milk and cream tester, show at once the proportion of waste in the coal.

Kentucky Mining Institute Discusses Loading Machine And Value of Business Associations of Coal Men

Suggested That Loading Machine Be Shifted by Locomotive and That Conveyor Be Made Telescopic, So That Loading Boom Before Operating Can Be Extended and Load Two Cars Without a Shift

THAT when properly managed the coal-loading machine has great possibilities is clear from the statement made by N. G. Alford at the meeting of the Kentucky Mining Institute, at the Seelbach Hotel, Louisville, Ky., on Nov. 3. He stated that the Pocahontas Fuel Co. had loaded with three machines 1,500 tons in one day with a force of men somewhere between twenty-seven and thirty-five, including those actually operating the loaders.

Brisk and businesslike was the meeting of the institute, which did not conclude till nearly midnight of the day of meeting. It had been intended to extend it until the following day, but at the request of some of the members who could not stay so long it was crowded into a single day and the report of the committee on the "Preparation of Coal" was omitted, as none of the members of that committee was at hand to read or discuss it.

The report of the committee on "Coal-Mining Machinery" was delivered by Alphonse F. Brosky, of Pittsburgh. As the subject seemed too large for a single session, the paper was limited in scope to mechanical coal-loading machinery and how it might be used to the greatest advantage. Interest was added to the paper by a number of lantern slides showing the different types of mechanical loaders.

Work of Loading Shovel Is Incomplete

F. P. Wright, of Bevier, Ky., opened the discussion, remarking that he gathered from the paper that mechanical loaders were complicated and cumbersome, and had not been so greatly simplified that the operator would be justified in adopting them as standard equipment. He also said that in the loading of coal by mechanical means more daymen would have to be employed than were required in the actual operation of the machines; otherwise, how could the rooms be cleaned up, fallen posts be replaced, track be maintained, and the many other jobs executed that always accompany room mining?

In reply to Mr. Wright's first remark A. F. Brosky said that we never could hope to develop a loading machine that would have a flexibility approaching anywhere near that of the human loader, but that the loading machine is being made more and more adaptable to mining needs. For the greater part of coal handling, electric power is cheaper than man power. Without question a straight loading machine will never be constructed that can be operated without some of the coal being shoveled in the final clean-up. But if the employment of a few daymen will make unnecessary the services of a far larger number of contract men, the cost of loading per ton will be lowered.

N. G. Alford recited what had already been achieved in mechanical loading at one of the mines of the Pocahontas Fuel Co. His statements seemed to convince the operators present that mechanical loading was far from a complete failure. In one of that company's mines three loading machines are said to have loaded out 1,500 tons in one day. The number of men required was somewhere between twenty-seven and thirty-five, including those operating the loaders.

Asked whether the conditions at this mine favored mechanical loading, Mr. Alford replied that they were exceptionally favorable, the seam being approximately 8 ft. thick. Interrogated by Mr. Jenkins as to whether the coal was soft and the roof unusually strong, Mr. Alford replied in the affirmative. Mr. Cockburn substantiated these statements by saying that few places had more favorable conditions for mechanical loading.

Suitable Time to Talk Motor Standardization

Graham Bright, of the Westinghouse Electric & Manufacturing Co., cautioned designers and manufacturers of mechanical loaders to decide upon a type of motor, preferably standard, and to allot sufficient room before going far in the design of other features, thus saving the great expense of designing and constructing a motor of unusual size and type.

Questioned as to what had been done by his firm to bring out an "explosion-proof motor" he said the term as applied to a motor to be used in a gassy mine is a misnomer. The term "permissible" might be adopted more appropriately. At the present time the demand for such a motor would not justify any manufacturer in spending a large sum of money to develop it. A permissible motor for the driving of the pumps has been available for a period of 5 or 6 years. The design in the early type provided wire-gauze screens to prevent explosions of gas.

Making Electric Motors Explosion-Proof

The Bureau of Mines never would pass favorably on this type of protection, yet at no time and under no conditions could the operation of the motor be made to cause an explosion of the gaseous atmosphere by which the machine was surrounded. The new type of permissible motor is built heavy, with wide flanges. It does not prevent explosions within the motor, but such explosions will not injure it nor extend to the air outside.

On being asked by Mr. Alford as to the most effective means of transporting a loading machine from place to place, Mr. Bright stated that he believed that in most cases the addition of self-propelling mechanism was a mistake. The simpler the mechanical loader the better, and for that reason it might be wise to eliminate the self-propelling devices on the truck and use a locomotive to pull the machine from place to place, providing it could be arranged so as to have one always on hand when the machine had to be moved.

F. P. Wright said that as the self-propelling cutting machine was regarded as essential why should it be expected that the loading machine would be satisfactory

without danger of moving itself, but Mr. Bright replied that the conditions in the one case might be entirely different from those in the other.

To Mr. Bright's remark that the addition of a self-propelling device might add too much weight to certain classes of mechanical loaders Mr. Wright rejoined that to propel the machine the same motor might be used as is utilized in driving the conveyor and in actuating the other moving parts. Mr. Alford was of the opinion that much of the moving is needless and might be overcome by paying more attention to the working of places in sequence.

Mr. Brooky suggested that the time expended in the shifting of mine cars might be cut in two if the loading boom on the loader were lengthened so that cars could be loaded in trips of two cars instead of one at a time. It should be possible to design a telescoping scraper conveyor that would not add to the height of the machine. With this extended the first car could be pushed under the conveyor and the second car placed under the discharge of the loading boom. After the latter car was loaded the other car could be pulled out so as to spot it and loading would resume. Before the loading machine was moved the conveyor could be telescoped and thus be fitted for maneuvering out of one room into the next. Several mechanical engineers have already expressed it as their opinion that the mechanical details of such an arrangement could be worked out.

Right to Balance Evil with Good Times

J. F. Callbreath, secretary of the American Mining Congress, being present, was asked to address the institute. He defended the coal industry from the charge of profiteering indefinitely and added that the operator should not be prohibited from making such a profit during favorable periods as will afford him a fair interest on his investment, not only for the period of prosperity but also for the slack periods that precede and follow the brief period of good fortune.

Mr. Callbreath then outlined to the institute the aims of the Southern, or Dixie, division of the American Mining Congress, now in process of making. He referred especially to the effect of the growth of mining on the future of the South, declaring that although the metallic ores in the Southern states were not nearly so rich as those of the West, the additional costs of recovery in the first-mentioned states would be offset by the reduced charge for carrying the products to Eastern markets.

After the coon roosts Graham Bright read a paper, illustrated by lantern slides, on "Gathering Locomotives for Coal Mines." In his paper he spoke of the merits of all-rubber cable for gathering locomotives, digressing for a moment to record the experience of the Pittsburgh Coal Co. in that respect. According to A. B. Kiser, chief electrical engineer of that company, the superintendents assert that all-rubber cable will outlive four to six of the braided cables. The men are not afraid to handle it, for when it is used the danger from shock is reduced to a minimum.

N. G. Alford started the discussion by asking Mr. Bright whether the principal use of the straight battery locomotive was in pulling coal from thin seams, where the cost of making headroom for any other type of locomotive would be prohibitive. Mr. Bright replied that approximately 50 per cent of all the straight storage batteries in use are found in thin seams.

Mr. Wright queried whether some new type of locomotive, the design of which would constitute a radical departure from those in common use, was under consideration. In reply Mr. Bright said that a caterpillar locomotive is now being developed.

Asked by Mr. Alford regarding the inherent operating difficulties in dynamic braking Mr. Bright replied that before adopting that principle for a locomotive one should make sure that the duty of the latter will be such as will permit of the economic use of a plan of that sort.

J. W. Reed, of the Consolidation Coal Co., wanted to know why in storage-battery locomotive design space was not allotted for an extra seat so as to accommodate a second rider. Mr. Bright informed him that such a provision was now being made. The space required, however, was obtained by sacrificing some of the room hitherto occupied by the storage battery.

Mr. Wright then asked the time-worn question as to when the mule and when the storage battery locomotive should be used. It was brought out that many mistakes have been made in the past, either because the operator chose the storage-battery locomotive for working conditions not suitable to it or else because the salesman taking orders for that type of locomotive foolishly led him to believe its adoption best. Where the working places are scattered the mule is just as economical as the locomotive. Mr. Wright finds that one mule will gather about 50 cars in a shift. Graham Bright said that under favorable conditions the locomotive should replace three or four mules and one or two drivers. He added, however, that figures of this nature are almost of no use to the other fellow, as blind statements without a knowledge of conditions of working mean little.

The second paper of the afternoon was entitled "What Good Roads Mean to Mining Districts," and was delivered by C. D. Franks, of Indianapolis, Ind. The change from mining to road making seemed to serve as a relaxation and to be appreciated by the institute.

Railroads Should Balance Car Borrowings

J. M. Dewberry, general coal and coke agent of the Louisville & Nashville R.R., spoke on "Present Coal-Traffic Problems and the Prospects for the Future." No discussion followed the reading of this paper. He regretted that the Interstate Commerce Act of 1920 is not enforced so as to compel a carrier to replace by another every railroad car that it borrows from the owning company. A few of the smaller railroads do not have enough rolling stock to handle the traffic which passes over their tracks. Consequently they attempt to hold cars that pass over their roads.

He condemned openly the inflation of mine ratings. He did not, however, recommend that the rates on the Louisville & Nashville R.R. be lowered to normal unless a corresponding drop were provided all along the line and on other roads. Orders for cars in the aggregate on this road are about 100 per cent in excess of the possible output from the mines which it serves.

After the committee reports had been read, Prof. Norwood, of the State University of Kentucky, read the constitution that had been prepared for the institute's action. C. J. Neekamp's paper on "How to Make an Operators' Association of Most Value" followed.

Mr. Butler said that many of the operators were lax in fulfilling their obligations to their association and lost interest during those periods when they are prospering and having no trouble. That is entirely wrong.

They should be "on their toes" at all times. He added that the operators must avail themselves fully of the publicity that was theirs for the asking. During the rail and coal strikes last summer the public made it apparent that they considered the main issue was the refusal of the miners and the operators to get together. If the operators had resorted to publicity the impression would not have entered the public mind.

Mr. Jenkins, vice-president of the West Kentucky Coal Co., maintained that the operators' side of the question should get at least as much publicity as that of the miners.

F. P. Wright well expressed his belief as to what an association of this kind should be when he said: "There is no better example of association, co-operation or co-ordination than the United Mine Workers." The members of that organization are loyal one to the other and to their society as a whole; nor do they at any time fail to give their leader their hearty support. He compared the operators to a team of horses pulling two ways.

The small operators always hesitate about coming into the operators' association, believing that it is controlled by the larger companies for their exclusive advantage. This is an erroneous idea, Mr. Wright said, as they may derive as much from it as the big fellow. It is the little company that really sets the prices, so why should he not come into the association?

He reiterated what was said by those who spoke before him on the need of publicity. Newspapermen come to the meetings of the operators and ask for information. Usually they are told "nothing doing." As they were sent for the purpose of getting information and are refused it by the operator, in self-defense they get whatever news they can possibly gather, regardless of the source, and then draw on their imagination. The coal industry should tell the public all about its business. There is no secret about it. Mr. Wright concluded by saying that the industry was up for trial before a one-sided tribunal and that it behooved the operator to make it two-sided by more co-operation and membership in the operators' associations and by more publicity.

Mr. Calbreath advocated publicity as a means of achieving a just settlement. This the coal operators have not yet succeeded in setting in operation. The public still believes, as a whole, that the operator gets most of the high price of coal whenever prices soar.

In the election of officers that followed this discussion Prof. T. J. Barr was elected president of the institute for the coming year, and Mrs. Elizabeth C. Rogers was again chosen as secretary-treasurer. It was almost midnight when the meeting, having completed its business, finally was adjourned.

North Carolina Again Among Coal States

By Bion H. Butler
Southern Pines, N. C.

THE Carolina Coal Co., of Southern Pines, N. C., has opened an interesting coal field in the North Carolina Triassic basin of Chatham County, not far from Sanford. It gives all promise of being an important addition to the power supply of that rapidly developing state. The development of the Carolina company includes a slope driven on a 27-deg. pitch 800 ft. into the bed, where it begins a series of headings and workings in a seam of excellent high-volatile coal about 4 ft. thick. Assays of the coal made by various agencies show a quality comparable with the best coals of Pennsylvania—low ash, low sulphur, high heating power and freedom from parting and impurities.

This field is by no means a new one, for before the Civil War the Egypt mine, two miles distant from the Carolina company's new mine, was operated by a shaft that had been sunk into the same coal seam. But the Egypt mine was at that time far from any market that needed coal in any quantity, and transportation consisted of an occasional wagon. Later a railroad was built into Egypt, but still the call for coal was slight and the method of operation was not very practical. An explosion ultimately settled the fate of the property. Later it was reopened, and it is now producing coal, with the prospect that it will become a valuable property under modern methods and facilities.

The Carolina Coal Co., with J. R. McQueen president, C. M. Reeves, general manager, Howard N. Butler superintendent, after extended investigation of the Deep River coal basin obtained 1,200 acres of land and drilled it with core drills, determining their deposit, and then proceeded to sink their slope and open a mine. They have about 3,000 ft. of underground workings exploring the coal, which runs regular, with hard sandstone roof and but little water. At the Carolina and the Cumnock mines about fifteen to twenty cars of coal are going out weekly now, with plans for increasing that as fast as conditions at the bottom will permit. The Carolina company's mine is planned for a daily capacity of 1,000 tons when fully developed.

The company has several thousand acres of additional land in reserve under option or lease or through the ownership of the stockholders and expects to develop further acreage as soon as the present property is brought into its intended activity.

The Deep River coal basin is a limited field in the Triassic rocks much higher up in the geological measures than the coals of the Carboniferous, but the coal appears to be identical with that of the lower formation. Three or four beds are present, only one of which will be worked by the Carolina company at the present time.

At the present time a geological survey is in progress under the management of K. K. Kimball and Maurice Campbell, of the U. S. Geological Survey. A preliminary survey a few weeks ago brought out such a favorable report that it was decided at Washington to make a thorough study of the coal basin that this coal deposit might be brought to the notice of the country and its resources made available for the expanding industries of the state.

North Carolina is fast becoming a prominent manufacturing state, being second to Massachusetts alone in the amount of cotton spun and foremost of all the states in the number of cotton mills. It is the leading tobacco manufacturing state of the Union and is close to the top in the production of furniture. All this takes power. An advantage which the Deep River basin has is that it is two or three hundred miles from competing coal and will have the inside track in its market.

The mines are seven miles out from Sanford near the village of Cumnock, on the Southern and Norfolk Southern railroads. It is believed the field will ultimately develop a capacity of several thousand tons daily, which will find a market within a limited radius.

Testing Materials Society Defines Coke

IN ORDER to standardize the methods of testing coke and to give it a nomenclature which will be of nation-wide acceptance the Society for Testing Materials in its annual volume of tentative standards has included a chapter entitled "Tentative Definitions of Terms Relating to Coke." It defines coke, beehive coke, byproduct coke and gashouse coke.

Foundry coke from beehive ovens it designates as coke which is physically and chemically suitable for use in foundry cupola practice. It may be either 72- or 48-hour coke. The principal difference between the two is the greater size of the 72-hour coke, due to thicker coal beds employed in its preparation. The breeze, or fine coke—smaller than approximately ½ in.—is forked or screened out.

Foundry coke from byproduct ovens is coke that is physically and chemically suitable for foundry cupola practice and which passes over a screening device having approximately 2½-in. openings. It is not produced in any standard coking time.

Furnace coke from beehive ovens is coke that is physically and chemically suitable for the reduction of iron ore in blast furnaces. The breeze smaller than approximately ½ in., as in foundry coke from the same source, is forked or screened out. The usual coking time is four 48-hour charges and two 72-hour charges.

Furnace coke from byproduct ovens is coke that is physically and chemically suitable for the reduction of iron ore in blast furnaces and which passes over a screening device with openings varying from ¾ to 1½ in., depending on local conditions at different plants. It is not produced in any standard coking time.

Domestic coke is coke of the smaller screened sizes, below approximately 2½ in., suitable for use in domestic stoves, heaters, etc. The standard sizes are quite generally sold under the names given in the table and the screened sizes are average, although locally varied somewhat.

SIZES OF DOMESTIC COKE

Name	Size of Screens	
	Passing	Retained on
Egg	2½ in.	1¾ in.
Nut	1¾ in.	1¼ in.
Pea	1 in.	¾ in.
Breeze	¾ in.	½ in.

The chapter also defines for purposes of analysis dry coke, moisture, ash, volatile matter and fixed carbon. Volatile matter is described as that part of coal or coke which on heating is driven off in the form of tars and gases and is determined as the percentage loss in weight, less the percentage of moisture, sustained on heating coke in a covered platinum crucible for 7 minutes at a temperature of 950 deg. C.

Obviously coal should be omitted in the first part of this definition if it is not to be classed in the last part. Certainly all the volatile matter driven off dry coal does not consist of tars and gases unless steam is regarded as a gas, which indeed it is, but it would seem that the words were put in purposely to exclude steam, for if it does not exclude it these words are entirely useless. The definition is faulty and misleading.

Dry coke is defined as coke which has been dried to constant weight at temperatures not less than 104 deg. C. nor more than 200 deg. C. in the case of lump coal and between 104 deg. C. and 110 deg. C. in the case of 60-mesh coke. This also is not as specific as it with advantage might be made. Why leave a range as great as that between 104 and 200 deg. C.?

Additions, Removals and Changes in List of Permissible Explosives

BY S. P. HOWELL*

A COMPLETE list of permissible explosives tested prior to March 15, 1922, was published in Bureau of Mines Technical Paper 307, entitled "Permissible Mining Equipment, Apparatus and Explosives, Approved Prior to March 15, 1922," by S. P. Howell, L. C. Ilsley, D. J. Parker and A. C. Fieldner. Since that date up to and including Sept. 30, 1922, the following additions, removals and changes have been made:

ADDITIONS TO LIST OF PERMISSIBLE EXPLOSIVES FROM MARCH 15 TO SEPT. 30, 1922

Brand	Weight of 1¼ x 8 in. cartridge, Grams	Smallest permissible diameter, Inches	Unit Deflective Charge, Grams	Rate of Detonation in 14-in. Diameter Cartridge When Fired With a Detonator, Preferably Electric of Not Less Efficiency Than No. 6, Ft per Second	Manufacturer
Apache Coal Powder A	137	1¼	222	11,710	Apache Powder Co., Benson, Ariz.
Apache Coal Powder B	158	1¼	241	8,210	Apache Powder Co., Benson, Ariz.
Black Diamond No. 7	172	¾	222	10,780	Ill. Powder Manufacturing Co., St. Louis, Mo.
Dunbel L. F.	147	¾	225	12,440	E. I. duPont de-Nemours & Co., Wil., Del.
Grasselli 2 L.F.	142	¾	221	10,870	Grasselli Powder Co. Cleveland, O.
Grasselli 5 L.F.	156	¾	223	7,680	Grasselli Powder Co. Cleveland, O.
Grasselli 6 L.F.	162	¾	218	9,210	Grasselli Powder Co. Cleveland, O.
Monobel No. 1 L.F.	176	¾	231	12,860	E. I. duPont de-Nemours & Co., Wil., Del.
Monobel No. 2 L.F.[3]	175	¾	252	10,760	E. I. duPont de-Nemours & Co., Wil., Del.
Monobel No. 4 L.F.	175	¾	252	10,760	E. I. duPont de-Nemours & Co., Wil., Del.
Monobel No. 5 L.F.	170	¾	249	6,400	E. I. duPont de-Nemours & Co., Wil., Del.
Monobel No. 6 L.F.	176	¾	220	13,630	E. I. duPont de-Nemours & Co., Wil., Del.
Monobel No. 9	137	¾	222	7,310	E. I. duPont de-Nemours & Co., Wil., Del.
Union D L.F.[1]	163	¾	223	11,100	Union Explosives Co. Clarksburg, W. Va.
Union E L.F.[2]	163	¾	233	10,220	Union Explosives Co. Clarksburg, W. Va.

[1] Same as Pa. Coal Powder B L.F. [2] Same as Pa. Coal Powder C L.F. [3] Same as Monobel No. 4 L.F.

In addition to the foregoing additions, the following changes have been made: Aetna coal powder A changed to Hercules coal powder A; Aetna coal powder AA to Hercules coal powder AA; Aetna coal powder B to Hercules coal powder B; Aetna coal powder C to Hercules coal powder C; Aetna coal powder 2 to Hercules coal powder 2; the smallest permissible diameter of Black Diamond No. 7 has been changed to ¾ in.; of Bituminite 5 to 1 in.; Grasselli Nos. 1, 5 and 6 all changed to ¾ in.

The following explosives have been withdrawn from the list of permissibles: Bituminite 8 L.F., Coal Special 1-A, Collier 6, Franklinite 1, Nitro low-flame Nos. 1 and 2, Big Red No. 6, L.F., DuPont permissible No. 1, Mine-ite A, Tunnelite No. 4, and Tunnelite No. 8.

*Explosives engineer, Bureau of Mines.

Problems of Operating Men

Edited by James T. Beard

Inspiring Self-Confidence in Miners by Example

All Have Much to Learn From Others—Gaining the Confidence of Men Is the First Essential Quality of a Good Foreman—Confidence Insures Trust and Obedience

EXAMPLE goes farther than precept. Nothing will inspire confidence in men for their boss quicker than the show of a like confidence on his part in them. Every man has much to learn from his fellows; and men are quick observers of the feelings of their boss toward them, and not slow to follow his example.

This was the thought that I attempted to express in my letter, a few weeks ago (*Coal Age*, Aug. 24, p. 290), in regard to gaining the confidence of men, which I see, from the letter of John Rose, page 636 of the last issue of *Coal Age*, was not fully understood.

It has always been a pleasure to read the letters of Mr. Rose, as I know that men of his stamp have been longer in the mining game than myself. I am a comparatively young man, having been mining coal about eleven years; but I am in the game for all it is worth and am always ready to gain new ideas from the many writers of experience in *Coal Age*.

In his excellent letter, Mr. Rose's main thought seems to be to inspire men to have confidence in themselves. I am sorry that he should have misread my letter enough to think that I had any other thought than that of inspiring men to act intelligently, by giving them safe instructions.

Confidence in a Foreman Inspires Obedience to His Orders

The first essential of a good foreman is to gain the confidence of his men. Until he has done that, his instructions to them, regarding safe practices and economical methods, will fall on deaf ears. On the other hand, men will listen and give heed to what a man says in whom they have confidence. That was my idea in writing that first letter.

The instance I then cited was that of overhearing the conversation of two miners, in the room adjoining my own. Miner No. 1 was telling Miner No. 2 that he (No. 2) was doing unnecessary work in setting some timbers back along the road in his place. The reply was, "Well, George, my boss told me to set them while I had time between cars. He said it would make my place safer and the work easier for drawing back the pillars, and he knows."

Here was a man who had confidence in his boss; and that confidence enabled him to profit by the instructions given him by an experienced foreman who foresaw that the setting of a few timbers, in the miner's spare time, would greatly assist the work of drawing back the pillars, later, when that had to be done.

Miner and Foreman Disagree

While I am writing, let me give an another instance when there was not the same confidence on the part of the miner in his boss. The illustration will also serve to show the danger that may result from an indifferent attitude on the part of a foreman who is willing to compromise his instructions, owing to objections offered by the miner.

Awhile ago, I chanced to be in a man's place when the assistant foreman came in. Observing a loose piece of slate that had no timber to support it, the assistant foreman said to the miner, "John, put up a post here and do it now." The reply was, "I can't stand a post there, as it will not give me room to work." "Well," said the foreman, "take the slate down then."

The miner then explained that taking down the slate would mean the taking out of other timbers on which it rested and would require much extra work. The result was that the assistant foreman compromised what he knew to be a dangerous proposition and told the miner to stand a temporary post there, until he could get away from the place.

Compromising Evident Danger Unsafe Plan to Adopt

This satisfied the miner since, as he said after the assistant had gone, he could stick up anything there for the time being and it would be all right with the boss. To my mind, this assistant foreman made a great mistake when he told the man to set a timber temporarily. He should have realized that the only safe plan to pursue was to take the loose piece down and avoid a probably fatal accident. My plan is, never defer dangerous work, but give it immediate attention.

What a foreman needs to impress on the minds of his men is to always do things in the right way. A foreman must show his men, the first time, and watch them, afterwards, to see that they understand how to do it themselves. Then, tell him it is good; but show him where he can improve by making some changes another time.

Encouragement goes a great ways in instructing men. Encouraging words show a foreman's confidence in the man's ability to perform work in the right way; and confidence, on the part of the foreman, is the first step in gaining the confidence of his men and securing their co-operation in making their work safe.

By teaching men to guard against present dangers, which are clearly seen and realized, they learn to accept and obey instructions that are designed to avert dangers, which may arise in the future. Future dangers are not so clearly discerned by the miner of less experience. Only in this way can we expect to establish self-confidence in men, by training them to foresee danger and play safe. In closing, let me thank Mr. Rose for his good letter, every sentiment of which I fully endorse.

Thorpe, W. Va. U. S. Coal & Coke Co.

Gathering Cars With Reel Cable

Practical difficulties encountered in the use of long cables in gathering cars —Expense of frequent renewals of worn cables—Danger of sparking by cable coming in contact with rails

THE inquiry that appeared in Coal *Age*, Oct. 12, p. 594, regarding the use of single and double cables for gathering cars at the working face, recalls to my mind experiences in the use of reel cables for gathering cars.

In common with others, we had long followed the practice of running out the cable, often to its full length, to enable the locomotive to reach the cars standing at the face of headings and rooms. It was some time before we learned by experience the difficulties and dangers attending the use of long cables for that purpose.

In the first place, there was considerable delay in unreeling and reeling the cables; but that was not the only and by no means the least objection to the continued use of long cables. The constant wear and tear shortened the life of the cable and required frequent renewals, which made the practice very expensive.

Of still greater importance, however, was the danger due to the sparking of the wire, which invariably occurred when hooking the cable to the trolley line. Again, it was impossible to avoid the cable's coming in contact with the rails as it stretched along the track. This was another cause of much sparking at points where the insulation had

[illegible] all so that the wire was exposed.

At one of our mines, we were using a rail for a distance of between three and four hundred feet, to pull cars out of those places that were running to the dip. Here it became necessary to change the rails every six weeks and the danger of fireworks kept these places lighted up continuously.

One suggestion finally taught us that, having one wire a rail, while all right on a straight road, is expensive and dangerous where the roads are crooked and the grades not uniform. We concluded that it was safer practice to keep the trolley wire within 50 ft. of the working face, and the result has been a saving of both time and repairs.

In the instance mentioned where the two places were running to the dip, a little room-hoist was installed, and, using a one-half inch steel rope, the cars were pulled out of those places easily and quickly. By this means, a trip was gathered in the same time that the locomotive was hauling a previous trip to the foot of the shaft; and there was no more trouble with the sparking of wires.

Before closing, let me mention one point that may be of interest to many readers. In order to avoid the frequent splicing of the trolley wire, we have adopted the scheme of not cutting the wire at the dead end. Instead, we have found no difficulty in carrying along a spool of wire holding, say 1,000 ft. The spool was hinged in a convenient place and moved along as often as it was desired to make an extension of the main trolley.

Notwithstanding the fact that the mining law, in some states, limits the distance of the dead-end of a trolley line from the working face, it is my belief that there is more danger in the use of long cables, than would result from a closer approach of the trolley wire to the working face. In other words, such a remedy is worse than the disease.

Pittsburg, Pa. RICHARD HOWDEN.

Why Accidents in American Mines Do Not Decrease

On every hand is evidence of efforts made to promote safety—Chief topic of research among mine officials and at miners' meetings—Comparing English and American mine fatalities

THAT this is a good age for safety-first movements in every branch of industry, is apparent whichever way we turn. On every hand we find evidences of the many efforts that are continually being put forth to promote safety. I notice that the more expensive of mine's vehicles, in *Coal Age*, do not pass by this subject of safety, always bringing a host of letters in reply.

The value of any public worker, today, finds numerous printed notices giving the warning of dangers to be avoided. The same is true when we enter a large mine. The solid bulletin boards display pictures showing both how acci-

dents may happen and how they can be avoided.

It would seem that if these numerous warnings and signs of danger were given the slightest heed by workmen, accidents would be almost impossible and soon become an unheard of occurrence. Among mining officials, the avoidance of accidents in and around mines is almost sure to form the chief topic of conversation when they meet; and safety methods and appliances are the principal subjects discussed at their regular weekly and monthly meetings.

Again, our compensation-insurance inspectors continually remind us of what must be done, or what dangerous practices must cease, if the mine rating is not to be increased. Many of the items in the inspector's Book of Standards, by which the mine rating is determined, appear so insignificant as to hardly attract the notice of the average mining man.

With all these safeguards and daily reminders, however, we may well ask ourselves the question: Is our accident list growing any less? To be honest with ourselves, we must admit that the results are not in keeping with all the efforts put forth in the interest of safety.

Fatality Rate in the United States Greater Than in England

Many comparisons between English and American mines have been made in *Coal Age*, from time to time. These comparisons are fair and just, as the mining laws of the two countries are very similar. Owing to the generally deeper mines of England increasing the dangers of mining the coal, such comparisons should be more favorable to the mines of this country.

Notwithstanding the fact, however, that general conditions favor American mining, what do we find? In the last report giving the fatalities in American mines, I see the number of men killed is between three and four, for every thousand men employed. For the same period in England, the report gives less than one fatal accident, per thousand men employed.

There must be a reason for this great difference in mining fatalities between the two countries. In my opinion, it is to be found in the fact that English laws are *made to be kept*, while in this country violators of the law too often go unpunished. By some hook or crook the guilty person, here, expects to escape the prescribed penalty for his act.

Violations of Mines Regulation Act Quickly Punished

To illustrate this truth, permit me to cite two instances of violations of the laws, there and here. On a certain occasion, in a mine in England, an overman, inspecting some loaded cars on the shaft bottom, found a lump of coal having a drill-hole partly filled with coal slack that had been used in tamping the hole.

The shot had evidently been tamped in direct violation of the Coal Mines Regulation Act, that requires the use of clay for that purpose. Taking the lump of coal from the car and laying it aside, the overman went into the mine for the man and, facing him with the evidence of his guilt, had him arrested at once.

The man expected no leniency and was, in no way, disappointed when he received the full penalty for his act, under the law, both the overman and the manager appearing as his prosecutors. Compare this summary punishment of a violator of the mine law in England, with the result of a similar violation of the law in this country.

Mine Officials Plead Leniency for Men Who Violated Code

Not long ago, at a certain mine where I am acquainted, several men were found to have matches in their possession when at work in a gaseous section where safety lamps were in use. Besides the matches the searchers found pipes and tobacco on the men. Carrying these articles into a mine generating gas violated the code and information was conveyed to the state mine inspector, who had the men arrested.

When given a hearing, however, the mine superintendent appeared in court and pleaded with the judge for the exercise of clemency toward the men, claiming it was their first (?) offense. The result was that the men were let off with a simple warning by the court and no fine or other punishment was imposed on them. The plea of the superintendent was a mistaken kindness and the action of the court does not speak well for American justice.

Classifying Coal Mines

There is another difference between English and American practice regarding mines generating gas. In England, mines are not classified as "gaseous" and "non-gaseous." A clause in the Mines Regulation Act reads somewhat as follows: "All places where men shall work or pass, shall be examined by a competent person." It does not matter whether two men, or ten men, or fifty, are working in the mine; nor whether they are in ten yards, or a mile, the law requires the examination of the working places by a competent person.

In this country, our laws lay far too much stress on classifying a mine as "gaseous" or "non-gaseous." The finding of a little gas in a place may be sufficient to cause the mine to be classed as a "gassy mine," and, as a result, its management must shoulder the expense of employing shotfirers, firebosses and first-grade certified men as mine officials.

It can be readily seen that, under this phase of the law, an unjust difference may be established between two mines, in the same field and operating practically under like conditions, except that a small quantity of gas found in a place necessitated this arbitrary classification, under the law.

It must not be thought that I would do away with our firebosses and shotfirers. That is not the case. My point is that the gas danger is over-esti-

mated in our laws, in thus classifying mines. Statistics show that more than 50 per cent of our mine accidents result from falling roof and coal, while one-tenth of this percentage of accidents are due to gas. Let us, then, seek a more equable basis that will work no unnecessary burden on any mine; but let every mine be examined for the dangers that are present.

Indiana, Pa. THOMAS HOGARTH.

Why Install a Booster Fan

Need of installing a booster fan shows bad mine management — Practical means of increasing the circulation in a mine—No place for a ventilator underground.

IT was with much surprise that I read the inquiry of a mine manager in Wyoming, who was contemplating the installation of a booster fan in his mine and wished to know the most advantageous point for its location. From the proposition presented, it seems evident that the intention was to install the booster as a unit in the ventilating system of the mine.

In addition to what has already been said in the reply to this inquiry, I may be permitted to add a few words endorsing the position taken by the editor. In my opinion, the installation of a booster fan within the workings of a mine is a bad mistake. Indeed, the need of making such a move is a sign of poor mine management on the part of the officials in charge.

NO INCREASE IN THE CIRCULATION

Observation and experience show that a booster fan, installed in a mine, does not increase the quantity of air in circulation. As has often been explained in the columns of *Coal Age*, the only effect of a booster is to rush the air past leaky stoppings and doors; and this can only be recommended as a temporary means of improving the circulation at the working face, in a section of the mine about to be abandoned.

No practical mining man will ever prescribe the installation of a booster fan as a unit in mine ventilation. There are other means of improving the circulation at the working faces that are safer, more efficient and in line with good management.

In the first place, clean up all airways and remove every obstruction to the free passage of the air current throughout the mine. Wherever practical, straighten the course of the air and avoid sharp bends in the airways. Repair all leaky stoppings and doors, and enlarge breakthroughs where the area is less than that of the airway.

At times, it may even become necessary to sink an air shaft at some point nearer the working faces, which will greatly shorten the distance the air must travel; and a larger quantity of air will then be circulated with less power. Frequently, in the development of a mine, this is the only practical remedy to improve the circulation.

To my way of thinking, in nine cases out of ten, the installation of a booster fan, at some point near the working face, is merely a bluff on the part of the company to make the miners think that everything possible is being done to give them good air. In other words, the miner is hoodwinked and the management avoids, for a time, the making of the necessary repairs of poor stoppings and doors.

In a few words, let me say that the situation should seldom arise that will warrant the installation of a booster fan in a mine. The mine manager should have the practical experience and skill, in the development of the mine, that such a condition will be avoided where it will become necessary to resort to the use of a booster fan.

Let it be understood, once and for all, that an underground location of any essential factor in creating the air current in a mine is not to be considered. All such means must be placed on the surface where they are accessible in any emergency that may arise.

Wilder, Tenn. OSCAR H. JONES.

Inquiries Of General Interest

Making Blueprint Paper and Blueprinting

Formula for Sensitizing Paper—Action of Sunlight to Change Chemical Salts—Washing Out Unchanged Salts Develops Print — Coloring Prints

WILL you kindly explain, through the columns of *Coal Age*, the process of making blueprint paper and give me any information needed regarding the coloring of blueprints to show distinctive features?

Saskatchewan, Canada. MINING ENGINEER.

In the making of blueprint paper, a good quality of rag paper should be selected, as this gives whiter lines, in the blueprinting, than paper made of wood pulp and is more readily handled in the process of sensitizing. Cloth specially prepared, or paper backed with cloth, is often used when the blueprints are required to withstand much handling.

The sensitizing of the paper must be accomplished in a dark room or, at least, where the light is greatly subdued. Two solutions are first prepared as follows: Solution 1 consists of one part by weight of ammonia-citrate of iron, dissolved in five parts of water. Solution 2 is made by dissolving one part by weight of potassium ferricyanide, commonly called red prussiate of potash, in five parts of water. These solutions must be kept separate in stoppered bottles until they are required for use.

In sensitizing, the paper is laid flat on a table. The two solutions are then mixed in equal parts, in the dark room where the work is performed, and the resulting mixture applied to the paper as uniformly as possible, using for that purpose a soft sponge and working quickly to avoid unequal warping of the paper. After applying the sensitizing solution, the paper is hung up to dry, in the dark room, and when thoroughly dry is stored in a dry dark place until wanted for use.

It is difficult to say just what reaction takes place under the influence of light, either sunlight or electric light, whereby the iron salt is rendered insoluble, forming the deep blue background when the print is washed following the exposure of the sensitized paper under the linen tracing to be copied. The action is complex, the previously soluble iron salt being probably reduced and forming an insoluble prussiate, which the presence of the citric acid can no longer prevent. Before the reduction of the iron to the lower oxide, the citric acid in the mixture prevents the precipitation of the iron by the ammonia; and this is the condition where the light has not penetrated and changed the salt beneath the dark lines of the tracing.

The time of the exposure of the sensitized paper beneath the tracing to be copied will depend on both the strength of the light and the age of the paper. In strong sunlight, not more than 3 or 4 min. is required when the paper is fresh. Fresh sensitized paper has a light pea green color. In time, however, this color changes gradually to a darker shade of green and finally to blue when the paper is old and no longer of any use. Also, the fresher the paper, the whiter will be the lines on the print after washing.

No time should be permitted to elapse between the exposure to the light and the washing process. It is a good plan to so submerge the paper as to cause the water to flow rapidly over its entire surface. Better results are generally obtained when the water is kept slightly agitated over the surface of the paper, by moving the fingers forward and backward through the water for a short time during the first moments of immersion. By this means, the dissolving action of the water is made more uniform.

It will sometimes happen that a print has been overexposed and, as a result, many of the finer lines appear to be almost obliterated. In that case, it is

possible to restore them, largely or completely, by pouring over the print a weak solution of the red prussiate of potash.

Print paper should always be used in washing the prints and the process must be continued long enough to completely remove the soluble salt and show every detail of the drawing in white lines on a dark blue background. The paper should then be removed from the tank and hung up where it will dry uniformly.

A blueprint always shrinks to some extent, depending on the quality of the paper. For this reason, it is customary to draw a scale on the original tracing. In reproduction on the blueprint will serve as a reference, where dimensions have not been indicated and must be scaled on a blueprint when in use out of the office.

It would seem unnecessary to add that the exposure of the sensitized paper to the light is made in a frame specially designed for that purpose. The paper is laid beneath the linen tracing to be copied and both are placed under the glass of the frame. It is important to lay the paper and tracing on some soft material that will keep them evenly pressed against the glass, in order to obtain a good impression of all the lines of the drawing, particularly the fine dimension lines.

Sometimes, instead of section lining, or other distinctive markings on the original tracing, coloring matter is used to symbolize what is wanted; or the same coloring may be made on the blueprint only. This can be done with a brush or by colored crayons, as desired. When the coloring is done on the original tracing, the blueprint will show a lighter tint than the background. The tinting on the original tracing with a brush must be carefully done, using a very dilute solution of the desired water color and applying it uniformly and quickly to avoid warping.

Examination Questions Answered

Mine Managers' Examination, Nova Scotia, 1922

(Selected Questions)

QUESTION—*What is the smallest percentage of gas that, in your opinion, can be detected by means of an ordinary safety lamp?*

ANSWER—The ability to detect small percentages of gas will depend largely upon the observer and the kind of lamp employed. In the use of a common Davy lamp, few firebosses are able to detect less than 2 or 2½ per cent of gas. On the other hand, a good fireboss, using a Wolf lamp, will be able to detect as low as 1 per cent of gas present in the air.

QUESTION—*What are the gases usually given off by a gob fire? Describe their properties.*

ANSWER—The gases given off by a gob fire will depend on the supply of air to the fire. In a plentiful supply of air carbon dioxide is produced, the combustion being then complete. More often, however, there is lack of air sufficient to produce complete combustion, in a gob fire; and the result is that carbon monoxide gas is produced, with some carbon dioxide.

Carbon dioxide is an extinctive gas, containing no available oxygen. The gas is not combustible and will not support life. When air is breathed containing carbon dioxide the effect is to produce headache, pains in the back and limbs, nausea and suffocation if the percentage of gas is sufficient.

Carbon monoxide is a poisonous gas, small percentages of this gas present in the air breathed, may produce instant death. The gas is combustible, burning with a pale blue nonluminous flame.

QUESTION—*How many horsepower will be required to raise 4,000 cu.ft. of water, per hour, from a mine 1,080 ft. deep?*

ANSWER—Taking the weight of water as 62.5 lb. per cu.ft., and assuming a water-end efficiency of the pump as 75 per cent, the power required, in this case, is

$$H = \frac{4{,}000 \times 62.5 \times 1{,}080}{0.75 \times 33{,}000} = 181.8 \text{ hp.}$$

QUESTION—*How much work is done in raising 300 tons of coal up an incline 2,700 ft. long and rising 1 ft. in 3, adding 40 per cent to the load, for the friction?*

ANSWER—Taking the rise as 1 ft. of vertical, in 3 ft. of inclined measurement, the total rise of this plane is 2,700 ÷ 3 = 900 ft. Then, adding 40 per cent to the load, to allow for friction, the total effective load is 300 × 1.40 = 420 tons. Therefore, the work performed in making this hoist is 420 × 2,000 × 900 = 756,000,000 *ft.-lb.*

QUESTION—(a) *How is the electric current generated before it is transmitted? (b) How is the transmitted electric power utilized?*

ANSWER—(a) A dynamo, operated by a steam engine or other source of power, is used to generate an electric current. The dynamo is then called a "generator."

(b) The transmitted electric current is made to pass through the coils of another dynamo, and the reaction that takes place, between the armatures and the commutator, causes the latter to revolve. In this case, the dynamo is called a "motor." The principle of action in a motor is exactly the reverse of that in a generator. While a generator converts mechanical power into electrical energy, a motor converts electrical energy into mechanical power.

QUESTION—(a) *How is electrical energy transmitted in a mine? (b) What three things should be carefully proportioned for the safe transmission of electrical energy?*

ANSWER—(a) Electrical energy is transmitted, from the generators to points in a mine where it is to be used, by means of a copper wire called a conductor.

(b) In transmitting electrical power, the size of the conducting wire, or amount of copper used, must be proportioned to the strength of the current, or amperage required, and the distance from the generator to where the power is applied. Using a larger wire, or more copper, the same current can be transmitted at a lower pressure, or voltage.

QUESTION—*Do you consider electricity, as a motive or lighting power, dangerous in mines producing explosive gases?*

ANSWER—Yes. In mines producing any considerable quantity of explosive gas, electrical installations should not be considered, as the presence of live wires makes possible the accidental ignition of gas and is a menace to safety.

QUESTION—*How would you proceed to remove a man in contact with a live wire?*

ANSWER—Of course, if a switch is close at hand shut off the current at once. Otherwise, make no delay; but, standing on a dry board or dry ground, drag the man from the wire by seizing his clothing if dry. If a pole is at hand it may be possible to push the man off from the wire. It is sometimes possible to seize an ax and cut the wire by one quick blow on the side of the victim toward the power. Again, an iron bar or drill may be thrown across the wire, on the side toward the power, for the purpose of short-circuiting some of the current.

QUESTION—*What are the most common dangers that come from the use of electricity in mines; and what methods would you employ to prevent accidents?*

ANSWER—When an electric installation is not properly made there is danger of men and animals coming in contact with unprotected wires; or fire may occur by the ignition of gas, or combustible material, owing to the sparking of live wires, blowing out of fuses, etc. To prevent accidents of this nature, all electrical installations should be made by competent electricians thoroughly familiar with mining conditions. Protect all wires where men or animals may come in contact with the wire.

"Competitive-Field" Wage-Making Plan Likely to Be Revived at Second Miner-Operator Conference

Some form of the old Central Competitive Field plan of wage making for the coal-mining industry of this country is likely to be re-established this winter. A fairly well-defined trend in that direction was the nearest approach to concrete accomplishment at the joint conference of operators and miners from fifteen districts held in Chicago last week. The conference, whose first futile day was reported in these columns last week, spent four days at the job of trying to design new wage-making machinery for the future. Then it adjourned to reconvene Dec. 6 in Chicago. For four days the miners sat back smugly confident, waiting for the operators to agree upon something. For four days the operators wrangled among themselves, arguing everything from the sublime to the ridiculous, the men from the "outlying districts" fighting for a direct voice in future wage negotiations and the men from the four states of the old Central Competitive Field—western Pennsylvania, Ohio, Indiana and Illinois—resisting, though divided in their own ranks. They reached no final agreement on any plan. But on the evening of the fourth day—Friday, Nov. 17—when it was evident that nothing better could be done, the conference adjourned until Dec. 6.

In the meantime the operators are discussing in their home regions a scheme of re-establishing some sort of "central competitive field" whose mine owners would discuss policy with men from the outlying districts and then send their own scale committee in to make an agreement with the union miners as of yore. It is by no means certain what regions would comprise this central field. Neither is it determined what groupings of "outlying districts" would be made. Various ideas along these lines are to be brought back to Chicago on Dec. 4, when the operators' half of the joint committee is expected to convene two days ahead of the main conference. Illinois operators, divided at least two ways on the question of entrance into a "central competitive field," will meet in Chicago, Friday, Nov. 24, in an effort to solidify the position of that state.

Thus the first session of the joint miner-operator conference on ways and means for future wage negotiations failed to set up machinery or even to design any; but it did do two other things. It gave the operators a chance to clear a good deal of argumentative ground and it gave enough promise of working out a plan in December so that the miners' union cannot aggravate the 1923 strike scare and thus hold up coal prices this winter by telling the public that the operators refused to do business with them.

Miners Look to Operators to Produce a Plan

From the beginning of the Chicago conference until the end the miners took the position that it was up to the operators to produce a new plan, and that until they did the old four-state method of wage agreement should be considered to be in effect. Both President John L. Lewis and Secretary-Treasurer William Green said the miners were there with open minds, hoping something constructive and acceptable would be conceived. They made it plain that the miners would consider any proposal that gave them some single authority among the operators with which to deal which would be sufficiently representative to fix a basis for the rest of the country.

Among the operators, argument started early on the question of effecting some kind of national basis of agreement. This was the main drive of the "outlying districts." Two definite plans were proposed, one by Harry N. Taylor, of Kansas City, Mo., and one by C. H. Jenkins, of Fairmont, W. Va. These two plans in various forms were debated for three days, their advocates offering many modifications, but all to little purpose.

The original Taylor plan, written by Mr. Taylor and by Commissioner W. L. A. Johnson of the Southwest Interstate Coal Operators' Association, would have created a joint national wage board to negotiate a basic wage scale for the whole country. Variations from this basic rate would be determined for the various districts on account of "economic, competitive or physical conditions." These various district rates would be termed the base rate plus or minus given percentages and would be fixed "under authority of the national conference and by mutual agreement between the miners and operators of the districts."

Courts of appeal to settle disputes and prevent strikes would be created also. A "joint executive board" for the whole country, composed of an equal number of miners and operators plus a non-partisan chairman of highest caliber, whose vote would break any tie, would be the "supreme court." Smaller joint district executive boards would function in each district or group of districts to consider all sorts of disputes which the existing local and district machinery could not settle.

The plan provided that after the "base rate plus or minus" wage scheme had worked at least six months, either miners or operators could appeal to the joint executive board for a readjustment of the base for their district, providing it could be shown "that the base rates existing in the adjacent or surrounding competitive territory have been either advanced or diminished equal to an amount of 10 per cent of such base rates." This was calculated to give union fields participating in the scheme a chance to gain protection against neighboring non-union competition.

National Features of Plan Attacked

The national base-rate feature and the national negotiation features of the plan were attacked at once, mainly by men in the old four-state competitive field. Various features of the appeal plan were criticised and it was apparent the miners thought the scheme smacked too much of arbitration. Mr. Taylor and Mr. Johnson made it plain, however, they were proposing only a general idea and stood ready to consider any modifications or additions that anybody had to suggest. They rewrote sections of the plan several times, in an attempt to modify the national feature and provide something approximating district autonomy. But there seemed no possibility of getting anything like a majority to support it.

Mr. Jenkins and the men of northern West Virginia pushed hard for their plan, which also was presented, they said, only as a general idea which could be molded to various forms. This plan in its original form would have set up a national labor organization of union operators to determine labor policy only and not to negotiate wage scales. This organization would fix in general terms the operators' policies with regard to the proportion of wage increases or decreases within all districts, changes in hours, minimum cases for district differentials, improved methods of mining, labor and production, and questions involving labor supply. It would supervise and enforce a new system of district zones, provide a channel of communication with governmental departments and the general public on labor matters, establish and maintain a general bureau of industrial relations to provide statistics and other data for negotiations and to disseminate information throughout the industry, and to set up both district and national appeal boards to settle disputes.

In further detail the West Virginia plan has more or less parallel to that from the Southwestern Interstate field. It called for a joint wage council of operators and miners to determine a base wage for the country, hours of labor and the duration of each periodic wage agreement. The operators' members on this council would be selected by a vote on a tonnage basis. Joint scale committees for each district would work out district differentials and working conditions for their districts. A joint national appeal board with a non-partisan chairman and with members chosen by districts would "decide all questions upon which the National Wage Council has been unable to agree."

The West Virginia men thought the country should be redistricted into eight regions, the I. Pennsylvania-

[illegible] Illinois, [illegible] Ohio, [illegible] Indiana; [illegible] (Southeast) Maryland, Virginia, Kentucky, Tennessee and Alabama; [illegible] (Southwest) Missouri, Arkansas, Kansas, Oklahoma, Texas and New Mexico; [illegible] (Northwest) Michigan, North Dakota, Iowa, Colorado, Wyoming, Utah, Montana and Washington.

There was much hesitancy among operators to debate theory that finally all the suggested plans were referred to an operators' committee of six to confer and try to recommend something to the whole conference. On this committee was Phil Penna, as chairman of the conference; H. N. Taggart, C. H. Jenkins, Charles O'Neil, J. H. Pritchard and Tom Miller. This committee failed to agree and made only partial reports back to the conference. On Wednesday afternoon, after the operators in long separate sessions continued to make no progress, a joint committee of twelve was created by adding six miners to the original operators' six. The miners were: William Green, John Brophy, Frank Farrington, Arch Helm, Lee Hall and Frank Mooney.

This committee reported Thursday morning that it could agree upon nothing. Then, in the main conference, all sorts of plans were offered without success. A motion to merely set up a joint scale committee to try to negotiate the next wage agreement on a national basis got just six votes. A motion to restore the old four-state plan was beaten. A plan to divide the whole country into three districts, each to work out its own salvation independently, was squelched. The three districts would have been an eastern one composed of Ohio, Pennsylvania, West Virginia and Virginia, a central one with Illinois and Indiana as the principal members, and a western one to include everything west of Illinois.

John Lewis said he proposed in general terms a national scheme, a four-state scheme and a middle-ground which would have set up an enlarged "central competitive field" to act for the operators in wage negotiations. None of these aroused any enthusiasm.

Finally on Friday, the fourth day of the meeting, it appeared that some form of a competitive field was the only one on which any number of operators could unite. The central districts demanded that they at least have a voice in determining the policy which the proposed central group should follow in wage negotiations. Since this had possibilities, another operators' committee was named to work out something tangible. On this committee were Michael Gallagher, of Ohio; Rice Miller, of Illinois; Ira Clemens, of Kansas; Jesse Needham, representing Wyoming; Hugh Shields, of Indiana; John A. Donaldson, of western Pennsylvania, and B. M. Clark, of central Pennsylvania.

This group could produce nothing that would get an immediate majority, so, on motion of W. K. Kavanaugh, of Illinois, the conference adjourned to Dec. 6, with an operators' preliminary session beginning Dec. 4. The operators are supposed to return with new ideas for the grouping of districts and for the possible representation of all districts on some advisory council to function with but not to dominate a wage-making group resembling if not duplicating the Central Competitive Field.

The final statement to the public which John L. Lewis and Phil Penna issued said "some substantial progress had been made and there are reasonable grounds for belief that a definite program can be agreed upon."

The delegates to the joint conference, two operators and two miners from each union district, are as follows, with the two operators named first under each district number: District 2, Charles O'Neill, B. M. Clark, John Brophy, Richard Gilbert; District 5, John Donaldson, Jesse Sanford, P. T. Fagan, William Hargest; District 6, Michael Gallagher, J. H. Pritchard, Lee Hall, G. W. Savage; District 10, C. C. Anderson, J. H. Wallace, Martin T. Fitzsik, W. C. Thompson; District 11, Hugh Shields, M. L. Gould, John Hessler, William Mills; District 12, W. K. Kavanaugh, Rice Miller, Frank Farrington, Harry Fishwick; District 13, George Hogan, E. C. Smith, J. H. Morris, John Orr; District 14, W. L. A. Johnson, Ira Clemens, G. L. Peck, Van A. Bittner; District 17, [illegible] H. Jenkins, Joseph Pennycuick, W. M. Petry, Fred Mooney; District 21, J. R. Wilson (absent), W. M. Williams, J. L. Britton, Mike Brubaker; District 22, H. C. Marchant, Herbert Addison, Myrtle Cahill, James Morgan; District 23, C. W. Taylor, F. D. Rash, Lonnie Jackson, Wm. Adam; District 24, Warner Pippin, R. M. Randall, George B. Tookey, John Murray; District 25, F. W. Lakens, H. N. Taylor, Arch Helm, James Cooley; District 27, F. W. C. White, James Needham, Nathan Smethurst, Stephen Ely. Ex-officio operator members were Phil H. Penna, A. G. Edwards and J. M. Roan and miners were John L. Lewis, William Green and Philip Murray. Mr. Penna is permanent chairman of the conference, and Mr. Green and Mr. Edwards secretaries. Mr. Roan is sergeant at Arms.

Navy Department Opens Bids for Coal

Bids to supply coal needs of the Navy Department for the remainder of the fiscal year ended June 30, 1923, were opened on Nov. 14. The proposals were divided into two sections, one providing for delivery from November to the end of the period and the other for shipments during November and December only.

Among the larger bids were the following:

Twenty-eight thousand tons for delivery from November, 1922, to June 30, 1923, in 600-ton barges alongside coal plant at the Navy Yard, Brooklyn, N. Y.: Emmons Coal Mining Co., Philadelphia, $7.05; H. B. W. Haff, New York City, $8.68; Iron Trade Products Co., $6.75, alternate bids $7.13 and $6.74.

Forty-two thousand one hundred tons divided into (1A) 32,100 tons for delivery f.o.b. Philadelphia Navy Yard in hopper-bottom cars and (2A) 10,000 tons f.o.b. barges at Philadelphia coal piers, from November, 1922, to June 30, 1923; Emmons Coal Mining Co. (1A) $6.73; (2A) $6.48; Iron Trade Products Co., (1A) $6.55, (2A) $5.99, alternate bids $6.37; Morrisdale Coal Co., Philadelphia, Pa. (2A) $7.63; Quaker City Coal & Coke Co. (2A) $6.51.

Twenty-five thousand tons divided into (1B) 16,000 tons and (2B) 9,000 tons, for delivery as above in November and December, 1922: Iron Trade Products Co., (1B) $6.55, (2B) $5.99, alternate bids $6.37 and $5.88; Morrisdale Coal Co., (2B) $7.63; Quaker City Coal & Coke Co., (2B) $6.51; Dexter & Carpenter, (2B) $7.82.

Twenty-four thousand tons for delivery November, 1922, to June 30, 1923, f.o.b. dump-bottom cars on tracks in the Navy Yard, Washington: Davis Coal & Coke Co., $7.29; Iron Trade Products Co., $6.55; L. H. Snead & Co., Inc., Washington, $7.35; C. T. Blake Co., Cincinnati, $9.02.

Ten thousand five hundred tons for delivery January to June 30, 1923, f.o.b. hopper-bottom cars, White Plains, Md.: Davis Coal & Coke Co., $7.72; Emmons Coal Mining Co., $7.26; Fidelity Coal Mining Co., $1.30; Iron Trade Products Co., $7.12; Quaker City Coal & Coke Co., $7.49.

Twenty-eight thousand eight hundred tons for delivery November, 1922, to June 30, 1923, (1A) f.o.b. 300-ton barges alongside sea wall, and (2A) f.o.b. hopper-bottom cars, Naval Academy, Annapolis, Md.: Davis Coal & Coke Co., (1A) $7.44; (2A) $7.29; Iron Trade Products Co., (1A) $7.08; (2A) $6.93.

Ten thousand tons for delivery in November and December, 1922, as above: Davis Coal & Coke Co., (1A) $7.73; (2B) $7.58; Iron Trade Products Co., (1A) $7.08; (2A) $6.93.

The government states that awards will be made on the items for delivery either from November, 1922, to June 30, 1923, or for the short time period named—either November and December, or December—but not for both.

State Executives in South Discuss Means To Avert Coal Crisis

In connection with the fuel shortage the governors of Louisiana, Mississippi, Tennessee, Florida, Alabama and Georgia discussed means to remedy the coal crisis in these states at a conference Nov. 15 at Montgomery, Ala.

Federal action to prevent a coal famine in the South has been taken by the Fuel Administration in Washington, according to a telegram made public by the Atlanta (Ga.) Chamber of Commerce from the National Fuel Board. Immediate relief from the coal shortage in Georgia and other Southeastern states was the end sought by the Fuel Administration in issuing instructions Nov. 13 to railroads of the country to supply the Louisville & Nashville R.R. with 1,000 cars with which to handle coal shipments to this section within the following ten days.

Ask President Harding to Call Conference Of Somerset County Miners and Operators

Washington, D. C., Nov. 20.—A delegation of striking miners from Somerset County, Pennsylvania, headed by J. J. Kentner, of Lock Haven, who is serving them as general counsel, called at the White House today to request the President to call a conference between operators and miners in Somerset County. At the White House a printed statement was distributed setting forth some of the points of the miners' contention.

Anthracite Operators Submit Suggestions to Commission, Pledging Co-operation in Collection of Data

The general committee of anthracite operators submitted its suggestions to the President's coal commission on Nov. 18. The text of the document follows:

This is a preliminary reply to your communication of Oct. 26. We have under consideration detailed replies on a number of topics with respect to which the commission desires information. This information will have to be collected, compiled and verified, and it is hoped that instructions as to its character and manner of presentation will issue from the commission. Until the necessary facts have been collected, it is not practicable to make any useful reply to that part of your letter which seeks our "carefully formulated views as to what efficient policy, if any, could or should be adopted by the government relative to the coal industry, having proper regard to the interests of the mine workers, the mine operators and the public."

The Committee of Anthracite Operators will co-operate with the commission to the fullest extent of its ability in securing information that the commission may desire. We suggest that a questionnaire be prepared for submission to each operator. If the commission desires, our committee will collaborate with it in the preparation of this questionnaire. We believe that all information submitted should be verified by the commission of its agents whenever verification is deemed necessary.

With respect to paragraphs (e) and (f) of your letter, which refer to the "acknowledged demoralization" of the coal industry and measures for eliminating elements responsible for this condition, we understand from you that this is not intended to apply to the anthracite industry, where regular employment and a supply of domestic size coal commensurate with, but rarely exceeding, the public's requirements is, and for many years has been, the unvarying condition except when production is suspended by strikes.

Nineteen Topics Answered Seriatim

We now deal seriatim with the list of nineteen topics accompanying your letter:

I. Ownership and titles of the mines—Information on this subject can be obtained by questionnaire in the manner already suggested.

II. Prices of coal—We assume that the inquiry with respect to prices will comprehend ascertainment of the price at the mine and the price paid by the consumer. Mine prices of coal for any period the commission may care to investigate are obtainable from the operators, while the retail price of coal may be ascertained by inquiry in the various localities where it is consumed.

It may be properly mentioned in this connection that the producer of anthracite generally sells his product at the mine. One of the many sources of misunderstanding with respect to anthracite prices is the great difference between the mine price and the consumers' price, the latter including, in addition to the mine price, expense of transportation and the charges of middlemen and retail dealers, over which the operators have no control. Naturally the commission will investigate all of these items.

III. The organizations and persons connected with the coal industry—Data with respect to this subject may be obtained by the suggested questionnaire.

IV. Cost of production—This subject is, of course, one of the most difficult with which the commission will have to deal. Anthracite operations vary widely with respect to cost of production. They differ not only by districts but as to operations in the same district and even in immediately adjoining properties. A great many considerations, geographical, physical and economic, affect the cost of production. Generally speaking, the so-called company operations are upon owned lands, while many of the "individual" producers operate under short leases requiring more rapid amortization of the investment. Some leases require royalties in excess of $1 per ton on the "prepared" or domestic sizes and an extreme case exceeds $2 per ton at the present time. This subject may well receive the consideration of your commission.

Difference in the relative proportions of the "prepared" and "steam" sizes produced (the latter being sold below the cost of production), and the resulting realization on their sales, represent another important factor in the anthracite problem.

These factors are mentioned not as inclusive but as typical of the many considerations that must be taken into account in arriving at conclusions on the cost of production and the prices obtained for anthracite.

V. Profits realized by operators or owners of said mines during the last ten years—In this connection it is suggested that the work of the commission may be facilitated by reference to the information furnished by certain companies to the Federal Trade Commission covering the period from January, 1913 to Dec. 31, 1918, and by the analytical study of costs and profits made by the engineers of the United States Fuel Administration. Supplementary information to bring these data down to date can be obtained by the questionnaire method.

VI. Profits of other persons or corporations having to do with production, distribution or sale of coal. With respect to this subject the operators can be of little assistance to the commission, except in so far as coal-producing companies perform the functions of sale and distribution or have relations with other companies that perform these functions.

VII. Labor costs—All of the producers of anthracite are in a position to supply the commission with the labor costs of producing coal. These costs are kept in such manner as to be obtainable through the questionnaire.

VIII. Wages paid—The wage rates paid in the anthracite industry have for many years been fixed by agreement. The rates of pay, as well as the daily, monthly and yearly earnings of the miners and other mine workers in the anthracite field have been carefully tabulated by the operators and are matters of record, ascertainable by the commission. All supporting data collected by the anthracite companies is open to the commission. In addition, surveys of anthracite wages and earnings have been made by the United States Bureau of Labor Statistics and the National Industrial Conference Board. The results of these surveys are a matter of public record.

IX. Wage contracts—This committee will be pleased to supply your commission with printed copies of all agreements with the anthracite mine workers since 1902, as well as decisions of the Board of Conciliation interpreting these agreements.

X. Irregular production—There is little irregularity of production in the anthracite industry, except such irregularity as may be occasioned by holidays, legal and otherwise, strikes or accidental stoppages. The number of colliery starts is perhaps the best index to the regularity of anthracite production and the figures with regard to operation are available with respect to all companies.

XI and XII. Waste of coal, and suggestions as to the remedy for the same—This subject might be a large one, comprehend the whole problem of the production and utilization of coal and the production and transmission of power. We assume, however, that the commission is interested only in such waste of coal as may be under the control of the producers. We believe that the waste of coal in the mining of anthracite is negligible and not of sufficient moment to warrant investigation. Modern methods developed through engineering and technical skill in screening, reclamation and preparation have reduced waste to some extent that the term "waste" no longer applies, except in rare instances as are occasioned by burdensome legislation, notably the Kunkel and Fowler mine cave acts recently enacted by the Pennsylvania Legislature whereby otherwise available fuel has been rendered unavailable.

XIII. The conditions, generally under which coal is produced—Before making suggestions as to the method of investigating this topic, we should like to have the commission's interpretation of this heading.

XIV. Distribution—With respect to this question there is, we think, the opportunity for an investigation which will develop whether improvements and economies can be effected in the present methods of distribution. The distribution problem is not uniform in different localities and seasons, and the demand for the different sizes of coal varies. The investigation to be useful must be comprehensive.

Operators Promise to Submit Special Memorandum

XV. The causes which from time to time result in labor disputes thereby depriving interstate carriers of their fuel supply and otherwise interrupting the flow of interstate commerce.—At a later date the operators will submit to the commission a special memorandum upon this subject. While the immediate cause of general strikes is obviously a dispute between the employers and the employees as to rates of wages and conditions of employment, there are conditions especially affecting the anthracite industry and differentiating it from the bituminous industry, of which the commission should be fully advised.

In order that the labor problems which induce strikes may be considered on their respective merits, it is absolutely necessary that the anthracite industry be regarded as separate and autonomous, otherwise it will in the future, as it has in the past, become the victim of conditions and disputes with which it is in no way concerned.

XVI. All facts, circumstances, or conditions which would be deemed helpful in determining and establishing a wise and efficient policy by the government relative to said industry.—This subject has not, as yet, had the consideration which would warrant us in submitting our reply to you at this time.

XVII. Standardizing the mines upon the basis of their economic productive capacity and regarding the closing down of mines which by reason of their natural limitations or other conditions fall below the standard.—As pointed out above, there are considerable differences between the costs of production in various anthracite operations. It should be said in this connection, however, that there is rarely in any one year a surplus of domestic anthracite, and that it is necessary not only to retain but to encourage such as at present exist, to encourage production by those operations which are relatively high cost.

XVIII. Ascertaining and standardizing the cost of living for mine workers and the living conditions which must be supplied or afforded in order to surround the workers with reasonable comforts and standardizing wages so far as practicable on account of work a man shall perform for a reasonable unit of time, regarding the value and effect of such surroundings in respect of labor efficiency.—We are unconvinced of the wisdom or practicability of attempting to standardize the cost of living for individual workers or of standardizing the amount of work that will be performed upon such standard rather would economic forces adjust themselves to abilities and requirements. Human beings cannot be standardized.

Neither the wages of mine workers nor of any other group of workers can be considered independently of other wages. At the present time mine workers are receiving a scale of wages far above that paid in other industries, with the result that mine workers in these other industries are paying higher for the necessities of life. Continuance of such a condition cannot fail to have serious results upon the anthracite industry and therefore upon those employed in it.

XIX. Standardizing a basis of accuracy of the anthracite unit of production and distributing the cost accordingly between the different sizes of the commodity recognized in this connection that the standard cost of living in all centers should be the first and controlling item of expense.—[illegible] matters we suggest more definite information from the commission as to its wishes.

Additional suggestions.—We understand that the last question is the investigation of the anthracite industry should receive consideration of the commission between the companies and the mine workers. Quite recognizing and emphasizing that the conditions in the anthracite industry is the regular basis for bituminous industry and not the opposite, [illegible] The labor problem of the industry is one of the most important to be considered and especially as to causes of the serious loss and inconvenience to the public which have [illegible]

Improved Mine Rating and Car Distribution May Result from Assigned-Car Hearing

Supreme Court Hears Arguments Against Mine-Cave and Coal-Tax Laws

affected. John W. Davis, former Ambassador to Great Britain, declared the law to be "undisguised patent confiscation of property." H. J. Mahon, W. L. Pace, George R. Hull and Attorney General G. E. Alter, of Pennsylvania, defended the law.

The anthracite tax law was declared to be unconstitutional by H. S. Drinker, Jr. The Attorney Generals of New York, New Jersey, Massachusetts, Maine, New Hampshire, Vermont, Rhode Island, Connecticut and Delaware, in a brief which the court considered, contended that the law is an attempt to levy tribute upon the citizens of their states by taxing anthracite, 80 per cent of which is being shipped outside of the state. Lewis Marshall and J. Weston Allen opposed the law, which was supported by Attorney General Alter.

Ohio Dealers' Margins Revised

Following audits of various retail concerns in the larger centers of population of Ohio, C. J. Neal, State Fuel Administrator, has announced a revised list of dealers' margins covering many points. Under the new schedule, which followed protests made by retailers through the M.-O.-I. Coal Association, increases were made in quite a few instances. Likewise some reductions were made, especially in the rural sections. The total average change made by the new list is an increase of approximately 25c. per ton in cities and 8c. a ton in rural districts.

The new margins went into effect Nov. 18.

Reductions under this scale are: Mahoning County, 45c.; Erie, Summit, Medina, Stark and Summit Counties, 40c.; Wayne County, 35c.; Ashland, Clark and Trumbull Counties, 20c.; Columbiana, Darke, Fairfield, Greene, Knox, Lake, Lorain, Pike, Richland, Ross, Sandusky and Williams Counties, 15c.; Logan, Seneca and Madison Counties, 10c.; Fulton, Marion, Miami and Van Wert Counties, 5c.

Cities where increases have been allowed include: Steubenville, 72c.; Toledo, 60c.; Portsmouth, 53c.; Delaware, 50c.; Marietta, 48c.; Hamilton, Middletown, Springfield, Dayton and Canton, 40c.; Findlay, 35c.; Youngstown and Akron, 30c.; Lima, Columbus and Marion, 25c.; Bucyrus and Mansfield, 20c.; Sandusky, 10c.

Cleveland Retailers to Test Neal Ruling

Cleveland retailers have filed a suit in the Ohio Supreme Court asking a review of State Fuel Administrator Neal's ruling on retail margins as it affects that city. The suit was filed by twelve retailers who recently petitioned Administrator Neal for a revision of the $2.75 margin allowed in Cleveland and suburbs. In the petition it is asserted that Administrator Neal in refusing to increase the margin acted contrary to law and the evidence submitted in the hearing. It is claimed that the margin is unreasonable and unjust. The Supreme Court is asked to modify the ruling.

Retailers Invited to Present Data

The National Retail Coal Merchants' Association has been invited to meet with the U. S. Coal Commission on Saturday, Nov. 25. The commission is desirous of learning more regarding distribution and retailing of coal.

There will be a meeting of the members of the Governmental Relations and the Anthracite and Bituminous Trade Relations Committees of the association on Thursday and Friday, Nov. 23 and 24, at the Shoreham Hotel, Washington, D. C., when matters for presentation to the commission will be considered.

Railroads Volunteer to Co-operate

The railroads of the country tendered their complete cooperation to the U. S. Coal Commission in a letter sent Nov. 4 to John Hays Hammond, the chairman of the commission, by R. H. Aishton, president of the American Railway Association. The rail carriers, the letter points out, are the largest users of coal and therefore are vitally interested in the economic problems of the coal industry, not only from the standpoint of the consumer but also from that of the distributor.

Miners' Union Opposes Standardization of Mines, Living Costs and Amount of Work Performed

A committee composed of Ellis Searles, John Moore and Thomas Kennedy, representing the United Mine Workers of America, sent the following communication, under date of Nov. 18, to the United States Coal Commission:

In this communication the United Mine Workers of America desire to submit further suggestions in response to your letter to us dated Oct. 23. We have already, in previous communications, covered Topics 1 to 16, inclusive, except Topic No. 3, which is covered in this letter, together with Topics No. 17, 18 and 19.

17. *Standardizing the mines upon the basis of their economic productive capacity and regarding the closing down of mines which by reason of their natural limitations, or other conditions, fall below the standard.*

If the proper kind of competition among operators of coal mines can be established and maintained through the efforts of this commission no standardization will be necessary. Competition would itself eliminate the high-cost mines, because they would be unable to compete in price of their product with those mines in which the cost of producing coal is lower. We believe this idea, properly applied and fairly carried out, would not only reduce the number of mines and the number of miners in this country but it would also give the American public assurance of cheaper coal, because the coal would then be produced by those mines whose output is produced at a low cost per ton. In addition to keeping down the price of coal to the consumer, because it comes from low-cost mines, such competition would close many high-cost mines and thus conserve their resources for the future. We believe conservation of our coal resources is one of the most important propositions to which the American people should give their attention. There will come a time when coal will be less plentiful than it is now and the population of the United States will be much greater, thus calling for a heavier supply of fuel. Anything this commission can do toward conservation of coal for future generations should be done.

It would manifestly be unconstitutional for this government to attempt to eliminate any number of coal mines from operation by any sort of selective process. It could not assume to say to any mine owner: "You shall not be permitted to operate your property," and at the same time permit some other owner to continue operation of his mine. Nor could the government legally or constitutionally say to any miner: "You must quit mining coal and get another job," and then allow another miner to continue at mining coal. Therefore, we have no suggestions to offer in regard to the possibility of closing down any number of mines, unless this end can be brought about through the means of encouragement of open competition among coal producers.

In order that such competition might be encouraged and aided we suggest that every possible effort should be made to improve transportation facilities and the most efficient utilization of the transportation systems of the country. A way should be found to enable the railroads to equip themselves with a sufficient number of coal cars and locomotives with which to move the coal from mine to consumer. This commission will, in our opinion, accomplish great good if it can find a basis upon which to predicate a recommendation of a method by which this feature of the nation's transportation problem can be solved with equitable freight rates.

We do believe, however, and we recommend to this commission, that some means or method should be found to prevent the opening up of any new mines in the United States, at least for a considerable period of time. There are too many mines in this country now. If the mines now in operation or that are ready for operation were run to their capacity they would produce at least 40 per cent more coal than is required to meet all requirements of domestic and export trade. There is no need for any more new mines. Because a set of men own a railroad is no good reason why, under such conditions as exist today in the industry, they should be permitted to open up a lot of new mines merely to supply business and revenue to their railroad. Yet this is what happens continuously, and it accounts for much of the dislocation and confusion that exists in the coal business.

18. *Ascertaining and standardizing the cost of living for mine workers and the living conditions which must be supplied or afforded in order to surround the workmen with reasonable comforts and standardizing also as far as practicable the amount of work a man shall perform for a reasonable wage, recognizing the value and effect of such surroundings in respect of their efficiency.*

How this commission can hope to standardize the *cost* of living without at the same time standardizing the *level* of living of mine workers is beyond the comprehension of this committee. It seems to us that it would be impossible to standardize the cost of living unless each individual mine worker was required to accept and adopt a standard, identical level of living for himself and his family. Any attempt to establish such a standard as to fix a maximum or minimum limit to what the individual man might wish to adopt for himself as his level of living would not accord any system, either paternalistic or communistic that we know of. We are unable to offer any suggestion about standardizing the cost of living for mine workers." It would be easy enough for experts to prepare a budget showing the amount of food, clothing, etc., that is necessary to maintain a family of a given number of members on a level of decency and comfort but it would be impossible to standardize the cost of such budget. Flour that sells for $1 at one place sells for $1.25 at another place. Sugar sells for 6c a pound at one place and 7c a pound at another place. Gasoline sells at 20c a gallon in Indiana and 15c a gallon in the District of Columbia, though why we do not know. How could anyone hope to standardize the cost of living under such conditions?

We believe it is important, however, that this commission ascertain the cost of living for mine workers as suggested in Topic No. 18. We suggest that this could best be done by the employment of women investigators. Let these investigators go directly to the miner and his wife and learn from them the actual facts about their cost of living. They are the ones who spend the money and they are the ones who know what it costs them to live. We do not believe the commission should rely too heavily upon any showing that might be made by company stores as to the cost of living of mine workers. The best place to get information is the place where the information actually exists and in this instance the miner's home is the place. Your women investigators should delve into the mode of living as well as the cost of living. They could see for themselves the kind of food and the quantity of it that is supplied to the family. They could see the kind and quality of the clothing of the family and ascertain whether the quantity was ample. The miner's wife would not hesitate to talk on such matters with a woman, but she would, naturally, be reticent in her discussion of the subject with a male investigator. Let your woman investigator ascertain whether the miner's wife is contented or unhappy over her condition and why. Do her children attend school regularly or are they compelled to stay at home because of a lack of clothing, shoes or books? Are the children healthy or undernourished? If undernourished, what is the reason?

These are some of the human factors that enter into the subject and that are vitally affected by the cost of living and the ability of the miner to earn a sufficient income to meet this cost of living.

Hold It Impossible to Standardize Amount of Work

Standardizing the amount of work a man should perform.

We do not believe it is possible to standardize the amount of work a man can or should perform in the production of coal. Conditions vary in the various mines and workings. Seams of coal differ in thickness. It is easier to mine coal in some mines than in others. Some mines experience great difficulty with water, gas and other conditions. And so it goes, each mine being peculiar unto itself, as far as working conditions are concerned. Methods in use in one mine would be impossible in many other mines. Therefore, we do not see how the work could be standardized.

Again, there is no need of standardization, so far as the actual miner is concerned, nor for its effect upon the cost of production, because the miner is paid by the ton for the coal he produces and not by the day or hour. Therefore, the amount of his daily output is not important, in so far as it affects the cost per ton. It is also true that the labor performed by men who are paid by the day varies greatly in different mines and fields and what might be regarded as a standard of work in one place would be a flagrant misfit in another mine. However, the commission will find that the miners of this country are earnestly interested in everything that promises a better method for the performance of their work, and anything that will promote their safety and security.

19. *Standardizing a basis of arriving at the overhead cost of producing and distributing the coal, including delivery at the door of the consumer, recognizing in this computation that the standardized cost of living to the miners should be the first and irreducible item of expense.*

On the subject of how to arrive at the overhead cost of producing and distributing coal we have no suggestions to offer because this is a feature of the coal industry with which the miners have nothing to do.

3. *The organization and persons connected with the coal industry.*

In one of our previous communications we advised the commission that we desired to postpone consideration of Topic No. 3, "The organization and persons connected with the coal industry, until we could get a better understanding of what was meant to be covered by this topic. This subject appears to us to be a broad one, calling for much detailed information. It would contemplate, we believe, a study of all organizations and associations having any connection with the ownership, production, distribution and sale of coal. Under this heading the subject of absentee ownership of coal lands and coal mines could properly be investigated and the effect of such absentee ownership upon the industry and the public welfare could be determined. We believe the gold-bonded commercialism involved in absentee ownership is such a menace and evil in the coal industry that if this commission succeeds in and tells the public just how the selling price of coal is affected by it the commission will lay bare a factor that helps to keep the price of coal to the consumer at a higher figure than would be the case under any other circumstance. The public wishes to know why it is required to pay unreasonable prices for coal. We suggest that a study of absentee ownership will disclose one of the causes of this gouge.

The United Mine Workers of America is the trade union of the coal miners of this country. It has a membership in the bituminous and anthracite branches of the industry of more than half a million, scattered over the entire coal producing area of the country. We shall be pleased indeed to supply the commission with any and all information in regard to the United Mine Workers of America that the commission may wish for. The commission has no secrets and nothing to withhold from the commission. If you will indicate at any time the information you desire we assure you that it will be supplied promptly and in full.

At the same time, we have made the statement that it also requires all other organizations and associations in any way connected with the industry to open to the scrutiny of this commission. To this end all coal operators should be permitted to withhold nothing from the commission, nor should the commission permit any refusal on the part of any individual operator to supply full and complete information as to his business. It will be recalled that when the previous wholesale governmental activity prompted an investigation certain groups of the coal business certain coal-selling companies refused to be a party and obtained injunctions preventing the government from ascertaining the desired information. We do not know what these coal companies were so anxious to hide and keep from the government and the public, but apparently they feared to have the light of publicity turned on their affairs and business. We suggest that this commission be empowered to use the broadest and most drastic power on the part of any coal producer or the personal interests.

Coal Commission Begins Actual Collection of Data on Production Costs, Wages and Waste

By Paul Wooton
Washington Correspondent of *Coal Age*

While no comment has been forthcoming from any member of the U. S. Coal Commission, there is a feeling in official circles in Washington that the commission is entitled to more co-operation of an initiative type from both the bituminous operators and the United Mine Workers. There is a feeling that advantage was taken of Chairman Hammond's request for suggestions as to procedure, to get publicity, and that the reply was directed more to the newspapers than to the commission. It is the opinion of some that the bituminous operators and mine workers indulged in a lot of stock comment such as each side puts forward at every opportunity. Incidentally there is a feeling that the anthracite operators came close to complying with the spirit of the request. Their made reply to the questions that were asked, and a first-page position in the newspapers apparently was not their objective. Some read into each of the replies an intimation that the industry is all right except for the need to correct the other fellow.

It is apparent that the commission has not won the wholehearted support of any branch of the industry. Each side has been politely receptive and certainly has shown no antagonism. Some are inclined to attach some blame to the commission itself for lack of progress and for failure to obtain more active co-operation. It is pointed out that the commission has not made it plain to either side as to just what they would attempt to do. This failure to be more specific may have had a bearing on the disinclination of either side to commit itself. Some officials were hopeful that the industry itself would take the initiative with the commission simply satisfying itself as to the correctness of the information laid before it. The mine workers have not offered to open their records to the commission and it will not be surprising if many operators fail to furnish the cost data called for by the commission's questionnaire.

A detailed questionnaire as to costs of producing coal in 1921 and 1922 is being sent to all operators, large and small. Since a large number of mines were closed during six months of 1922, information is requested as to shutdown costs. So far as is known, no previous effort has been made to obtain this information. The work on these returns will be under the immediate direction of David Wing, who conducted similar studies for the Federal Trade Commission. Several of the members of the Trade Commission's staff who worked with Mr. Wing during that time and who are thoroughly familiar with the handling of production cost data have been transferred temporarily to the commission's staff.

Commissioners Neill and Alschuler are to be personally responsible for the results of the field investigation dealing with the cost of living and with living conditions. Each of these commissioners will devote a portion of his own time to work in the field. Mr. Neill already has made one field trip.

Wage statistics will be under the immediate charge of Prof. Joseph H. Willits, who will be assisted by Miss Anne Bezanson, who has had wide experience in such work.

C. E. Lesher, who has charge of the engineering phases of the fact-finding work, is getting together an advisory committee of engineers and operating men. He has arranged for co-operation with the U. S. Bureau of Mines.

C. A. Allen, who serves the Bureau of Mines and the State of Utah jointly as a mining engineer, will be transferred temporarily to the commission to gather data with regard to waste in the production of coal. In this work George S. Rice, chief mining engineer of the Bureau of Mines, will assist in an advisory capacity. This will involve an examination of the percentage of recovery and the present available resources in the more important fields. There will be an intensive study of the more highly developed areas with the idea of ascertaining reserves and the amount of waste.

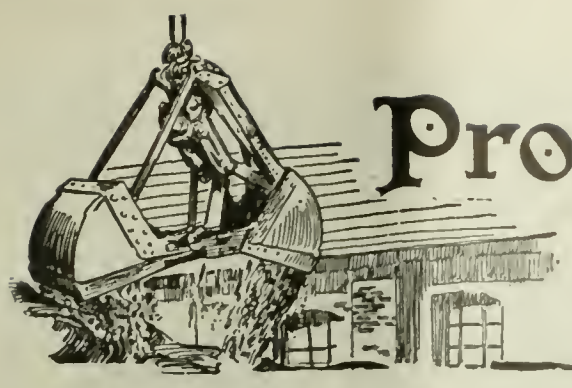
The study of retail costs and of the cost of distribution has not been launched as yet.

John D. Battle Appointed Traffic Manager Of National Coal Association

On Dec. 1 John D. Battle will become traffic manager of the National Coal Association, succeeding John Callahan, who has resigned to enter the coal-brokerage business in partnership with J. D. A. Morrow.

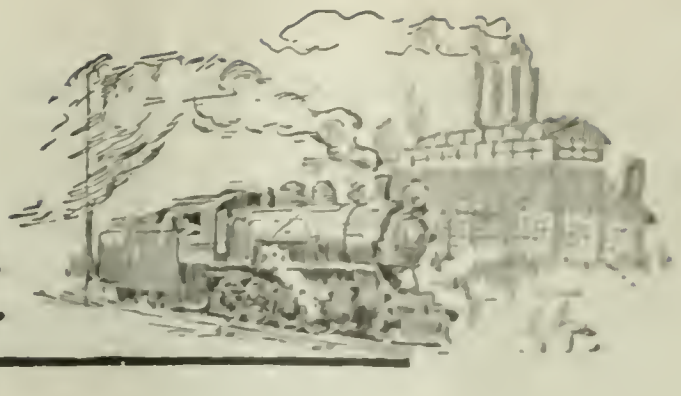
Mr. Battle has had long and varied experience in railroading. He was born in Greene County, Georgia, in 1887. He was successively telegraph operator, station agent and train dispatcher on the Georgia R.R. between 1904 and

Harris & Ewing



JOHN D. BATTLE

1911. From 1911 to 1918 he was with the Atlantic Coast Line and Charleston & Western Carolina joint terminals at Augusta, Ga.



He was connected with the car service division of the U. S. Railroad Administration at Washington from 1918 until the end of federal control of railways, handling the intensive loading and efficient use of freight cars. When the roads were returned to private ownership he became a traveling inspector for the American Railway Association. He was recalled to Washington in June, 1920, to direct the work of clearing up accumulations resulting from the switchmen's strike. Since Sept. 15, 1920, he has been assistant traffic manager of the National Coal Association.

Service Order No. 25 Modified

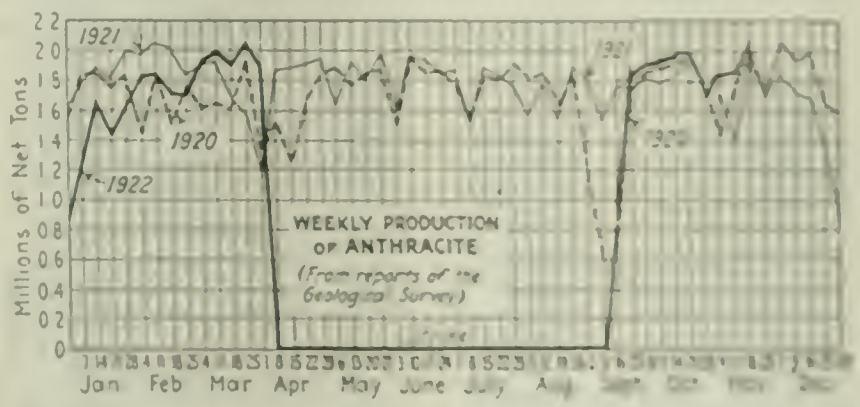
Service Order No. 25 has been suspended in part by the Interstate Commerce Commission in the territory south of the Potomac and Ohio rivers, with the exception of the lines of the Baltimore & Ohio in that territory. The amendment, effective on Nov. 18, removes the general priority in the use of open-top equipment for coal, but does not affect the original order for priority in the movement of coal. This action allows a greater use to be made of open-top cars for the transportation of road and building materials.

Production and the Market

Weekly Review

Spot buying is being done very quietly. The usual November snap is lacking, however, and a cold spell is urgently needed to bolster the trade. Domestic sales, while still strong, have felt the effect of the continued warm weather and prices have slackened a trifle. Day-to-day buying is still the only activity in the steam market, but that this is increasing in the face of steadily increasing production is shown by the recent trend in prices.

Coal Age Index of spot bituminous prices registered an increase this week for the first time since Sept. 25. The index number rose to 343 on Nov. 20, as compared with 340 this week before, 344 on Nov. 6 and 346 on Oct. 30. The average mine price corresponding to the index is $4.15.

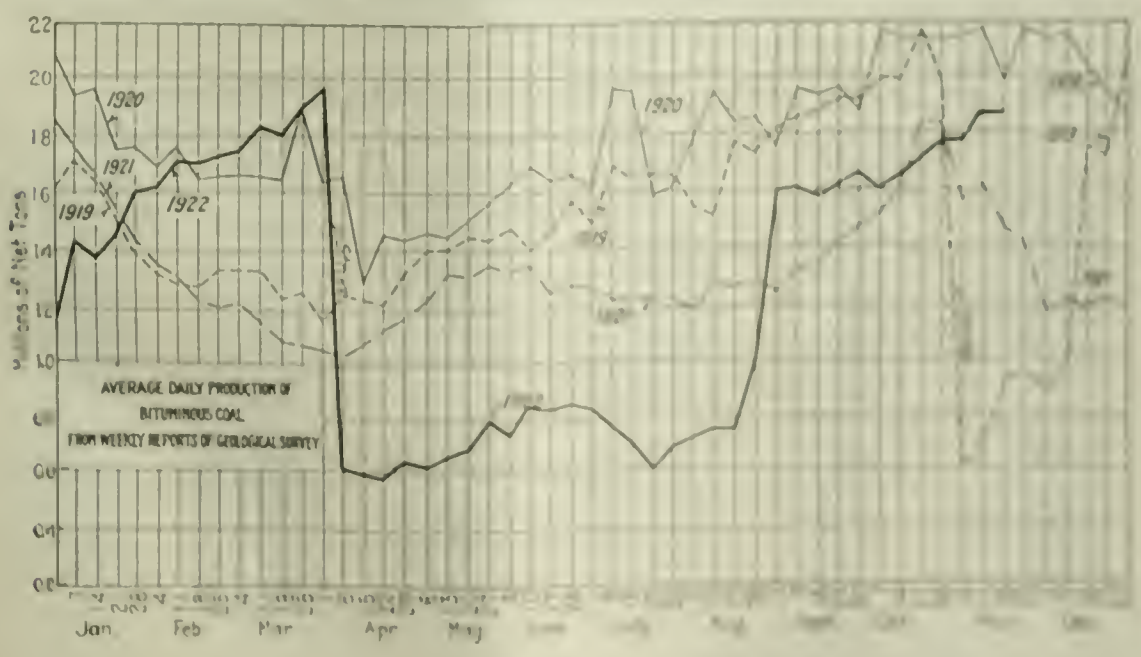


The increase resulted from unexpected strength at Hampton Roads and on good grades in central Pennsylvania. There is plenty of coal at the Roads but it is held by a large number of shippers and the market has been artificially strengthened by orders placed to piece out cargoes for tonnage waiting at the piers. High-grade fuels from central Pennsylvania are very scarce, and prices, which have held steadily for some time, are climbing slowly upward.

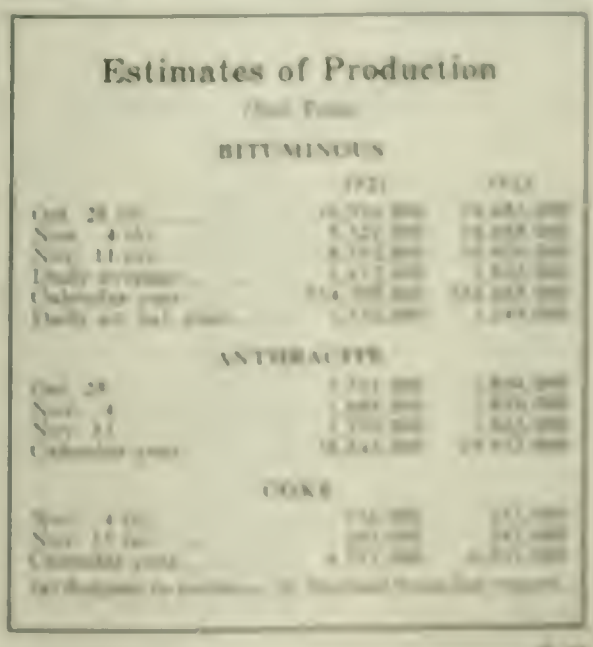
Only Low-Quality Coals Lack Ready Market

It is only the lower grade fuel that is feeling the want of a ready market. Consumers are willing to pay for quality and dispatch. Thus the market is divided between those who must push their coals, sometimes at concessions, and those whose main efforts are now directed toward the delivery rather than the sales factor.

Middle West markets are quietly absorbing more steam coal. This slight pickup, however, has been met so eagerly by producers that price betterment is almost imperceptible. Domestic sizes are somewhat softer as a result of warm weather. Retailers are unable to sell more than small lots and are slow to reorder. More and more mines throughout this and other sections are turning to domestic makes and this in turn is bound to affect the screening market. Railroads are buying steadily, convinced of the good values now offering and apparently realizing the transportation difficulties that are to come during wintry weather.



The Lake trade is drawing to a close. Dumpings are proceeding at the rate of 1,000,000 tons per week, but the movement will decline from now until the time when weather conditions stop cargo clearances. Many buyers

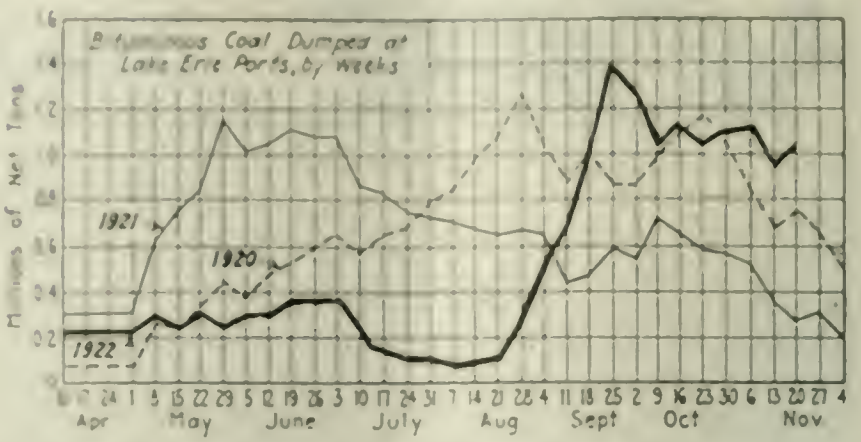


are waiting for the release of this tonnage, announcing their intention of taking on some stock when the offerings are increased by the diversion of Lake coal to commercial channels.

The Northwestern docks are feeling the keen competition of all-rail coals. Buying is increasing, but dock men are forced to shave their prices in the southern part of their territory. The Head-of-the-Lakes shippers feel these inroads keenly, as the curtailment of their territory increases their overhead and thus furthers the market advantage of the all-rail sellers.

Continued warm weather is providing a welcome delay in the matter of anthracite demand. Domestic sizes, of course, are in strong call, but there is no chance for

[illegible] will develop with cold weather. Substitute fuels are not being welcomed by householders, but as the anthracite shortage is a real one, mild weather will make their temporary use a necessity. Realizing this, various operators are producing domestic sizes for Eastern consumption and out of these emergency shipments is likely to arise a domestic bituminous market in what has always been an anthracite stronghold.



BITUMINOUS

"Preliminary estimates on production for the week ended Nov. 11, as revised by later reports reflecting the curtailed output because of election day and Armistice Day, put the total coal raised at 11,989,000 net tons," says the Geological Survey. "Early returns on car loadings at mines last week (Nov. 13-18) indicate 12,200,000 net tons, comprising 11,100,000 tons of soft coal and 1,100,000 tons of anthracite.

"Loadings of soft coal on Monday, Nov. 13, as reported by the railroads totaled 44,900 cars. On Tuesday loadings declined to 35,843 cars, and by Thursday had declined further to 32,576 cars."

All-rail shipments to New England were 3,529 during the week ended Nov. 11, as compared with 2,924 cars in the week preceding. Prices on Pennsylvania grades have increased, but not much spot coal is moving to this territory.

Hampton Roads dumpings for all accounts were 202,000 net tons during the week ended Nov. 16, as compared with 248,687 tons during the preceding week. Coal supplies at the piers are running evenly but are spread over a large

number of houses and a stronger market has resulted because of buying orders placed by a few shippers who must piece out cargoes for tonnage waiting.

Lake dumpings during the week ended Nov. 20 were 1,005,789 net tons—966,535 tons cargo and 39,254 tons ves-

Coal Age Index 343, Week of Nov. 20, 1922. Average spot price for same period, $4.15. This diagram shows the relative, not the actual prices on fourteen coals, representative of nearly 90 per cent of the bituminous output of the U. S. weighted in accordance first with respect to the proportions each of slack, prepared and run-of-mine normally shipped and second, with respect to the tonnage of each normally produced. The average thus obtained was compared with the average for the twelve months ended June, 1914, as 100, after the manner adopted in the report on "Prices of Coal and Coke, 1913-1918," published by the Geological Survey and the War Industries Board.

sel fuel—as compared with 987,430 tons in the preceding week. The movement for the season to date now stands at 17,571,005 tons, as compared with 22,625,575 tons during the corresponding period of last year. Market conditions in the Northwest are easy and all-rail coal is invading the southern part of the dock territory.

TIDEWATER SHIPMENTS FOR OCTOBER, 1922

(In Net Tons)

Destination	New York	Philadelphia	Baltimore	Hampton Roads	Charleston	Total
Coastwise to						
New England	120,000	45,000	45,000	654,000	4,000	868,000

Inside capes		143,000	111,000	90,000		324,000
Other tonnage	379,000		7,000	228,000	4,000	618,000
Total	668,000	231,000	186,000	1,128,000	17,000	2,230,000

ANTHRACITE

Production of anthracite during the week ended Nov. 11 is estimated at 1,863,000 net tons. Mines are producing to the limit of capacity in an endeavor to avert a serious shortage of domestic sizes, and in this they are aided by the unseasonably warm weather. Every effort is being made to push coal to the Lakes before the winter closes in. Dumpings spurted to 151,450 tons last week, as compared with 99,000 tons in the preceding week. The shipping season has been extended to Dec. 15, in an effort to make up as much of the deficiency as is possible.

Steam coals are still a drug on the market although

* Rail and river mines combined.
† Rail mines.

buckwheat is now in a fairly comfortable position because of better takings as a substitute for the larger sizes.

COKE

Production of beehive coke increased to 245,000 net tons during the week ended Nov. 11, as compared with 215,000 tons in the preceding week. The improvement was general in all the Eastern coke-producing districts. The Connellsville market is softer. Spot offerings have increased as the active furnaces are generally already covered for their requirements and pig iron is so sluggish that coke buyers urge the imperative need of lower prices.

Union Miners on Jury at Herrin Trial

Selection of a jury to try the first six prisoners held for murder in connection with the "Herrin riot" of June 22 goes slowly on. There are now seven men in the box. Some of them are union miners. Members of the union which is defending the prisoners have been accepted in the face of the state's best efforts to prevent it. Judge D. T. Hartwell, presiding, has ruled that mere membership does not disqualify a man. The recent special assessment, which operators are seeking now to fix the Herrin prosecution though they cannot prove riot, is being used by every union man who goes on the box. The entire force which the jurymen are being chosen to work as targets of miners—so largely in fact that it is hard to find one of its members.

Foreign Market And Export News

Heavy British Output Softens Market: Better Conditions in France

Record production has again broken the year's record. The output during the week ended Nov. 4 was 5,421,000 gross tons, according to a cable to *Coal Age*, as compared with the high mark of the previous week, 5,396,000 tons. The heavy output has congested the docks and railways, and demand has softened considerably.

The export trade of Wales has made great progress. For the four weeks ended Oct. 27, 3,170,800 tons were shipped from Welsh ports, and satisfaction is found in the fact that present exports are to normal directions, whereas the somewhat fictitious tonnage of late have been due to the stimulation which the trade received from the temporary business with the United States.

Forward business in northern England is rather restricted for the moment, owing to exchange difficulties, and fewer contract sales are in evidence. The Norwegian State Railways are in the market for 15,000 tons of best steam coal to be shipped between now and the end of December, the Malmo Gas Works are inquiring for 4,000 tons of superior Durham gas coal to be delivered over next year, and the Vagle Gas Works invite tenders for 2,500 tons of gas coals shipment during December. Several fairly substantial parcels of ordinary Durham bunker coals have been sold for delivery in monthly quantities over all next year at 21s. 6d. per ton, f.o.b., thus establishing a price basis for bunkering fuel which shipowners will note with interest.

Hampton Roads Supply Declines

Serious restrictive duty, due to the inability of shippers to get coal in sufficient quantities to supply the trade. The scarcity caused the market to strengthen, while demand increased slightly to indicate a trend of business toward better conditions.

Contract movement is showing a slight improvement, as is the bunker business, although export trading is indifferent, scattering cargoes being consigned to the West Indies in small quantities.

French Mine Activity Increases

French coal markets are now more active and the Center and the Center and Southern fields themselves are showing much improvement. The high value reached by the sterling exchange is, of course, proving very helpful to French collieries.

Mines of the Nord and Pas-de-Calais have order books well filled up. In domestic coals, most of the collieries cannot now accept immediate orders. The present scarcity of sized coals is a consequence of the reduction of output in Belgium and in the north of France.

Many consumers in the southeastern part of France, who usually order British coals, have now gone to the Loire field for supplies. Such is notably the case for several gas works on the Mediterranean coast. Important orders of coke from Switzerland and Italy are also sent to the same field.

Coal Paragraphs from Foreign Lands

GERMANY—Production in the Ruhr region during the week ended Nov. 4 was 1,751,000 metric tons, according to a cable to *Coal Age*. The preceding week's output was 2,005,000 tons. Production during October was 7,144,228 tons, exceeding the September production by 1,100,000 tons. The coal production of Upper Silesia in October as compared with September shows an increase of 5 per cent, while the October production in the Central German coal area was about the same as in September.

ITALY—The price of Cardiff steam fuel is unchanged at 40s. 3d. on the Genoa market, according to a cable to *Coal Age*.

BELGIUM—On the Belgian coal market the same activity continues and production is still insufficient to meet demands.

CZECHO-SLOVAKIA—In the second quarter of 1922 the output increased by 150,000 tons as compared with the first quarter. This represents an increase of 2.11 per cent in output, although the number of miners at work was less by 1.38 per cent. The new conditions of the collective agreement entered into force on Sept. 1.

PANAMA COAL PASSAGES DURING SEPTEMBER were 8,371 gross tons, as compared with 41,175 tons in August and 16,040 tons in September, 1921. Coal on hand Oct. 1 was 117,880 tons, 4,000 tons less than stocks on Sept. 1. During this month, 9,611 tons of storage coal were received.

Many Buyers Await End of Lake Shipping Season

Coal Will Be More Plentiful Hereabout Then, Is Belief—Some Producers, Finding Better Market With Hard Coal Scarce, Screen Lump Sizes to Fill Demand.

Lower-grade coals are freely offered, both on the spot and contract market. The better coals are firmly quoted, with little tonnage available. Deliveries are slow and uncertain and tonnage is being moved with little difficulty. The market, however, is still unsatisfactory for all except the consumer, who is able to obtain his currrent requirements—all that he is now buying—without causing any stiffening of the spot market.

Many buyers are awaiting the end of the Lake shipping season in the belief that more coal will then be offered in this section. There are scarcely any receipts of British coal. Certain producers report a better market because of the anthracite shortage and a number of them are now screening out the lump sizes to meet this demand.

BALTIMORE

The usual snap to a November market is totally lacking. The lack of demand is hard to explain even in the face of the fact that Baltimore was a bit more favored than some other localities to the distribution in October of more than 100,000 tons of English coals, and the movement during and just prior to that time of probably 100,000 or more tons which came by barge from Hampton Roads.

In relation to car shortage the weekly returns show that the run is not more than from 35 to 40 per cent on all roads. On one day the past week which can be taken about as an average, it was noted that the entire car supply on the B. & O. was 55 per cent. On the Connellsville division the supply was 27 per cent and on the Charleston division, 29 per cent. Several mines in the Somerset region last week reported on certain days that they had not received a single car.

PHILADELPHIA

If any one is satisfied in the soft coal trade it is evidently the consumer, who takes life easy in the confidence that he can get coal when he wants it, which is true to date. From the producing standpoint the old complaints of car shortage and unsatisfactory prices prevail. Possibly most shippers would admit that the prices are fair enough if they could produce coal anywhere near capacity. In the way of cars conditions are slightly better on the Pennsylvania, although there are some who complain bitterly of hardly any cars over a period of ten days.

There are occasionally reports of some producers willing to contract on coal of a Pool 9 grade at prices from $4@$4.25. Some arrangements on Pool 10 are also rumored, where considerable tonnage has been offered until April 1 at prices around $3@$3.25.

Market prices on high-grade coals are slightly firmer, while the low grades seem to have slipped a trifle. On the whole prdoucers are of the opinion, after following the market trend for the past week or so, that the lowest prices have been reached for the good coals.

There has been just the slightest tendency to betterment at Tidewater, at least there has been an increase in clearances, while bunkering holds its own.

CENTRAL PENNSYLVANIA

Production is gradually falling off, due in a large measure to a shortage of cars. The week ended Nov. 5 showed 18,594 cars. The week ended Nov. 12 fell to 17,287 and the week ended Nov. 19 will be considerably less. Unusual charges of discrimination are being made and there is much dissatisfaction.

The market is somewhat inactive. Unclassified coal is selling at $2.75@$3. Pools 15 and 18 are $3@$3.15; Pool 11, $3@$3.10; Pool 10, $3.75@$4; Pool 19, $4.50@$4.75; Pools 1 and 71, $5@$5.25.

There is some dissatisfaction in the district over the above ratings which may lead to new classifications. Some operators claim that grades of certain pools are better in some localities than others and that these ratings are unfair.

NEW YORK

There is a better feeling here. Demand is a trifle stiffer and quotations for the better grades show more strength. Prompt shipments are impossible. Car supply remains bad to which must be added poor motive power.

Producers have been rushing their coals to the West before the close of Lake navigation. When this takes place there promises to be a stronger demand along the seaboard by industrial users as well as by the railroads, who are not heavily stocked.

Buyers are cautious when making purchases and in many instances are buying from hand to mouth. However there has been a quiet accumulation in many quarters. Cold weather is the only solution of the situation, say many operators.

The number of cars at the local piers continues around 1,500, with comparatively little free coal being offered. This coal consists mostly of Pools 10 and 11.

Scarcely any foreign coal is coming here. Southern coals were quoted during the week on a basis of $7.40 f.o.b. Hampton Roads or about $8.40 New York. Some B. R. & P. coals were quoted around $3.65 f.o.b. mine during the week. Other prices are quoted in the Weekly Review.

FAIRMONT

Car shortage made itself felt to a very material extent during the week ended Nov. 11. Mines having Lake orders were given the preference in car supply. A disparity between Eastern and Western prices still exists, with mine run for Eastern delivery ranging $2.75@$3 and Western prices $3.75@$4.

UPPER POTOMAC

Loadings are still on a somewhat larger scale than the weekly average for 1921, with Upper Potomac mines getting out more tonnage than those in the Georges Creek and adjacent territory. Although the car shortage is affecting mines, producers are principally concerned now with market conditions, since there is not a ready sale in Eastern markets.

West

DENVER

In spite of an 18-in. blanket of snow and below zero weather, the *Denver Post* undersold retailers by lowering lignite in its "people's yards" 50c. to $6.35. The cold weather has livened up competition especially among lignite operators.

Reports reveal a movement among certain operators to bring suit against the railroads in Colorado before the I. C. C. for failure to deliver cars. One suits is said to have been filed by a Denver coal company. Members of the firm, however, deny the suit has been filed.

KANSAS CITY

The car shortage continues as brisket here. One operator reports less than 50 per cent production, with a strong demand for domestic sizes. Little hardship has resulted to the industrial users, although occasionally it has been necessary for them to accept other than their contract coal. Domestic deliveries are from two to four weeks behind and retailers are rationing their receipts.

Reports from Kansas and Missouri indicate that domestic buyers are still shying at the price, expecting a December break. While this simplifies the matter of supplying the present demand with a decreased car tonnage, it is thought to portend some difficulty later in the season unless the car situation improves. Kansas lump is $6, nut, $5.50 and screenings, $5.50. There is some off-grade production quoted at 50c.@$1 under these prices. Arkansas semi-anthracite lump quotations range $6@$8.

SALT LAKE CITY

There is a brisk demand now as a result of the increasing severity of the weather. Stocks are low with probably not more than 7,000 tons in the city's yards. The car situation shows no signs of improving.

President Ferguson of the dealers' association told the Coal Age correspondent he regarded the situation as serious. Many retailers here are coal and are trying to put their customers off until they can get shipments.

Anthracite

Unseasonable Weather Fends Off Clamorous Demand

Frigid Temperature Needed to Urge Buying of Substitutes—Some Bituminous Producers Screen Fuel in Anticipation—Push Movement to Lakes—Closing Date Deferred.

Mild weather remains the most favorable factor in the anthracite situation. Production is being pushed to capacity, but only the unseasonable temperatures prevailing have kept demand from becoming clamorous. Until consumers feel the urge of cold weather they will not buy substitutes to bridge the shortage, but, anticipating this, several producers of bituminous coal who ship to the East have made arrangements to screen their fuel. It is likely that a portion of the Eastern anthracite market, thus invaded, will become a permanent outlet for bituminous coal.

Every effort is being made to get coal to the Lakes before winter interferes. The closing date has been deferred to Dec. 15. During last week Buffalo dumped 451,450 tons, as compared with 99,000 tons in the previous week.

BALTIMORE

The hard coal situation continues to worry. In October the total shipment to Baltimore was 2,478 cars. To the middle of the month, according to estimates, the November receipts were around 600 cars. This leaves only 1,000 cars to be sent in the latter part of the month if the Baltimore allotment is to be kept up.

While there have been promises of increased shipments towards the end of December and early in December, it can be stated that the trade is far from optimistic along that line. The call from consumers who have no coal or whose small supplies are dwindling is becoming more active every day. There are a large number of consumers returning to their soft coal heaters against the time that they will get hard coal supplies, but real cold weather will probably drive them to cover.

NEW YORK

Conditions are more settled. Although the Metropolitan district would show little of the domestic trade there is no real shortage and everybody seems able to obtain a portion of their needs.

The closing of the Lake season will probably help the local situation. Dealers have many orders on hand and most are anticipating winter by ordering coals of their immediate comfort, even in fall purchases.

In Greater New York, especially the suburban districts, consumers have received 14,200 for Fort William, 8,500 for Port Arthur and 6,200 for Ashland, on Lake Superior.

Rates are strong at $1.25 to Racine and Kenosha, 60c. to Chicago, 50c. to Milwaukee, Green Bay, Waukegan and Port Arthur and 40c. to Duluth, Fort William and Ashland.

BOSTON

Mild weather continues the most favorable factor and it is felt that in the absence of bitter cold in the next three weeks and no unusual breaks in production we shall somehow pull through. New England is hoping to benefit materially when the last Lake shipments have been made, for certainly the heavy volume in that direction has curtailed the tonnage available for distribution here.

The retail trade shows no new developments. Stocks are of the hand-to-mouth character and deliveries are still restricted to one and two-ton lots. The Emergency Fuel Administrator of Massachusetts has raised a controversy over a recent price advance of one of the retail distributors here, claiming it to be unauthorized. Practically all the other retail dealers had already been obliged by mounting costs to increase prices. Similar, and in some cases, higher advances had been authorized in nearby cities and towns by the same functionary.

PHILADELPHIA

The expected shipments from the companies have not yet materialized, and the waiting is a severe strain both on the retailers and the consumers. From information that is given out it would appear that no real relief can be expected until Dec. 1 at the earliest.

Recently a shipper from the upper field flooded this market with cards to the effect that he had coal for sale. In reply to inquiries quotations were made as follows: Egg and stove, $12.65; nut, $10.75 and pea $8. One interested dealer went to the region and examined the nut coal and said that possibly 5 per cent of it might be coal. Another offering at $9 has been simply bank coal, with everything in it from stove to dirt. The number of dealers who are taking bituminous is increasing, but very slowly.

The steam sizes are little changed, with free offerings of all sizes at off prices, although the better buckwheats of the independents are still able to command full price. There is, however, considerable tonnage offering from that price down to $3.25. In rice coal the cut is even deeper and prices of $1.75@$2 are frequent, with barley freely offered at $1.25.

BUFFALO

The supply is so small that there are all sorts of complaint. Even the fuel administration is reminding the authorities in New York that the allotment is to be kept up, but there is no promise of more. All that is expected now is that the supply to the Lakes will be continued a week or two after the season closes.

The city is not buying much high-priced independent anthracite and some other sections have cut it off by fixing a maximum price. A prediction that coke for domestic purposes would not last past the middle of this month has not come true, for there appears to be as much as ever.

Lake loading suddenly increased to 141,450 net tons last week, of which 18,000 tons cleared for Milwaukee, 22,700 for Chicago, 9,500 for Racine, 7,000 for Waukegan, 7,000 for Kenosha and 4,500 for Green Bay, on Lake Michigan, 25,200 for Duluth and Superior,

South

VIRGINIA

With transportation conditions somewhat improved it was possible to speed up production to a slight extent, the aggregate output being in excess of 62 per cent. The improvement in transportation facilities was more marked on the N. & W., on the Interstate and on the Southern than on any other roads. The output is still somewhat short of market requirements notwithstanding a sluggish Tidewater demand.

BIRMINGHAM

Car shortage continues the principal disturbing factor, the railroads not being able to furnish on the whole over 50 per cent of the cars ordered. Contract mines are far behind on deliveries and furnace interests and coke manufacturers are not getting the desired amount of coal.

Inquiry for steam coal is light and spot business is taken care of without great difficulty. Consumers in general are holding off from the market as much as possible, buying only in quantities needed for current use.

The continued warm weather has somewhat softened the demand for domestic coal. However, the softness is only noticed in the lower grades. Indications point to the enforced use of mine run in considerable quantity, as the production of lump and other domestic sizes, in the absence of the usual stocks at this season, will not be sufficient to supply the winter's demand.

Prices are practically unchanged from a week ago. Production for the week of Nov. 4 was slightly better than the previous week, totaling 340,000 net tons, which was due to a temporary betterment in car supply.

Chicago and Midwest

Sluggishness Prevails in Most Midwestern Markets

Slight Steam Pick-up in Chicago Helps Flooded Market but Elsewhere There Is Nothing Encouraging—Domestic Prices Soften a Little.

Sluggish conditions rule most of the markets just now, thanks to the continued warmth. Kentucky producers are pushing hard to find markets for even their lump, and steam trade is not brisk there. Around St. Louis there are no bright spots. Almost every Illinois coal reaching that market is dragging in spite of the new effort of Distributor Spens and the United States Chamber of Commerce to encourage slow but steady stocking. In the Chicago market there is a trifling steam pick-up which has had practically no effect on a market already marked by a wide spread in quotations.

Railroads continue to buy slowly but steadily so that almost every line in this region has at least a normal volume on hand. They are getting a good deal of fuel at reasonable prices and are not so thoroughly convinced of a coming drop in price. Apparently the railroads have some knowledge of the possible car supply of the rest of the winter which other large consumers have not. There is no denying that many industrial buyers remain confident that they will be able to get plenty of coal even if real winter settles down for a long stay.

Shippers are sending a good deal of coal to distant markets where snappy sales effort has located a fair reception. This is helping materially to overcome the depression which slow local conditions spread.

LOUISVILLE

Due to comparatively light production in eastern Kentucky because of the usual poor car supply, and with much of the production under contract to Lake shippers, steel mills, railroads, etc., the amount of open market coal has been comparatively small. As a result, prices have been well maintained in spite of reductions in the competitive fields of West Virginia.

Eastern Kentucky mine run and screenings are selling at $3.75@$4 for non gas, and the gas or byproduct coals are $4@$4.25. Some 2-in. is reported at $6@$6.50, but block is selling at $6.50@$7, and quoted as high as $7.25. The margin between prepared and mine run is wide and has created a better demand for mine run, but with the Lake movement perhaps closing this week, some of the operators will be forced to screen more coal, and it is not believed that the margin can be maintained.

Retailers are buying as they need it, and not stocking. They anticipate a lower market on eastern Kentucky prepared by the latter part of November or early December, as car supply is showing improvement, and with Lake shipments cleaned up, the operators will be forced to hustle for business.

SOUTHERN ILLINOIS

A declining market on steam, no demand for domestic, with continued mild weather—that tells the story in this field. For the first time since the mines resumed in the Carterville field there are no-billed domestic sizes on track and here and there a few mines have found it necessary to make "repairs" and remain idle.

The association operators, however, are maintaining the price of $5.50 on lump, egg and nut. A few of the independents have cut to as low as $4.50, but it is not general. Screenings went down to $2, and then came back again about 25c. Car supply is not good. Railroad tonnage is good, everything considered. The bulk of the domestic tonnage is moving to the Northwest. Southern shipments are very poor.

Conditions are similar to this in the Duquoin and Jackson County field, except that on the Illinois Central working time is 2 days a week as a maximum. Mt. Olive is unusually burdened with steam sizes. Domestic is slow but a price of $4 for St. Louis shipments and $5 for country is being maintained. Steam nut is as low as $2.50, and screenings, $2.

In the Standard field conditions are extremely bad. Nearly all mines have no-bills and some of them are unable to work on this account. Lump coal is down to as low as $2.75 for 2-in. lump and $3.50 for 6-in., while screenings are showing a little strength at $1.25@$1.50.

ST. LOUIS

Warm weather and a jammed market has practically put the coal man out of business here, temporarily. All yards are loaded and the roads west of here are jammed up with consignment coal destined to Omaha, St. Joseph and Kansas City. The public is not buying. It is anticipating lower prices, or an unusually mild winter that may force lower prices.

Reports come in from the country districts that domestic and steam coal, which has been declining for several weeks, is dead because buyers are on the market for small quantities from day to day and are not stocking ahead.

Storage conditions locally are the same. With the exception of public utility plants there is very little storage. Gas plants in the Middle West have been unable to get any storage coal ahead, but are promised shipments during the latter part of the month.

Hard coal shipments have been curtailed and the public is resisting the prices. Very little local coke is offered but some is moving in from Alabama, and a little smokeless is coming from the East. The retail price has not been disturbed, but this may come soon if weather conditions do not change.

CHICAGO

An almost imperceptible steam pick-up is on now as was prophesied last week. It is not strong enough to have a general upward influence on the whole market as yet but it is viewed with pleasure by the selling organizations. Their very anxiety to meet the demand is retarding rising prices on small sizes and it is doubtful whether any increase at all has taken place.

The range is wide on steam coals so that a slow strengthening of prices is hard to detect. Jobbers have been unwilling all week to pay more than $2.25 for southern Illinois screenings, for the bulk of the business in that coal has been running $2.10@$2.50. Other Illinois screenings are selling down to $1.50.

While the call for domestic continues brisk there is more coal on the market that can be absorbed at top prices, and although choicest 6-in. southern Illinois lump continues to bring $5.50 to companies whose trade and service are well established, some shading has been made occasionally. Central Illinois with more production than it has known what to do with for weeks, has softened on 6-in. lump so that practically none goes above $4.75 and a good deal as low as $4. Slight softenings on Indiana domestic sizes a week or two ago have not been regained. Kentucky coals find an indifferent market here just now. The trade still yearns for a long cold snap.

WESTERN KENTUCKY

Lack of industrial demand and only a fair call for prepared sizes have resulted in the market working lower. Operators are now having trouble selling coal. Some are offering lump at $4 a ton rather freely, while others are holding at $4.25@$4.75, but not refusing much business at $4.25@$4.50. Mine run has worked off to $2.25@$2.50, and the low price here is probably being shaded somewhat. Screenings are quoted $1.25@$1.50 for pea and slack and $1.50@$1.75 for nut and slack.

Retailers have been buying a little more freely, but with warm weather they report slow sales and are refusing to stock, as they figure that even $4 a ton is out of line for lump coal and they do not care to have any heavy stocks on hand if the market shows further decline. The western Kentucky market as a whole is weak.

INDIANAPOLIS

Prices on Indiana coal seem a little weaker, due to the unseasonably warm weather. Some prepared grades are selling around $4, while screenings are slightly above $2.

Operators are at a loss to know just what the industrial users are doing for coal. There is little being purchased yet each day some reports of industrial economies that cuts the coal bill. The domestic situation shows no change. Retail buying is as slow as it could be. Prices on Virginia coal show little change but there are some grades of Indiana coal that are being offered by retailers at prices about the lowest that a week ago.

Eastern Inland

Spot Market Feels Lull As Lake Season Closes

Some Mines Having Ceased Shipments to Lower Ports, Buyers Expect Lower Prices—Operators Take Different View—No Marked Weakness in Steam Trade—Domestic Grades Moving Better.

The end of the Lake season is given as the reason for the lull in spot market activity. Some mines are already discontinuing shipments to the lower ports and within another week buyers profess to believe that this diverted tonnage will be available at lower prices. Operators, however, feel that this surplus will easily be absorbed with slight and only temporary price concessions.

Although the steam trade is dull, there is no marked weakness and the tonnage offering is easily sold. Domestic grades are moving better, not only because of milder weather but also due to the stimulating effect on Ohio production of the recent 50c. raise permitted by the Ohio Fuel Administrator.

CLEVELAND

Continued moderate weather and easing up of Lake shipments have combined to soften the industrial market. There is no market weakness, but the price for No. 8 lump is about 25c. less than it was two weeks ago. Mine run and screenings are holding their recent levels.

The supply of coal, however, has not increased greatly. This is largely due to the low car supply, which is reported as getting worse. Coal operators in the Ohio district have started an investigation into car supplies at Ohio mines. It is claimed in some quarters that this state is being discriminated against in favor of other states.

The Lake season is near its close and Ohio will release many cars for other uses. The warm weather has had a depressing effect upon the coal market and for the next month or so the state of the market will wholly depend upon weather conditions.

Purchases of fuel for household purposes are slightly less. With December and hard coal unavailable in adequate volume consumers have not yet had the urge of cold weather to place orders for less desirable grades.

DETROIT

Only a moderate degree of interest is assumed in offerings. Receipts fall short of the requirements of local consumers. This circumstance, however, seems to have little influence in stimulating a more active demand.

The close of Lake navigation, the jobbers believe, will not materially change the situation, except that for a few days cars may be more plentiful on the all-rail routes.

Coal now reaching Detroit is chiefly from Ohio mines. Hocking lump is $5.75, egg, $5.50, mine run, $3.75, nut, pea and slack, $4.25. Three-quarter Pittsburgh No. 8 is $4.75, mine run, $3.75@$4, slack, $3.50@$3.65. Fairmont lump is $4.75, mine run, $3.50@$3.75, slack, $3.50. Four-inch block from West Virginia or Kentucky holds around $6.50, mine run, $4@$4.50, slack, $4. Very little smokeless is available.

COLUMBUS

A decline in prices has taken place as the result of the near approach of the Lake closing. Mild weather has helped to cause the reaction although it would take quite a long cold spell to inject much strength in the trade. Retailers have larger stocks than formerly. There are hopes in the minds of consumers that prices will be lower and consequently they are only buying part of their winter fuel requirements.

Steam trade is rather quiet as most of the large users have accumulated considerable reserves. Buying for immediate needs is now the rule.

In the Hocking Valley, Crooksville and Pomeroy fields the car supply has been about 33 to 40 per cent. In eastern Ohio the output is close to 50 per cent because of a better car supply.

Orders have been given for no more Lake shipments from the Southern roads. Shipments from the Hocking Valley, T. & O. C. and Ohio lines will continue for some time, depending on weather conditions.

EASTERN OHIO

Due to lack of cars and restricted operations on Armistic Day, the output during the week ended Nov. 11 dropped below that of any week since mining was resumed in August. Production aggregated 272,000 tons or 44 per cent of capacity, registering a decrease of 24,000 tons under the preceding week.

Regardless of restricted output, steam demand has been tapering off and because reserve stocks are known to be too low for this time of the year some operators are apprehensive for the steam trade in view of approaching weather conditions which may seriously affect the already crippled condition of the railroads. However, it would seem that many steam users have deferred their storage programs until after the close of Lake navigation anticipating not only increase of considerable magnitude in available supplies of coal but a downward movement in prices.

Greatly increased activity has developed in the retail trade because of the milder weather now prevailing. It is expected that the 50c. additional granted by the Ohio Fuel Administrator, effective Nov. 15, on prepared sizes above 34-in. produced in Ohio will stimulate production.

Spot prices in the main adhere to those set by the State Administration. Retailers say that smokeless lump from eastern Kentucky and West Virginia is becoming more plentiful but the price range is $6@$8.

Cleveland received during the week ended Nov. 11 the largest volume of bituminous coal on record. The total arrivals were 2,430 cars, divided: 1,775 to industries and 655 cars to retail yards. Average weekly receipts during the last quarter of this year now average a little less than 2,000 cars per week.

PITTSBURGH

While there are wide variations in car supplies from day to day, the average remains fairly steady at something like 40 per cent of mine ratings. Distribution is much the same as formerly, to the Lake trade, industrial consumers and domestic consumers. In general the coal is moving on contract, usually with a weekly or monthly adjustment of price, no large tonnages of spot or prompt coal being sold as a rule.

The iron and steel industry continues to show very heavy production. Since Oct. 1 steel production has been at a rate about 15 per cent greater than the average rate April 1 to Oct. 1, and it is seriously questioned whether steel consumption can support such a rate of production throughout the winter.

Current market quotations are as a week ago. The undertone of the market is plainly softer and next transactions of any consequence are expected to be at say 25c. lower, for spot and prompt. For shipment over the month of December, however, prices are expected to be firm as weather conditions are likely to make fresh transportation trouble.

BUFFALO

Demand continues what the shippers call light, yet it may be as heavy as the consumption, and if it is, the trade will have to stand it. As a rule the complaint of car shortage is as great as ever, but there is less looking for a collapse in consequence of lack of transportation.

Much complaint is heard from operators on account of the great surplus of miners in all regions. This makes it necessary to suspend work a good part of the time and if cars were not so scarce the market would be broken down. The high wages enables the men to get along without working more than half the time. It is a state of affairs that nobody seems able to change for the better. So long as it lasts the labor situation in the mines will be bad.

Shippers are putting out their coal more on its merits than they used to. They can find customers who will pay an extra price for extra quality. This is a good thing to do, for it increases efficiency and confidence in the trade. All the way up to a dollar a ton extra can be had in that way.

Prices are fairly firm at $5@$5.25 for gas lump, $4.75@$5 for steam lump, $3.25@$3.50 for mine run and $3@$3.25 for slack, Allegheny Valley prices being somewhat lower than these figures, on account of quality and lower freight rates.

NORTHERN PANHANDLE

Operations were more curtailed than during the preceding week owing to difficulty in securing cars. The West afforded the best market owing to the fact that higher prices were being paid. Mine run commanded $3.25@$4, with prepared bringing $4.50@$5. Slack ranged $2.75@$3.50.

Northwest

Hard Coal Short but No Bituminous Famine Ahead

Allotment of 60 Per Cent of Normal on Anthracite Not Expected Now—Substitutes Grow Commoner — Rail Trade Cuts Docks' Soft Coal Business.

Nobody expects the full 60 per cent allotment of anthracite to reach these states now. The shipments have been too light and rail coal from Pennsylvania probably will not come through as was expected. Even the extension of the navigation season to Dec. 15 is hardly enough to let sufficient hard coal in. Many substitutes are getting a trial. The anthracite price has ascended about $1 in most Northwest markets.

The territory is well supplied with bituminous, however. Rail shippers have been making hay while the sun shone through the early fall months. The result is rail competition is now cutting more heavily into the docks than it ever did before. An organization to promote this trade is working briskly at Minneapolis and St. Paul, announcing that it has designs on a good deal more business than it has landed yet.

MILWAUKEE

The market is featureless at present, and may continue quiet until winter weather stirs up consumers. Dealers are only reasonably busy, and the entire market lacks pep. Prices continue undisturbed. If an advance comes, it will not be until navigation closes, and future supplies depend upon rail service. There can seemingly be no pretext for advancing soft coal, but the anthracite situation is unquestionably bad.

Nine cargoes of hard coal were unloaded during the first half of November, the aggregate being 76,839 tons. This makes the cargo receipts of hard coal since the opening of navigation, 218,953 tons. Soft-coal arrivals during the same period aggregated 2,131,211 tons. Last year the receipts to date totaled 923,881 tons of anthracite and 2,502,099 tons of soft coal.

DULUTH

If any one feature of the market stands out at present, it is the anxiety over the hard-coal situation. At present it does not seem that more than 600,000 tons can possibly be delivered before the close of navigation. This is about 40 per cent of the normal supply. The lower part of the state may get relief by all-rail from mines. Pocahontas briquets are coming into favor as a hard-coal substitute.

No anxiety is felt about soft coal. There has been a falling off in demand from mining companies on the Iron Ranges. One company has relinquished an option on 10,000 tons of steam coal. This lack of demand is thought to be because of the results of the recent elections here. Minnesota is leaning toward the farmer-labor party candidates—in fact has sent a man of that party to the United States Senate—and these are known to be in favor of additional taxes on iron mining.

Last week saw receipts of but forty-one cargoes, of which six were anthracite, as against forty-nine the week before. Only twenty-one cargoes are reported as having loaded out of lower ports for here. The market on hard coal is, of course, strong, though there will be no general advance. The differential of $1.05 a ton, mentioned two weeks ago has again appeared. This is coal from non-union mines. Railroads are out of the market, evidently waiting for lower prices.

MINNEAPOLIS

The fuel directors have announced that the danger of a serious shortage in the Northwest is now remote except in hard coal. On soft coal, it has been entirely a matter of transportation for a number of weeks. The supply will hardly be enough for the entire winter on the basis of the stocks so far sent to the Northwest. But between the stores on the docks and the tonnage received all-rail, plus the tonnage which may reasonably be expected to come during the remainder of the winter, all rail, the Northwest will doubtless get through without difficulty.

Anthracite has come very slowly so far. The tonnage has hardly amounted to 20 per cent, well into November. As the district was allotted 60 per cent of a normal supply, arrangements have been made to extend the period of Lake navigation beyond the usual closing date to Dec. 15, in the hope of making up the deficiency.

The rail trade has about flooded the Twin Cities with soft coal and has put up a competition which has forced down dock prices constantly. Rail coal and dock coal divide the business in the Twin Cities and even north of those cities, while south of there rail coal is taking a bigger portion of the business than ever.

All this means a great deal to the dock business, which has hard work to make a showing with the costs running high for maintenance of docks, freights by rail and water, handling charges and the like.

New England

Smokeless Supply Runs Low, But Demand Is Almost Nil

Car Supply Erratic—Small Users and Retailers Tag Along, Relying on Dull Market to Supply Short-Notice Needs —Broad Market Still Far Off.

The situation of smokeless grades has changed materially at the mines and at Hampton Roads. Instead of accumulations at the terminals there is now in most cases an actual shortage, and more than a few bottoms have been obliged to wait from three days to a week for cargo. Car supply is erratic, due partly to heavy shipments West earlier in the month and to failure to return cars on the part of Western roads.

There is almost an entire absence of demand here. At the same time there are smaller users together with retail dealers who are running along on light stocks, relying upon a rather lifeless market to furnish what coal they may need on short notice. If Pocahontas and New River advance in delivered cost there is still the central Pennsylvania area to draw from, and it may be that seaboard buyers will not overstay. The corporations are all loaded up with British coal, supplemented by current deliveries on contract via Hampton Roads, and for that reason it is difficult to figure out any broad market for a long time to come.

While Southern coals have been advanced moderately on cars Boston and Providence for inland delivery, $8.50 @$8.75 being the current level, most of the Pennsylvania grades offering here have remained stationary as to price. A few of the more desirable coals were advanced a fortnight ago, but the producers have now found that cars are catching up with orders in hand and they are again combing over the market for consignments.

Coastwise freights from Hampton Roads are still on a minimum basis and prices on Pocahontas and New River have not yet advanced sufficiently to furnish an opening for Pennsylvania coals by water except at distant water points. A few small cars have begun buying Cambria coals by this route on the assumption that prices are about on the bottom.

Receipts both by water and all rail show a falling off, but this was only to be expected. Everything considered the volume has been reasonably strong since early July, and in view of relatively light consumption by the railroads and by New England industries it was almost certain there would be a diminished movement in November.

The long-fought battle on the wharfage question, which had been effective from Feb. 15 was brought to an end the past week. The operators have accepted the original terms offered by the railroads, and now most of the mines will be in full operation, as trade conditions will permit.

Cincinnati Gateway

Cold Weather Hoped For To Offset Lake Closing

Price Drop Expected Unless Temperature Falls or Transportation Fails—Prices Propped Up by Eleventh-Hour Lake Rush—Domestic Demand Exceeds Supply

Weather conditions are being anxiously scanned these days, it being felt that colder weather or crippling of transportation is the only element that can stave off a drop in prices with the close of the Lakes. The C. & O. officially brought the season to a close on Nov. 18 and the N. & W. ordered all shipments over the Portsmouth scales cleared by Nov. 22. There was an eleventh-hour rush to fill out certain cargoes which helped to bolster prices for a few days, but softness again set in and a drop of 50c. followed.

Domestic prices are holding their own with the demand still overtopping the supply. The slack prices will get the severe cut in readjustments, it is believed, indications already pointing in that direction. The movement of empty cars is sluggish. Transportation is now the key of the situation.

CINCINNATI

Though more and more mines are turning toward the make of prepared coal there is a sufficient amount of takers to hold this part of the market firm. Lump shipments from Hazard, Harlan and Logan begin to show heavier and to this shortly will go a large amount of coal that has been moving to Pool 4.

Steam requirements are not being forced on the market and the buyers of byproduct are lying back, evidently waiting to see the next developments.

The smokeless business goes along on an even keel and the representatives here do not look for much change in the tariff of the season. Top prices are still possible on the steam sizes and some byproduct plants are still paying a premium on the tonnages.

There has been no change in the coal situation. Generally speaking, the retail prices are 50@75c. below the limit set by the Ohio fuel authorities.

HIGH-VOLATILE FIELDS

Kanawha

The output of the region is not more than half the week's average of last year. Although the demand has been of a desultory nature, various conditions have not affected operations, owing to the fact that the output is not sufficient to fill contract orders. There is hardly an item of Eastern coastal for steam grades, the prices are so low in the East that very little coal is moving in that direction. The spot price on mine run for Western delivery ranges $3.75@$4 as against $2.75@$3 in Eastern markets.

Logan and Thacker

Logan mines, with somewhat better transportation facilities, have been able to speed up production to some extent. Much of the additional output has been absorbed by the Lake trade. Producers are behind with orders for regular customers and are still working to a great extent on contracts. Little of the tonnage is finding its way to Eastern markets, a much better price prevailing in the West.

There has been little fluctuation in the output of the Williamson field in recent weeks. It still remains at about 50 per cent of potential capacity. Owing to this limited production, it is not possible to more than fill contract orders. The bulk of the output is moving westward.

Northeastern Kentucky

Notwithstanding a small increase in the output the market is keeping pace with the larger production. The current demand is more than sufficient to absorb any surplus spot coal and a few large contracts are being placed at prices somewhat better than the current market prices. It is possible as a rule to secure about $1 for mine run, with prepared grades ranging $6@$7.

LOW-VOLATILE FIELDS

New River and the Gulf

Better facilities for Western movement are tending to reduce the amount of New River tonnage available at Tidewater but without enhancing the price. Producers are greatly handicapped by a poor car supply, few mines being able to secure more than 26 per cent of allotment and hence not loading more than 115,000 tons per week. Contract orders are absorbing nearly the entire output, so that after all there is little spot coal to be had. The scarcity in the West is reflected in a price of $5.50@$6.50, but at Tidewater the range is $1@$1.25.

Coal is somewhat more plentiful at Sewell's Point than at other Tidewater piers. Gulf mines are handicapped to a great extent by limited transportation facilities and principally by lack of adequate motive power. Although these facilities are inadequate they are being slowly improved by the Virginian.

Pocahontas and Tug River

Any advantage to the Pocahontas field as a result of the lifting of Western embargoes has been more than offset by a curtailment of transportation facilities in other directions. It is not possible to send much more coal to the West than it was while embargoes were in effect. The shortage of empties is also reducing the movement to Tidewater. The trouble seems to be in getting cars back on the home line. It is out of the question to handle many spot orders and that is contributing to a scarcity of Pocahontas coal in the West, as a result of which prices are strong.

Shipments from the Tug River region are being made to a great extent to Western points. The output is so limited, however, that mine owners have all they can do to keep up with contract orders so that after all little spot coal is being marketed. The average price on mine run from this region is $5.50@$6.50.

Coke

CONNELLSVILLE

The coke market has declined again, losing 25c. on furnace and 50c. on foundry, spot and prompt being now quotable at $6.75@$7.25 and $7.50@$8.50 respectively.

The market seems full of coke now, as production has continued to increase and consumption does not increase materially. The market has poor absorbing power since nearly all the furnaces dependent on Connellsville merchant coke have contracted to the end of the year and thus there is little occasion for furnaces to buy at this time.

It develops that when the market broke, about a month ago, most of the furnaces concluded they would be taking a narrower chance by buying than by not buying. Accordingly, there was much contracting to the end of the year at $8@$8.50. These transactions the furnaces now regret, as the further declines in the coke market do not help them while they have an adverse sentimental effect on pig-iron prices, which are sagging almost constantly.

The *Courier* reports production during the week ended Nov. 11 at 115,600 tons by the furnace ovens, and 61,280 tons by the merchant ovens, a total of 176,880 tons, an increase of 12,560 tons.

UNIONTOWN

The three coke plants of the Oliver & Snyder Steel Co., closed since the strike last April, resumed operations last week, prior notice having been served upon employees to return to work or vacate company houses. These plants are the last of the larger independent plants to recover from the coal strike. While technically the men are still "out" in the Connellsville region, operators are producing all the tonnage needed.

Railroads and the Lakes are taking practically all the coal tonnage from the Connellsville region. The Eastern market is described as "quiet." There continues to be no revision in coal prices here, steam coal being quoted at $3 and byproduct, $3@$3.50.

The coke market has not strengthened to any extent and the price resistance is met by operators with a claim of increased cost of production because of the strike. Furnace coke is quoted $7@$7.50 with foundry $8.50@$9.

BUFFALO

Furnace demand is still light, but domestic movement is so large that certain producers have put up their prices $2 or so. Jobbers quote foundry at $8.50@$9, furnace at $7.50@$8, and off-grades and stock at $6@$6.50, adding $3.28 for freight. Local byproduct furnaces demand $12@$14 for domestic sizes with various minor freight charges.

News Items From Field and Trade

ALABAMA

It is reported that **Watt Brown**, of Ragland, will undertake the development of coal properties in that county, where he is interested in a large acreage of land. It is also understood that **Joseph G. Rowell**, who is operating mines at Inland, in St. Clair County, will electrify his plant and install a coal washer.

The Beechy Hollow Coal Co. has been organized at Dora by Olin Goodwin, C. I. Jones, of Dora, and T. E. Dunham, Birmingham, and has taken over the old operations of the **Burnwell Coal Mining Co.** at Burnwell, near Dora. The new properties recently developed by the Burnwell company in Walker County were not included in the transaction.

James Bonnyman, who has been a prominent coal operator in the Birmingham district for a number of years, being one of the officials and owners of the **Brookside-Pratt Mining Co.** and previously connected with other mining developments, will move to Cincinnati, where he will reside in the future.

At a meeting of the board of directors of the **Alabama Mining Institute** recently held, **Frank Nelson, Jr.**, was elected president for the ensuing year, succeeding **Frank Crockard**, of the Woodward Iron Company. All the other old officials will hold over until their successors are elected later on.

At the election of Nov. 7 an amendment to the state constitution authorizing the state to lend its **credit to the exent of $10,000,000 to the harbor commission** for improvement and enlargement of harbor and port facilities at Mobile, was approved by a large majority. Considerable Alabama coal passes through this port yearly.

COLORADO

With the opening of the **Nushaft mine** of the **Colorado Coal & Mining Co.** at Coal Creek, all of the mines of this company in the Fremont County field are in operation. This mine had been idle for several months.

Settlement of the bituminous coal strike **in the San Juan valley** has at last been made. The operators have agreed to pay the 1921 union scale to miners, which calls for $1.14 per ton on veins in the neighborhood of 6 ft. The working of the smaller sized veins, which calls for a higher rate of pay, has been stopped.

CONNECTICUT

The Molstein Coal Co., of New Haven, has recently filed papers of incorporation to engage in the coal and fuel business, conducting yards at New Haven. The firm will have a capital stock of $100,000, and will commence business with $75,000.

The City Coal Co., Hartford, has applied to the War Department, at Providence, for permission to construct a new front on the dock and wharf in the Connecticut River. This would give the company much more facilities to handle incoming coal.

Anthracite to the amount of **172,870 gross tons entered Connecticut during October. This was 9,870 more gross tons than was** to be allotted to the state, the allotment being 163,000 tons, or 60 per cent of the normal monthly supply. All-rail shipments amounted to 123,533 tons and Tidewater shipments to 49,340 tons, the latter exclusive of Tidewater coal mined by the Philadelphia & Reading Co., which is sending most of its coal west, New England receiving meager shipments.

ILLINOIS

Harry M. Goodnow, for several years chief engineer of the Equitable Coal & Coke Co., with mines at Johnston City and Du Quoin, has been made superintendent of one of the mines at Johnston City. **Arthur M. Lee**, formerly assistant to the chief engineer has been appointed to fill the vacancy made by Mr. Goodnow's promotion.

The Bradenbery Coal Co. of Davenport, Iowa, has purchased one of the largest drifts at Breeds, Ill., and is enlarging and improving it and expect soon to be mining coal in large quantities.

Work is now well under way on the sinking of the large mine two miles east of Percy, by the **Willis Coal & Mining Co.** The Jones-Avis Sinking Co., of West Frankfort, is doing the work. The shaft is to be 18 by 11 ft. in the clear and will be 130 ft. deep. The mine will be equipped with steam hoists and electrical haulage and hauling machinery underground. It will be served by the Wabash, Chester & Western R.R., which is already working on a branch from its main line to the mine site. The mine, under lease by the **Southern Gem Coal Corporation**, is expected to be in operation in from eighteen to twenty months, and may produce 6,000 tons a day.

Indictments have been returned by the federal grand jury, charging **an intricate system of fraud in coal shipments**, by which railroads were mulcted of as much as $300 a day for months. The indictments were against **James C. Michaels**, president of the Chest Creek Coal Co., and **Daniel J. Kinrally**, an agent of the company. State indictments against the two men were returned last April. Federal investigators report that the fraud was worked by reporting carloads of coal received in bad condition, then, before the road checked up the report, $400 or $500 worth of coal would be removed and reported lost.

The Hoy Coal Co., Springfield, has just been incorporated. The incorporators are George W. Schwaner, Carl Hoy and W. R. Whitney.

Edward Gartner, of Pittsburgh, and **George B. Worden**, of Edwardsville, are preparing to sink a coal mine north of Edwardsville. Several prospect holes have been located and drilling has been done by the Pittsburgh Drilling Co. Options have been taken on about 10,500 acres of land from more than 90 farmers. Pittsburgh capital is said to be interested in the new mine.

The Standard Turbine Corporation, of Wellsville, N. Y., has appointed **E. E. Maher**, district sales manager in Chicago, with offices in the Insurance Exchange Bldg. The Chicago office will handle business for the greater part of Indiana, Illinois and Iowa.

IOWA

The Norwood-White Coal Co. of Des Moines has recently opened a large coal mine near Herrold. The company has inspected a wide coal field and it is probable that several other mines in that vicinity will be opened. The mine is to be equipped with electrical machinery.

KANSAS

Theodore Langenbergh, engineer for the Phoenix Utilities Co., has opened headquarters in Oswego, and has started on a survey of the company's options on coal lands near that city, preparatory to drilling. The primary object of the company is to exploit the field for the use of its big power plant, which is under construction.

KENTUCKY

A report from Whitesburg is to the effect that the **Isaac Lewis Coal Co.** has sold several mines to the **White Elkhorn Coal Co.**, of Detroit, which plans for enlargement of capacity.

Approximately $80,000 was the amount of the verdict awarded **M. M. Tyree** of Charleston, W. Va., against the **Kentenia Coal Corporation**, of Pineville, in a suit in the United States District Court at Covington. The judge instructed the jury to find for the plaintiff. The defendant company sought to secure a continuance but the motion was overruled. Suit instituted by Tyree was to recover the sum of $[illegible] with interest, the plaintiff claiming that [illegible] was due him as commission [illegible] as profits as a stockholder during the time he was managing agent and sales agent for two years. Tyree testified that as a stockholder he attended a stockholders meeting and was present [illegible] the books found an entry showing that the company owed him $[illegible].

The last of the Kentucky national guardsmen [illegible] left Hopkins County were released Nov. 16. The principal source of trouble was the effort of the United Mine Workers to organize workers in the strip mines [illegible] belong to the Operators' Union. The operators oppose the U. M. W. efforts and discharge men as fast as they join the miners' organization. Disorder has been threatened several times, but the situation now is such that local officers can handle it.

The W. G. Duncan Coal Co. at [illegible] will install a 3,000-kw. steam turbine with condensers and auxiliary equipment.

Federal Judge A. M. J. Cochran, Covington, on Nov. 2 ordered the sale of the property of the **Liberty Coal Co.**, in Floyd County, to satisfy a judgment of $[illegible] secured by T. H. Morris, of Floyd County. John W. Menzies, federal court clerk, Covington, was named as receiver and special commissioner to conduct the sale. The value of the property is approximately $125,000.

Steady improvement is expected in the movement of coal cars into the Eastern Hazard coal field and that within a short time normal conditions will have been reached in mine operations. It is said that the L. & N. is now receiving 15 and 16 cars daily from the Cumberland Steel Co., and that at the present rate more cars will be given the two operators' mines. The road is also steadily picking up its idle cars on other roads and diverting them to these fields. Most mines of eastern Kentucky loaded more coal during the first half of November than they have loaded in a month before.

MICHIGAN

Following a talk on other matters at the twenty-fifth annual meeting of the Bankers' Club of Detroit, **Thomas R. Marshall**, of Indianapolis, former vice-president of the United States, outlined **the attitude of the Federal Fact Finding Coal Commission** of which he is a member. "It has neither thought nor purpose of being awed by influence or bought by gain," said Mr. Marshall. "It does not purpose to be suspicious nor censorious, but it does intend to see that it shall not be treated as though it were a court of law before which parties litigant are appearing, each striving to conceal some fact of advantage to the other man, and each seeking to cast discredit upon the other. It has been promised and we do believe, that it will receive the hearty assistance of both operator and miner in the effort to ascertain the truth."

MINNESOTA

C. P. White, federal [illegible] for the Northwest was at Duluth-Superior harbor recently on a [illegible] Mr. White felt optimistic as to the [illegible] but stated that anthracite [illegible] possibly be filled by water.

A Minneapolis coal company is advertising lignite coal as a profitable product and invites investment [illegible] tion notes running [illegible] ment suggests that a $[illegible] finance a car of lignite which will [illegible] immediate market, and will thereby [illegible] and handle another car and so on [illegible] the winter. Any amount [illegible] $10 up.

MISSOURI

A large coal field has been discovered at Mosby in Clay County. **The J. P. Drysdale Coal Co.**, of Davenport, Iowa, which made the first [illegible] has control of 1,000 acres. **The Mosby Coal Co.**, which was formed to exploit the new field recently, [illegible] and coal is now being loaded there.

The Higginsville Coal Mining Co. has changed its name from the **Hanover Coal Co.** and has [illegible] with a capital stock of $[illegible] by officers of the Kansas City and K. C. Odell Fuel Co.

Fire of undetermined origin recently destroyed the office, [illegible] building of the De Lay Coal Co. at Kansas City, causing a loss of $[illegible].

NEW YORK

Thomas Dickson, [illegible] Dickson & Tyler, New York, has been elected a director of the Brooklyn Trust Co. He succeeds the late Edgar M. Cullen, former Chief Judge of the Court of Appeals of New York State.

The City Club of New York and the **Women's City Club** [illegible] public meeting [illegible] Nov. 27. **Arthur S. Somers**, of Thomas Neale & Co., will speak on "[illegible] Crisis." The Rev. [illegible] will be presided over by **Thomas Kennedy**, [illegible] Whitney, of Hard & Rand, will give the views of coal [illegible] producers.

An audience of more than 200 [illegible] mining part engineers of [illegible] Pennsylvania

OHIO

The Hardwidge Coal Co.

The Wyoga Coal Co., Cadiz, capital $50,000. [illegible] and Charles J. [illegible]

The Lewisville Coal Co., Cincinnati, capital $50,000. H. D. Lloyd, Edward F. Kane, M. H. Harvey, F. F. [illegible] and Ryan Anthony.

The Guardian Coal Co. of Akron, capital $50,000. Harry S. Bailey is listed. Charles D. [illegible] and C. B. Baker.

The Brady Tucker Coal Co., Cincinnati, capital $[illegible]. [illegible] and Lee Bridge.

The Cascade-Salyards Coal Co., Dayton, has been incorporated with a capital of $15,000 by Howard Cassady, Herbert E. Cassady and others.

Seven hundred miners employed at the Walhonding mines of the **Cambria Collieries Coal Company** went on strike on the result of a conference in the mine in which general reduction of coal wages [illegible]. The miners refuse the proposed decrease in coal prices [illegible] the coal which was mined in the mine and which had been burned there was not paid [illegible] the new agreement [illegible] the difference between them and the miners was adjusted at a conference.

Four new coal offices have been opened in Cincinnati in the past two days, as follows: **The Calder Coal Co.**, representing West Virginia interests in the First National Bank building; the **Co-Operative Coal Co.**, in charge of a Cleveland operator, in the Dixie Terminal building; the **Regent Coal Co.** in the Pyramid building, and the **Valley Coal Co.**, a branch of the Wheeling concern of the same name.

President Tom Morgan of the Cincinnati Coal Exchange and retail manager for the Wolf Coal Co., is at Fort Myers, Fla., recuperating from an attack of pneumonia. This is the third time that he and wife have visited the winter resort.

With the installation of four elevators at Cincinnati on Oct. 1, the coaling time of locomotives on the Ohio River railway [illegible] the handling capacity. Every [illegible] will be equipped to [illegible] the new [illegible] and refueling [illegible].

Elmore Stebbins, for eight years with the Hocking Coal Co., has resigned and goes with the **Pittsburgh & Ohio Mining Co.**, of Cincinnati, in connection with the Cincinnati office of the Pittsburgh & Ohio Mining Co. Mr. Stebbins will be in charge of the Cincinnati office of the Pittsburgh & Ohio Mining Co., the latter having moved after the new company's lease at Lancaster for the same purpose, following completion of the former mine [illegible].

More than 1,000,000 tons of coal have been delivered on **Lake Erie** docks and dumped since Sept. 1. The [illegible] docks of the Interlake Iron Co. at the port of Lorain have a capacity of 1,000 tons an hour. Under the [illegible] agreement, the Lake vessels [illegible] Cleveland [illegible] a ton [illegible] Lorain [illegible] a ton.

Seventy-seven miners employed at the Wick mines of the **Jamison Coal & Coke Co.** [illegible] went on strike [illegible] a reduction in the rate [illegible] mining coal [illegible] Pittsburgh [illegible] Wick mines [illegible] Jamison [illegible] Pittsburgh [illegible] Wick [illegible] Jamison [illegible] Pittsburgh [illegible] Wick [illegible] Jamison [illegible] Pittsburgh [illegible] Wick

TENNESSEE

Announcement is made of the consolidation of the **Street Bros. Machine Works** and the **Patten Manufacturing Co.**, manufacturers of hoisting machinery. The charter of the Street Bros. Machine Works, Inc., will be expanded, and the products of the two companies will henceforth be manufactured and marketed by **Street Bros. Machine Works, Inc.**

UTAH

A great legal battle is expected soon in Utah following the **release under bail of the long list of coal operators** indicted by a grand jury in Salt Lake City in October, charged with conspiring to keep up the price of coal.

VIRGINIA

Norfolk domestic coal dealers who have complained to Alexander Forward, state fuel administrator, that they have been unable to obtain shipments of anthracite, have been informed by Mr. Forward that they may order direct from the mines 60 per cent of their last year's supply of this coal, and if shipments then are not forthcoming he will take up each individual case and get the shipments through.

Sale of the mines of the **Dex-Car Pocahontas Coal Co.**, at Twin Branch, W. Va., to **Henry Ford**, by the Dexter & Carpenter Co., will not interfere with that company's business in Norfolk, which is in charge of **H. T. Tengle**. The company will get supplies for its Hampton Roads trade from other sources.

WEST VIRGINIA

Matters have reached a point in the Kanawha and Logan fields where it will be necessary, according to operators, for them to ask that they be released from their agreement not to **charge more than $4.50 for prepared grades** or else be given a larger supply of cars. Mines are not working more than two days at the most and many of them not more than one day a week, and operators contend it is out of the question for them to produce prepared coal and sell it at $4.50.

The Pocahontas Fuel Co. has added to its holdings in the southern part of West Virginia by acquiring additional smokeless coal land and additional plants. It has completed negotiations for the purchase of the **Bottom Creek Coal & Coke Co.**, in which George and Samuel Patterson and others have been interested. The center of operations of the Bottom Creek company has been at Vivian. The Pocahontas company is controlled by Isaac T. Mann and associates.

Not only have the **Henry Ford interests** purchased the mining properties of Dexter & Carpenter at Twin Branch, these being among the largest shipping mines in the district, but there is also a report in circulation to the effect that the same interests **contemplate the purchase of other mining properties in Tug River District** and also the purchase outright of a large tract or tracts of mineral lands in the same district.

Pennsylvania and West Virginia coal men have launched the **B. R. & P. Coal Co.**, which is capitalized at $50,000. Headquarters will be at Fairmont. Leading figures in the new company are: James A. Berns, George Palmer, of Fayette City, Pa.; John D. Richmond, of Watson; Frank Bettegar, of Labelle, and E. C. Frame, Fairmont.

The Kellys Creek Colliery Co., Ward, is building a $70,000 amusement hall. The company is building concrete sidewalks and expects to have the camp connected with Charleston with hard roads soon.

Refuting the statement made by Fred Mooney, secretary-treasurer of District 17, U. M. W., that martial law and the opposition of officials of the state were responsible for the failure of the strike in Mingo County, **George Bausewine, secretary of the Williamson Coal Operators' Association** declares that the strike simply simmered out and was lost because at no time were many of the miners in the Williamson field really interested in its outcome. Less than half of the 5,000 to 6,000 miners who were working July 1, 1920, heeded the call to lay down their picks and shovels. The contempt that the radical element showed for law and order was astounding, and it was little wonder that the nation's papers reached out for the news. Soon special correspondents flooded the field. Then the union, ever alert to the power of publicity, sent in its propagandists. The tent colonies provided the "sob story" that sold the strike to the sympathetic and brought golden tears from sympathizers in New York, Boston, Baltimore and elsewhere in the East.

The E. E. White Coal Co. has awarded the contract for the construction of a modern steel tipple at its plant at Glen White. During the work of constructing the new tipple there will be a minimum loss in connection with present operations.

The fire which broke out several weeks ago in the mine of the **Anchor Coal Co.**, at High Coal, has been extinguished and it has been possible to resume operations on the usual scale. The fire when discovered was isolated, under the direction of inspectors of the department of mines, by building four concrete stoppings.

A temporary injunction has been granted to the **Nuttallburg Mining Co.**, in which Henry Ford has a controlling interest against the **Maryland-New River Co.**, which operates adjoining the Nuttallburg mine. The purpose of the injunction is to restrain the defendant company from removing certain barriers which it is claimed will cause the flooding of the Nuttallburg mine. It is stated that the Maryland company's work has been undertaken with a view to draining the flooded Rosedale section of its mine.

More coal was loaded in the Logan field during the first ten months of 1922 than during any similar period in the history of the region, the total reaching 11,103,450 tons. The previous high-water mark had been reached last year when 10,607,110 tons were loaded between Jan. 1 and Oct. 31. Under conditions such as prevailed during the first six months of the year, it would have been possible, it is believed, to have reached a total of 15,000,000 tons during the year. Under conditions now prevailing, it is believed that the total output of the field will reach 13,000,000 tons.

Litigation pending in the courts for five years between Alex R. Watson of Fairmont and the **Buckhannon River Coal Co.**, a Uniontown, Pa., concern operating at Adrian, has been settled by a decision awarding $25,244.27 to Watson, for breach of contract. The plaintiff contracted with the defendant company in 1916 for 50,000 tons at 95c. a ton but only secured the delivery of 36,000 tons. When the price of coal began to go up and he was unable to secure the delivery of the balance he made the defendant company a proposal to accept half the profit on the 14,000 tons remaining undelivered. That proposal the defendant company rejected. The judge of the Upshur Circuit Court held that he was entitled to half of the profit made by the defendant company on the sale of 14,000 tons on a basis of $1.40 per ton.

The Blue Ridge Collieries Co., of Cincinnati has been organized as a West Virginia concern. It proposes to issue 15,000 shares without par value. **Active in** effecting an organization of this company were: N. C. Kelley, Richard M. Lambert, Lyman H. Dreibach, Calvin S. Cramer and Arthur W. Gordon, all of Cincinnati.

Action taken by the stockholders of the **Pittsburgh-Wheeling Coal Co.**, in increasing the capital stock of the company from $100,000 to $250,000 has been approved by the secretary of state and the increase made effective.

Further development of coal land in the Northern Panhandle is presaged by the organization of the **McMechen Coal Co.**, which has a capital stock of $[illegible]. This company will have its office at McMechen. Largely interested in the new concern are C. W. Caldwell, C. D. Martin, J. F. Young, Michael Freeman and E. L. Parriott.

A most **successful safety meeting was** held at the Ida May mine of the **Consolidation Coal Co.** about the middle of November over which W. J. Wolf, superintendent of the Consolidation, presided, extending to the State Department of Mines his appreciation for its co-operation in having taken inspectors most in the safety work.

Until there is a better outlet from the western Greenbrier field of West Virginia and a better connection with the main line of the Chesapeake & Ohio development of the field in question will be materially retarded. The product is shipped over two roads, the Greenbrier & Eastern, completed about a year ago, and the Kanawha & Michigan railroad. Owing to transportation difficulties, mines on the Greenbrier & Eastern are limited to an allotment of 10 cars per day. One company alone in the new field is capable of producing more than the allotment of the whole field. There is a movement on foot to have the C. & O. make a direct connection with the Greenbrier & Eastern over the Hawks Nest route to Meadow River.

The Ohio County Fuel Co., of Pittsburgh, has been organized as a West Virginia corporation. Leading figures in the new company are: Horace H. Lamb, Mont W. Lamb, Horace H. Lamb and Thomas Balsley, all of Wheeling. Mr. Lamb is located at 13 Broadway, New York.

A number of strikers who participated in the mine riots at Short Creek and Barton and Franklin were sentenced on Nov. 14 by Judge Frank G. Wagoner in the circuit court at Cumberland. Francis R. Kaever, Allen Yates, James E. Miller, David A. Murphy, Edward Hazel and Douglas Truly drew sentences of six months in the house of correction for unlawful assembly. A number of others were convicted and sentenced for participation in the riot. Judge Wagoner in pronouncing sentence scored those who did not appear for trial but who incited the miners.

The Stanley Coal Co., with principal offices in Morgantown, has been incorporated by C. W. Ross and Stanley Ashby of Crelin, M. L. S. Kendall Jr. and John W. Kendall, Morgantown, and F. L. Kendall Jr., Pittsburg, with an authorized capital of $[illegible] to operate in Monongalia County.

CANADA

F. W. Osborn, representing the Yorkshire Trust Co., Vancouver, and A. P. Gardo, mining engineer of Prince Rupert, **are investigating the results of the diamond drilling** operations which were done by order of the court on the coal areas in the Copper River district owned by the **defunct National Finance Co. of Vancouver**, with a view to obtaining an order from the court to renew the operations in the spring. The coal areas are said to be the last single asset of the defunct company. Last spring an expenditure of $[illegible] in exploration work was required.

The U. M. W. will attempt to invade the northern Alberta field, which in the past has been an entirely open-shop district. A mass meeting was held at Edmonton on Nov. 15. Operators are showing no particular alarm over the movement. They state that the mines are well laid out, are armed of constant employment, and are non-unionized, and that have no fear that the movement will succeed.

Prof. F. A. Thompson, of the Idaho School of Mines, recommended the **American Mining Congress** at a meeting of the British Columbia Division of the Canadian Institute of Mining and Metallurgy, Nov. 15-18.

According to a report issued by the **Dominion Bureau of Statistics**, the total **number of coal mines in Canada in 1921** was 698, the aggregate length of the underground workings [illegible]. The total capital investment was $[illegible] and the output was [illegible] tons, the value of [illegible]. The total number of employees was [illegible], who received in wages $[illegible]. The number of days worked was [illegible], or an average of 228 days for each mine, [illegible] average wage was $6.24 per day. Including employees receiving [illegible] received a total of $[illegible] and [illegible] for mine timber, amounted to $[illegible].

The Dominion Bureau of Statistics has issued a summary of **imports and exports during the first ten months of the year** as given below. Imports from Great Britain show heavy increases as compared with the first years.

CANADIAN EXPORTS AND IMPORTS

	[illegible]	[illegible]
Anthracite imports	[illegible]	[illegible]
Bituminous imports	[illegible]	[illegible]
Coal exports	[illegible]	[illegible]

Alexander Dick has been appointed [illegible] engineer of coal mines and **E. F. Merritt** as general manager of coal mines for the **British Empire Steel Corporation**. Mr. Dick was general mine agent of the Dominion Coal Co. He had previously been engineer of the Coal Commission, with the formation of the new company, when he became its acting coal mines chief. Mr. Merritt for the past three years has been general manager of the Dominion Steel Corporation at Sydney.

The first cargo of hard coal for the use of Port Arthur this season has arrived at that port via the Panama Canal. The cargo was a load of coal from Buffalo consigned to the Welsh Coal Co.

WASHINGTON, D. C.

Coal Dust Explosion Tests to Prevent Mental Mine [illegible] [illegible] report by Dr. [illegible] of the Bureau of Mines [illegible] the Bureau's experiments in connection with the explosion of [illegible] A. Gorgas, who as chief engineer of the Bureau of Mines directed the experiments, is a [illegible] report of a series of tests conducted by the Bureau of Mines at the Pittsburgh [illegible] Bureau of Mines [illegible] in connection with the [illegible] Association.

Association Activities

Clarksburg Coal Club

Monongahela Coal Association

West Virginia Coal Association

Publications Received

Annual Report of the Department of Mines of West Virginia for the Fiscal Year [illegible] by H. M. Lambie, Chief of Department of Mines. Pp. 414.

Report of the State Mine Inspectors of Iowa for the Calendar Year Ending Dec. [illegible] by W. L. Holland, R. T. Rhys, [illegible] and L. M. Sharon. Pp [illegible].

Coal Statistics for Canada for the Calendar Years 1919, 1920 and 1921. Dominion Bureau of Statistics, Mining, Metallurgical and Chemical Branch, Ottawa, Canada. Pp. [illegible]. Covers coal consumption, production, exports, imports, number of employees, etc. This report is a continuation of the series of annual reports previously published by the Department of Mines on the production of coal and coke in Canada.

Obituary

C. G. Blake, president of the C. G. Blake Coal Co., pioneer shippers and agents for New River coals, died at his residence in Cincinnati on Nov. 3. Mr. Blake was born in Terre Haute, Ind., seventy-five years ago and came to Cincinnati in 1870, where he engaged in the pig-iron business. In 1886 he disposed of his holding in that trade and entered the coal business with Richard and Frank Ellison. A second incorporation of the firm under its present style admitted E. A. Colter, one of the leading figures in Cincinnati's coal trade. Mr. Blake took pleasure in recounting the fact that he was one of the first persons to ship New River coal west. With the growing importance of that field his company expanded and became large handlers and shippers of coal to foreign ports. Mr. Blake laid much of the ground work for this enterprise himself.

Col. Jay H. Northup is dead of paralysis at Louisa, Ky. He was long active in coal, timber and railroad industries. He opened the Big Sandy region to capital and later founded a model farm. He was a lieutenant in the Union Army.

Traffic News

The Pittsburgh & West Virginia Ry. Co. and eighteen coal operators whose mines are located on that road, have filed a complaint with the I. C. C. asking that a **physical connection at Hopedale, Ohio, between** that road and the **Alliance Division of the New York Central**, be made mandatory. Recently, due to lack of power and other adverse operating conditions, the P. & W. V. is said to have been utterly incapable of handling the volume of traffic offered it. The New York Central has declined to make the connection voluntarily on the ground that traffic is not sufficient to justify the expenditure, not only of the connection but of the enlargement of terminal and handling facilities which the increase in traffic would necessitate. It is alleged that the New York Central also is fearful that it would be short-hauled on Pittsburgh [illegible] traffic.

In the complaint of the **Jeddo-Highland Coal Co.** an examiner recommends that rates on [illegible] run of mine and culm coal from mines and culm banks of the Lehigh Valley R.R. in the Lehigh region of Pennsylvania to breakers in this region for preparation and re-forwarding by that road during federal control, were unreasonable because they exceeded those established Aug. 26, 1918.

A proposed report by Examiner A. S. Worthington of the I. C. C. in the case of the **Kanawha Black Band Coal Co.** vs. the **Chesapeake & Ohio Ry. Co.**, finds rates on coal or carbonite from certain mines on the Kanawha District to interstate destinations on the C. & O. and its connections are unreasonable and unduly prejudicial. Reasonable and non-prejudicial rates are prescribed for the future.

Recent meetings of operators in West Virginia [illegible] for the purpose of **securing some relief from car shortages** and other transportation handicaps led to a general conference of representatives of the various coal fields of the state and operators of the C. & O. at Huntington. The conference was held specifically for the purpose of discussing the question of car supply on the main and branch lines of the road.

Headway was made toward a better understanding between the railroad and the operators. It was pointed out by the road officials that every effort was being made to get motive power and coal-carrying equipment in better shape.

Wyoming's railroad mileage is about to be reduced twelve miles. The branch line from Lost Springs to the Rosin coal mine, twelve miles distant, is to be scrapped by the Chicago & Northwestern.

As a result of a ruling by the railroad commission of Wisconsin, a **reduction of 10c. a ton** on freight charges on soft coal **from Milwaukee and Sheboygan to Oshkosh, Wis.,** has been made. Formerly the rate was $1.10 per ton.

A reduction of 10 per cent in the short-haul intrastate coal rate has been ordered by the **Indiana Public Service Commission.** The short-haul rates affected are all hauls of 30 miles or under. The reduction goes into effect Dec. 1. The reductions ordered affected certain classes of rates that were not decreased in the general freight rate reductions of a few months ago and will now bring these classes down to the level of the rest of the freight rates on coal. The case was pressed by the **Indiana State Chamber of Commerce.**

At a recent meeting of the Monongahela Valley Association the question discussed had to do with reference to the recommendation of a representative of the I. C. C. that the minimum local rate for moving coal in West Virginia should be 84c. instead of 64c., the present rate. The decision reached as a result of such discussion was that each chamber of commerce in the Monongahela Valley should file an intervening petition with the I. C. C. and that the association on its own part should also file an intervening petition so that the association may be a party to the hearing to be held in Pittsburgh on Dec. 4.

Trade Literature

Solid Bronze Centrifugal Mine Pumps. Allis-Chalmers Mfg. Co., Milwaukee, Wis. Leaflet No. 2060. Four-page folder, illustrated. These pumps are particularly designed to resist the acidulous and erosive action of mine water.

Supplies and Equipment for Coal Mines. Cooke-Wilson Electric Supply Co., Charleston, Pittsburgh and Athens. Catalog No. 4. Pp. 381, 6 x 9 in.; illus. Covers a wide range of electrical supplies for coal mines and contains a fund of useful information.

R. D. Nuttall Co., Pittsburgh, Pa., has issued a new booklet No. 36 containing a **series of charts on gear design,** also bulletin No. 34 on **industrial helical gears.**

Padley & Venables, Ltd., Sheffield, England, List B, Section 2, describing the Hollow and Solid Rock Drills, and List B, Section 3 on **Coal Cutter Picks.**

The Combustion Engineering Corp. of New York City has published a booklet entitled "**Service**," by John Van Brunt. It gives the stoker manufacturer's standpoint on the subject of service.

Coming Meetings

The Illinois Mining Institute will hold its next meeting Dec. 1 and 2 at the Illinois Union Bldg., cor. Wright and John St., Champaign, Ill. Secretary, Martin Bolt, Springfield, Ill.

West Virginia Coal Mining Institute's annual meeting will be held Dec. 5 and 6, at Huntington, W. Va. Secretary, R. E. Sherwood, Kanawha Bank Bldg., Charleston, W. Va.

Coal Mining Institute of America will meet Dec. 13, 14 and 15 at Pittsburgh, Pa. Secretary, H. D. Mason, Jr., 911 Chamber of Commerce Bldg., Pittsburgh, Pa.

National Exposition of Power and Mechanical Engineering will be held at the Grand Central Palace, New York City, Dec. 7-13. Manager, Charles F. Roth, Grand Central Palace, New York City.

COAL AGE

The Only National Paper Devoted to Coal Mining and Coal Marketing

C. E. LESHER, *Editor*

Volume 22 NEW YORK, THURSDAY, NOVEMBER 30, 1922 Number 22

What Every Coal Man Knows

THAT if the railroads were now to supply all the cars and transportation ordered by the soft-coal mines—to reduce "car shortage" to zero—the coal producers would not only not be able to sell the coal that would thus be produced but would get a far lower price than now obtains for that which they did produce.

That with mines and labor ready to produce 13,000,000 tons and upward per week, with consumption less than 9,000,000 tons weekly and with stocks of bituminous coal in the hands of consumers now equal to, if not in excess of, thirty days' requirements, a gain of a million tons per week in production would flatten out the soft-coal market to a distressing position.

That, in fact, the car shortage is the only thing that sustains the price of soft coal, and that in spots it is not even doing that.

In the week of Nov. 4 the railroads reported to the American Railway Association that 412,679 cars were ordered by the bituminous-coal mines for current loading. These, if supplied and loaded, would have given an output of more than 20,000,000 tons, or twice the actual output that week. This figure doubtless represents the present rating of the mines, and as everyone knows that the ratings are inflated no one will consider that the mines could have produced and loaded that quantity of coal had the railroads been able to supply the cars.

Cars placed—that is to say, constructively placed, for every car that is held over either empty or under part load is counted each successive day—numbered 220,039, according to the same authority. This represented 53 per cent of the orders; the car supply was therefore but 53 per cent. For the same week the reports to the Geological Survey of time worked and lost by causes at these mines showed Ohio and eastern Kentucky working less than 40 per cent of full time and other districts ranging upward to Alabama at 82 per cent. The average for the country was around 43 per cent, and of the more than half time lost the greater part was attributed to transportation disability or "car shortage."

Instead of this obviously inflated base on which to calculate the extent of the railroads' shortcomings, let us compare the present rate of production to the maximum recorded weekly output of bituminous coal, 13,000,000 tons. There can be little doubt but that were production to mount to 13,000,000 tons per week the demands of all consumers would soon be satisfied. In fact such an output would rapidly meet all needs, for it would put something over 2,000,000 tons more per week into stocks and thus double the rate of accumulation of reserves. The present weekly output is 82 per cent of that maximum, and the car supply, measured in a more reasonable manner, is thus 82 per cent and not 53 per cent.

The railroads are now exceeding all previous records in loading freight of all kinds, between 900,000 and 1,000,000 cars per week being the usual thing. They could boost the bituminous-coal production to 12,000,000 tons per week and higher were they willing to make the effort. There have been in effect priority orders affecting the supply of transportation for this commodity that if followed by the railroads would have brought this result. Previous high records of coal loading always have been reached through the imposition and strict application of such priorities. Objection to literal observance of priorities of this nature is found in the consequent denial of transportation to other commodities such as ore, limestone, steel products, building materials, and even anthracite, that move in open-top equipment. Many of these other offerings are better revenue producers than soft coal. Possibly the railroad officials have an eye on the general situation and consider that coal will move next week if not this, while some of the other kinds of freight might not. This year coal has not had its normal share of the transportation.

It is quite true, as continually pointed out by the coal operators and mine workers, that lack of transportation alone holds down production during periods such as this autumn, when the consumers are demanding large tonnages. It is also true that while the demand for coal at any given time may be twice the current rate of production the total requirements in a season are limited and there never has been a year, save 1916 and 1917, the end of which did not see the demand well satisfied. From the date in August when the strike was settled to the end of 1922 there will be produced about 190,000,000 tons of bituminous coal. It is being produced at an average rate of between ten and eleven million tons per week. If the railroads had been able in August and September to supply the transportation it would have poured forth at 15,000,000 tons per week for a few weeks. At that rate every stockpile would have been overflowing in four weeks and the demand and output of soft coal would have dropped to around 9,000,000 tons and the price would have been like unto last March.

We in this country can have peakload transportation for 13,000,000 or 15,000,000 tons of bituminous coal per week without a car shortage if we are willing to pay for it. But since the requirements for such tonnages are spasmodic and of short duration, coal-freight rates would have to carry the charges sufficient to support the capital investment necessary to supply the additional equipment and facilities. This might conceivably add from 25 to 50 per cent to the coal freight rates. The railroads would add nothing to their total tonnage carried by such a program.

On the other hand the country pays for the lack of sufficient transportation during periods of peak demand by paying more for spot coal. A measure of this is found by comparing the average realization of the bituminous-coal operators, as reported by the Geological

Where the Inefficiency Lies

OUR contemporary the *Gas Age-Record* in a recent issue comments editorially on the "inadequate organization [the Geological Survey] now employed to collect and distribute coal statistics" and deplores the fact that it is not possible "to take the figures given out by the Geological Survey, and draw definite and accurate conclusions." It appears that the *Gas Age-Record*, like a host of others, including ourselves, is surprised at the volume of stocks of bituminous coal in the hands of consumers, as reported recently by the Survey. Having taken the reported stocks of coal as of last April, added current production and subtracted estimated consumption week by week, the *Gas Age-Record*, like the rest of us, found that by the time the strike was ended, in August, the reserve of coal was something less than zero.

None but amateur calculators took this conclusion seriously. Informed observers noted as early as the middle of July that there were other factors involved than were currently reported in the Survey's weekly reports. The market was entirely too steady for there to be such a paucity of coal. The figure reported as of Sept. 1, 22,000,000 tons, is higher than we expected, but the unknown factor, coal in transit, on which data are now available, explains the result.

The editor of the *Gas Age-Record* does not want to reflect on the "distinct service" rendered by the Survey in its weekly report, but does charge it with inefficiency. The inefficiency is, we believe, on the part of those who use the figures, or rather overuse them. We have extrapolated these figures ourselves and have missed the mark at times, but never so far that we were moved to seek an alibi by assailing the source of the data, the accuracy of which we were not disposed to question.

Coal Cost in Relation to Water Power

A SUGGESTIVE thought was expressed recently by Dr. Charles P. Steinmetz with respect to the influence of the cost of coal on the development of water power. After pointing out that in New York State there are developed water powers producing energy equivalent to 10,000,000 tons of coal as compared with an annual total consumption in the state of 54,000,000 tons, he notes that there are undeveloped water powers capable of saving 34,000,000 tons of coal.

California has 1,150 kw. of hydraulic energy per capita as compared with 185 kw. of fuel power. New York has 277 kw. of hydraulic power and 105 kw. of fuel power according to Dr. Steinmetz. California has no coal and what is imported comes from great distances and is costly. New York has always had cheap coal for industry. The Western state has had a powerful incentive for developing her water power and the Eastern state has not. It is pointed out that the cost of coal in New York is now as high as it was in California when that state forced the development of hydraulic power.

The high initial cost of installation of water power is what has held it back, but when that is offset or more than balanced by a high price for coal, capital investment turns to the rivers and coal loses a permanent market. The change will be gradual, but we agree with Dr. Steinmetz that it is sure. It does not follow that the consumption of coal will in consequence become less, but rather that it will not grow with the industrial development of the country. Water power can never supplant the use of coal in its entirety, even for supplying electrical energy, for the relative costs always tend to equalize and local conditions must always have a powerful influence on the choice between the two basic sources of power.

Can Soft Coal Retain Domestic Trade?

ANTHRACITE operators are frankly concerned over the possibility that forced substitution of other fuels for hard coal this winter will make permanent inroads on their business. It has been twenty years since the East has lacked hard coal to meet its household requirements. The Easterner is not now particularly pleased when he is required to take bituminous coal and he is but slowly heeding the advice that he do so, at least to the extent of protecting his early requirements.

On the other hand, there are those bituminous-coal producers in the high-grade fields nearest to the Atlantic seaboard who have for years looked longingly at the steady, dependable market enjoyed by the producer of domestic sizes of anthracite. He has wanted to introduce his product in competition, as the hard-coal seller has sought to push his steam sizes on the markets of the soft-coal man.

Because bituminous coal has never participated in the household trade of the East, bituminous coal has not, save in exceptional instances, been prepared for that market. The result now is that when the soft-coal shippers are called on to help fill the gap caused by the strike in the hard-coal mines they have nothing but run-of-mine to ship. Straight run-of-mine coal is not a satisfactory household coal. No one likes to use it. Hotels, office buildings and apartment houses with fully equipped steam plants can and do take mine-run coal, as in Chicago, where run-of-mine smokeless coal is the favored fuel. But the householder wants sized lumps. If the bituminous-coal producer has a desire to retain any of the market now thrust upon him he must cater to that market. Several of these producers have announced the installation of equipment for sizing their product, and the indications are that others will follow. Some of the central Pennsylvania coals will not lend themselves to this treatment, being too friable, but others have already been proved to be real household coal.

The present is an opportunity for the soft-coal men so situated that they can ship into the Eastern territory. Having matched preparation with anthracite, they will have lower price to set against cleaner, smokeless product, shipped from mines that never have car shortage.

Coverdale Mine to Hoist 4,000 Tons per Day Is Fitted With Two-Car Self-Dumping Cages

Disadvantage of Skip When Tonnage Is Under 5,000 Daily and Shaft Depth Moderate — How Cars in Single File Form "Twos" at Shaft and Enter Single File Beyond

By A. F. Brosky*
Pittsburgh, Pa.

UNLESS a speed is attained both dangerous and undesirable, 4,000 tons of product cannot be raised satisfactorily in cages in an eight-hour day up a two-compartment shaft, even though that shaft be of only moderate depth. It may be said that the end may be attained by putting two cars in tandem on a single cage, thus increasing the capacity of the shaft.

Unfortunately, though it is easy to arrange to put two cars end for end on a cage, when it is done they cannot be made self-dumping, and time will be lost spotting the cage at the landing, pushing the cars off the cage and either loading other empty cars in their stead or dumping the cars as received and backing them onto the cage. Furthermore with the decaging and dumping arrangements two more men must be employed. The suggestion may be made that cages with two or more decks each lifting one car might be used and indeed they have been tried, but it has been found that too much time is lost in caging and decaging.

Unless 5,000 tons is to be raised per shift skip hoisting is not desirable, though it might be a preferable method of handling coal at great depths. It brings a large tonnage up whenever the mine bottom is filled and it would overburden any tipple that was designed to prepare and load an output under 5,000 tons per shift. The maximum efficiency of a skip is realized only when it is operated at a fair speed. To handle the load of coal that is brought up a shaft whenever a trip brings a string of cars to the bottom, the tipple must be run at overload with resulting poor preparation or else the speed of hoisting must be stepped down to the rate of preparation for which the tipple was designed.

Increased tipple capacity to cope with high-speed hoisting under the conditions stated is not desirable as there then would be idle periods between trips. It is a different matter with 500-ft. shafts or deeper. In that case skip hoisting is ideal for tonnages of 4,000 or even less, depending upon the depth, as much time is consumed in raising the coal from the bottom to the dump plate.

In a shaft of moderate depth and with a 4,000-ton output only one of the many advantages which skip hoisting affords—the ability to use gateless mine cars—is retained, but this advantage is offset by the complexity of the equipment with which the shaft bottom must be provided. The skip hoist is primarily to aid in the rapid lifting of great tonnages up a single shaft of moderate depth or moderate tonnages up a single shaft of great depth.

Four thousand tons of coal may be hoisted successfully by another means—namely, through the employment of a cage holding two cars placed side by side in conjunction with a four-track bottom. Such an installation has been in successful operation for several years at the mine of the Monroe Coal Co. at Sevier, Pa., and one installed more recently at the Coverdale mine, as

Note—The headpiece shows the [illegible] mine tipple. The tank, of unusual shape mounted on four legs in the rear of a small brick building on the extreme right, is a gravity-fed cooling tank for water circulated around the crosshead bearings and engine slip regulator by a small centrifugal pump.

No. 8 shaft of the Pittsburgh Terminal Railroad & Coal Co., is working equally well. This mine is 12 miles south of Pittsburgh and has approximately 3,000 acres of the Pittsburgh seam, the deposit being about 9 ft. thick. The property was opened up only a few years ago, and much development work has yet to be done. In consequence only 1,000 tons of coal is now being hoisted in each eight-hour day, but the ultimate daily output will aggregate 4,000 tons.

The depth of the shaft is 340 ft. The distance from the concrete coping to the point of discharge is 65 ft., so the total lift is 405 ft. The inside dimensions of the shaft are approximately 11 x 26 ft., the unusual width being necessary to accommodate the Lepley cages, each carrying two 2-ton mine cars side by side. The cages are self-dumping and differ but little in operating principle from the single-car type, the tipping and locking guides and other devices being practically the same in each. In order to carry safely the heavier loads resulting from hoisting two cars in one lift the cages, which measure 10 ft. 6 in. x 12 ft., are more heavily constructed than is usual. The 16-ft. head sheaves also are heavier than in most headframes. They carry a 1¼-in. rope and are mounted on a 10-in. steel shaft. The headframe itself is more substantial than that which is provided at most mines. Heavy headframes are sometimes made up of fabricated columns cross-latticed, but the headframe over the Coverdale shaft is composed of six solid-sectioned columns for posts and two for the inclined compression legs, all of which are securely batter-braced.

Before giving details of the main shaft bottom it might be well to describe briefly the method of mining as regards the immediate and future recovery of coal, the underground layout and related facts. A rectangular block of coal is left about the shaft bottoms for protection. The greater dimension of this rectangle is in the direction of the face entries, which lie north and south—the usual direction of such workings in the Pittsburgh seam. The main bottom entries are not driven at 90 deg. to the main face entries, as is frequently the case, but on an angle of about 70 deg. The surface topography, railroad needs and the elimination of excessive cutting and filling influenced the location of the shaft and main bottom entries. They are so placed as to allow an incoming motor with a load trip to uncouple and pick up the empty trip with a minimum of confusion and delay. This feature will be described elsewhere. The double entries connecting the supply shaft with the main shaft are approximately 1,100 ft. long and lie at 90 deg. to the load and empty tracks on the main bottom and parallel with the spur railroad track on the surface. The surface topography fits in well with the shaft locations and affords an ideal sur-

FIG. 1. MOUNT AND VILLAGE OF THE COVERDALE, OR NO. 8, SHAFT OF THE PITTSBURGH TERMINAL RAILROAD & COAL CO.

A stream flow between the hoisting shaft and the village. This isolation has its advantages in keeping people from congregating around the mines and children from playing on the railroad tracks. The valley will in time, however, be filled with rock by means of a larry with distributing conveyor

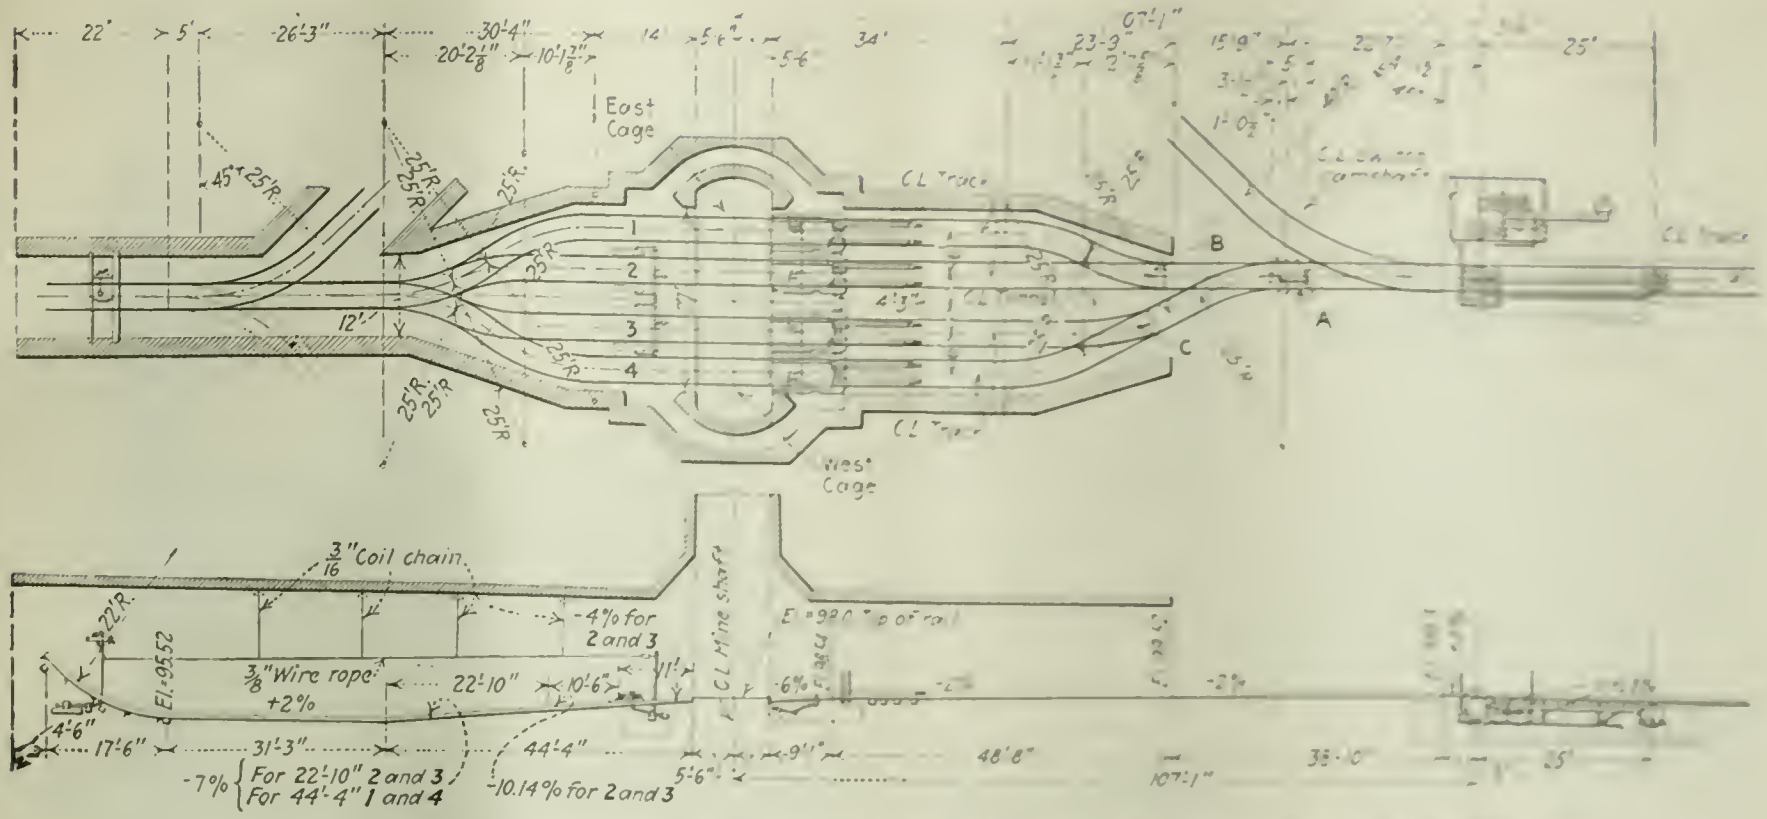

FIG. 2—SHAFT BOTTOM WITH FOUR TRACKS LEADING TO AND FROM TWO CAGES

The switches provide automatically that the cars will go to the proper track. The [illegible] in the left of the illustration releases the cars on the empty track one by one, so that they do not collide but take the empty pit in such order as to avoid one another, without however occasioning any undue delay.

face-plant layout. All this may be noted in Fig. 1, which shows a portion of the mine map upon which are superimposed a few of the surface buildings. It will be noted that a low-lying basin separates the town proper and the area occupied by the surface plant, and that the bottom of the depression passes close by the supply shaft. The town itself lies on a hill that flanks the eastern edge of the basin. This natural hollow is a benefit in two ways. It partly separates the town from the plant and affords a convenient dumping ground for the refuse rock from the mine.

The men traveling from the town to work and returning therefrom keep throughout their journey on the opposite side of the valley from the tipple and main shaft and do not come anywhere near either. In this way the men at work at the main shaft are free from the interruption of passing and loitering men.

A Heyl & Patterson refuse-stacking car disposes of the slate. The slate track passes under the rock bin on the tipple and skirts the edge of the hollow approximately parallel with the railroad track. The conditions are such as to favor easy slate disposal at low cost because of the short haulage and straight track.

Air and Main Shafts Over Thousand Feet Apart

As already has been mentioned, the auxiliary or air, shaft is 1,100 ft. from the main shaft. Ordinarily the shaft for lowering men is placed close to the one up which coal is hoisted. Surface management is facilitated by the grouping of its several structures as close together as possible and certainly closer supervision is obtained, but the arrangement has the disadvantage that men will then occupy their time by "loafing" around the main shaft and tipple. Furthermore, in the early stages of development, mining activities are concentrated about the big bottom, consequently the miners have a short distance to travel to their working places, no matter where the main shaft may be. After development it makes little difference whether the men are lowered at a point near the big bottom or many hundred feet away. Few men work in the vicinity of the big bottom. Each plan has its advantages and disadvantages, but these do not entirely govern the selection, for surface features and other related factors have a direct bearing on the final plan.

The mine is laid out on the quadruple-entry system. At 2,000-ft. intervals two face entries are driven, and from these two butt entries are extended every 300 ft.

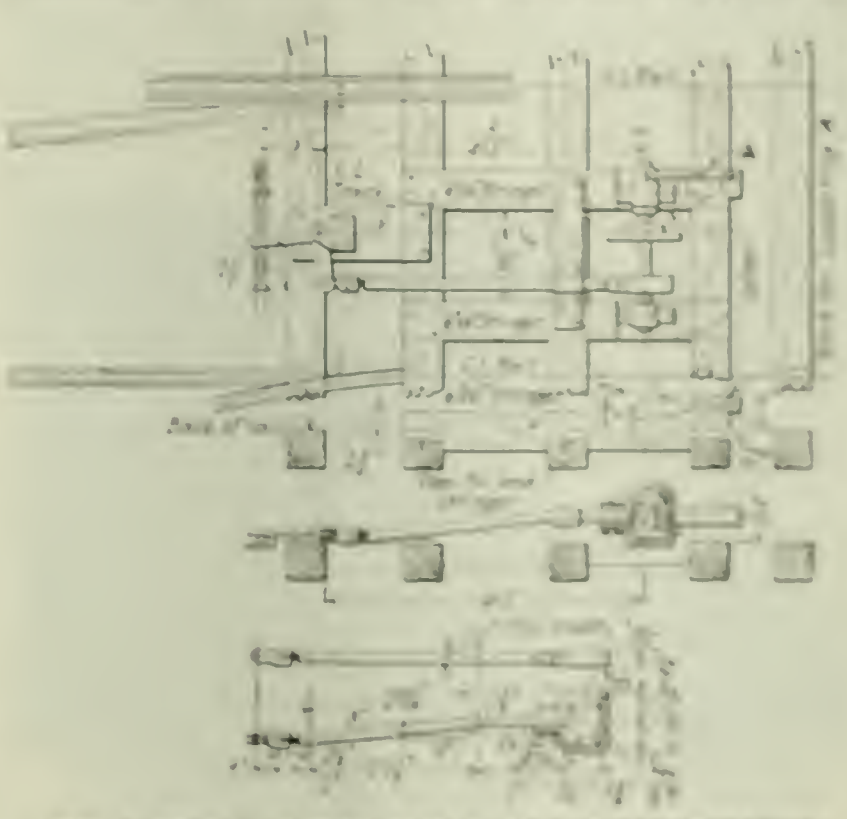

FIG. 3—TWO OF TURNEVILLE MULTIPLE-SPEED SWITCH

The operating principle is as follows: Two steel bars, pivoted together so as to form four spurs, are mounted [illegible] horizontal shaft from which projects a [illegible] This carriage within a square hood under [illegible] a connecting rod. As the two spurs [illegible] two positions at which it is operated [illegible] the switch. In one it presses on one side of the switch, putting the [illegible] rail forward and opening that portion of the [illegible] the other side of the switch, pulling the [illegible] closing the switch. These positions correspond to the positions of the cast steel. The automatic features [illegible] without effect. [illegible] opening cars [illegible] changing the switch points. The third rail [illegible] spur and open the switch. The latter will [illegible] the rear wheel [illegible] the switch [illegible]

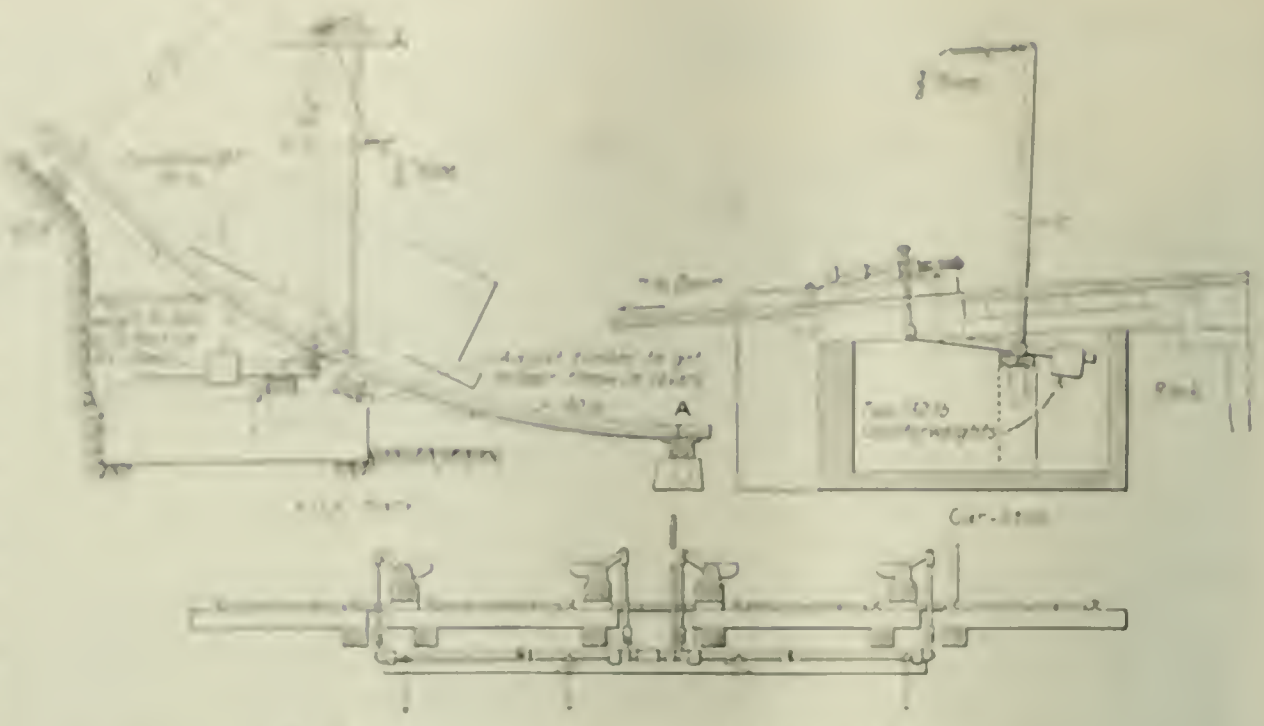

FIG. 2.—AUTOMATIC KICKBACK AND CAR STOP

The car rips on the kickback, and just about where it reverses, the rail, held up till that time by a counterweight, descends and actuates the car stop, which releases another car. This car arrives at the switch of the empty track almost immediately after the car from the kickback has passed out of the way.

The rise in this section must be allowed to stand at least till the entry is finished. When entry driving has been sufficiently advanced, activities will be shifted elsewhere.

The coal lies practically flat; in fact it is so nearly level that it has not been thought necessary to provide the mine cars with brakes. The haulage motor with a loaded trip pulls into the main bottom as far as a trip feeder. Here it is cut off and runs around to the empty-car entry. At this point it picks up its trip and without delay starts back to the workings. The trip of loads, which never exceeds fifty cars, is elevated, one car at a time, up a 1.5-per cent grade by a 25-ft. chain and hook trip feeder. From the knuckle of this feeder the cars drop down a favorable grade and through

automatic switches to the shaft. A plan and profile of the shaft bottom are shown in Fig. 2.

Cars in sets of two to passing through the first automatic switch at *A* are diverted alternately to the track leading to the east or west cage. Let us say that this switch is set to allow two cars to pass on to the east cage. The foremost of the two cars will be diverted either to the right or left track leading from *B* to the east cage, depending upon the setting of the wheel-thrown switches at *B*. Whichever track the first car passes over, its wheels throw the switch points at *B* for the opposite track, over which the second car passes. The next set of two cars in passing over the switch at *A* will set it so as to allow them to drop down to the west

FIG. 6—LOAD SIDE OF SHAFT BOTTOM

Looking toward the shaft. The illustration is made from a photograph taken on a day when the mine was idle. This accounts for four loaded cars being at the landing. Ordinarily there are only two, both on either one of the two sides. Note the well-concreted arch in the rear, the 12-in. beams in the foreground resting on a heavy side wall of pressed brick.

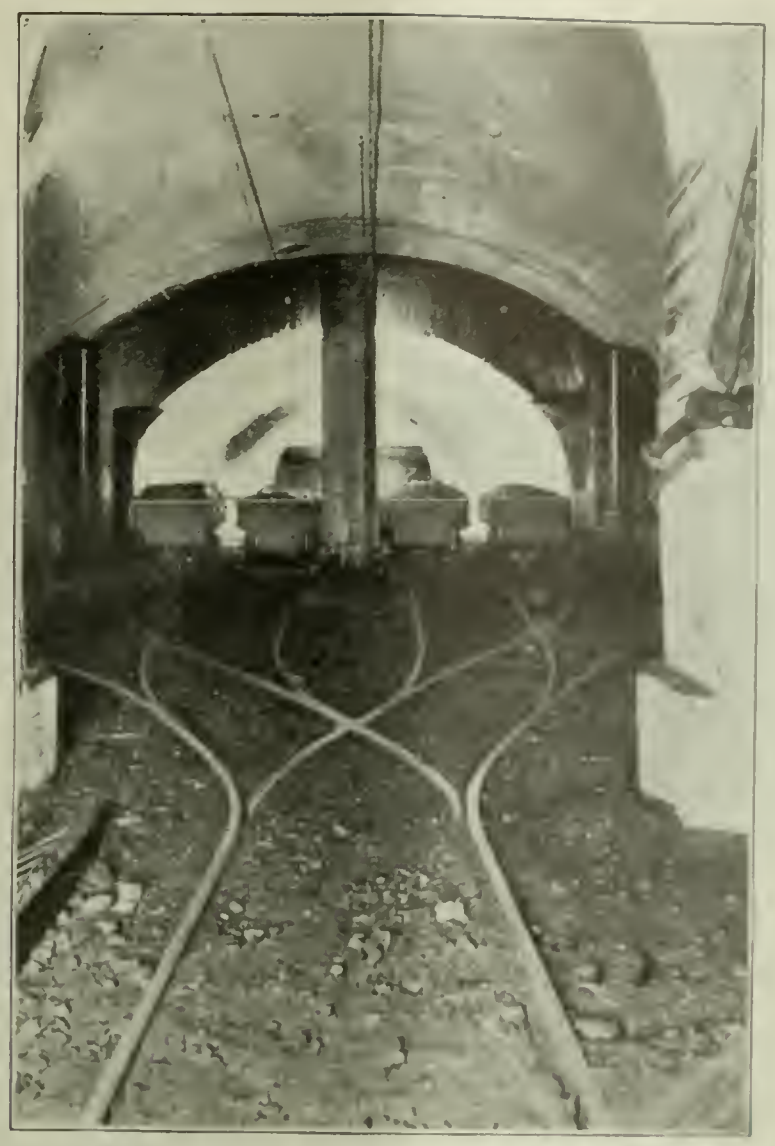

FIG. 7—EMPTY SIDE OF SHAFT BOTTOM

Looking toward the shaft. The empties (here shown loaded) drop down this grade of 7 per cent to a kickback to the rear of the point from which the photograph that this illustration reproduces was taken. The ropes seen along the roof connect the swinging kickback with automatic car stops located on the inner tracks.

cage, going through a similar switching device at *C* as is found at *B*. Reference to the illustrations, Figs. 3 and 4, and the captions thereunder will aid the reader in understanding the working principle of these two switches.

After passing the last switch points the cars drift down toward the cage. The grade to the cage is steep, so that the cars attain much speed on their way and must be slowed down and stopped. This is accomplished by four friction car checks, one on each track. These are of the usual type, consisting of a heavy wheel clamp of structural-steel held against each rail by strong steel-coil springs and operated from a point centrally located in front of the cages. These car checks are designed with provisions for the future installation of an air cylinder, so that eventually they may be operated pneumatically.

Upon being released from the car checks the two cars on the approach to the cage next to be landed drift down simultaneously to the cager, where they are held by horns until the cage descends into position. The cager, which is automatic in the setting and resetting of the horns at the cage landing and in raising and depressing the car stops that hold the cars on the cage, varies from the usual type only in its handling two cars instead of one.

The arrangement on the empty side whereby the two empty cars coming from the cage are passed to the empty storage track, however, is unusual. As the empty cars run off the cage the inner one will be held by a car stop and the end one is delivered directly to a pivoted kick-back that automatically releases the inner car from its stop after the first car reaches the kick-back. Sections showing the details both of the kick-back and the car stop comprise Fig. 5.

It will be seen from the drawing that the curved kick-back rails are held securely at gage by means of angle irons fastened on the bottom, or flange. The lower ends of these rails are pivoted where they join the level track at *A*. The car is shown in the illustration directly above a knife edge on the kick-back. The weight of the car when it approaches this point depresses a counterweighted lever arm to which is linked a vertical rod. This rod again connects with an L-shaped lever, which when acted upon by the vertical pull of the vertical rod causes it to pull on a horizontal rope that is attached to it. The other end of the rope is connected to the car-stop release. The depression of the kick-back is only sufficient to release the car stops. After the car has left it the kick-back is elevated by the lever action of the counterweight.

The car-stop mechanism is simple in construction and in operation. The rope from the kick-back connects with the upper ends of horizontally axled levers, to which are welded counterweighted lever arms. To the ends away from the counterweights on these levers are pinned vertical tie rods which when depressed cause the lugs that protrude out over the rail and in front of the car wheels to be swung into the clear. The released car then passes by gravity to the kick-back and the lugs fall back over the rail to catch the next inside car coming from a landed cage. The cars after leaving the kick-back are sidetracked to the empty-car entry. This equipment was furnished by Heyl & Patterson, Inc., of Pittsburgh, Pa.

The shaft-bottom equipment, although it appears to be complicated, is simple and positive in action. One begins to realize this only after having watched the operation in which a ton of coal may be raised every 8 seconds if so desired, and the cars fed, caged and uncaged by only three men, one of whom does the lubricating and inspecting of the mine cars and makes

FIG. 8—SHUTTLES FOR MAKING UP SHOTTON TRIP

FIG. 9

Motor-Generator Set

From left to right: induction motor, flywheel, direct-current generator and low-voltage exciter, all covered or at least guarded. The room also contains the controller panel, the slip regulator, the switchboard and other auxiliaries. The hoist is in an adjoining room. This is an example of well-guarded machinery. The mines are recognizing at last, and guarding against, the dangers of the power house and shops.

up the empty trip. Another uncouples the cars comprising the load trip and drops them to the trip feeder. The third man is the cager.

Another of the features of the Coverdale plant is the Ilgner-Ward-Leonard hoist installed at the main shaft. Incidentally it is the first of its kind in the Pittsburgh region. The load on the motor of a hoist is extremely variable. An inspection of a characteristic curve of load versus time of the average hoist will show that the load rises rapidly at the beginning of a cycle and then drops off almost as fast to a little less than half the peakload. Here it remains practically constant until the cage or skip reaches the dumping point, when the curve drops down almost vertically. The filled-in outline of this characteristic curve resembles the silhouette of a chair, the top of the chair as the peak load and the seat as the constant load after the hoist has been fully accelerated. If possible, the load should be made more uniform so that the operating company would enjoy the reduced rate allowed by all power companies for operation under fairly constant load. The flywheel motor-generator set has another merit: there are no large losses in the starting rheostat.

The main shaft hoist is driven through single-reduction herringbone gears by an 850-hp. 350-r.p.m. 600-volt shunt-wound direct-current motor. The incoming alternating-current of 2,300 volts coming from the substation drives a slip-ring induction motor, which in turn drives a direct-current generator. On the same shaft is a flywheel and exciter. The motor is fitted with a slip-ring regulator so as to maintain full-load current on the motor at reduced speeds. The generator naturally supplies direct current for the operation of the hoist motor. The control is accomplished by varying the field strength of the exciting current.

The through shaft of the motor-generator set is mounted on four split pedestal bearings, one on either end of the set and the other two on either side of the 20,000-lb. flywheel. These bearings are lubricated both by gravity feed and oil rings. The flywheel bearings are further cooled by means of circulating water through the cored-out bearing shells. The water supply comes from a deep-well pump, from which comes also the water for drinking purposes and for cooling the slip regulator. This regulator serves also as a liquid rheostat for starting up the set.

Although the company has a power plant of its own, the transmission lines from it are in parallel with

FIG. 10

Hoist Room

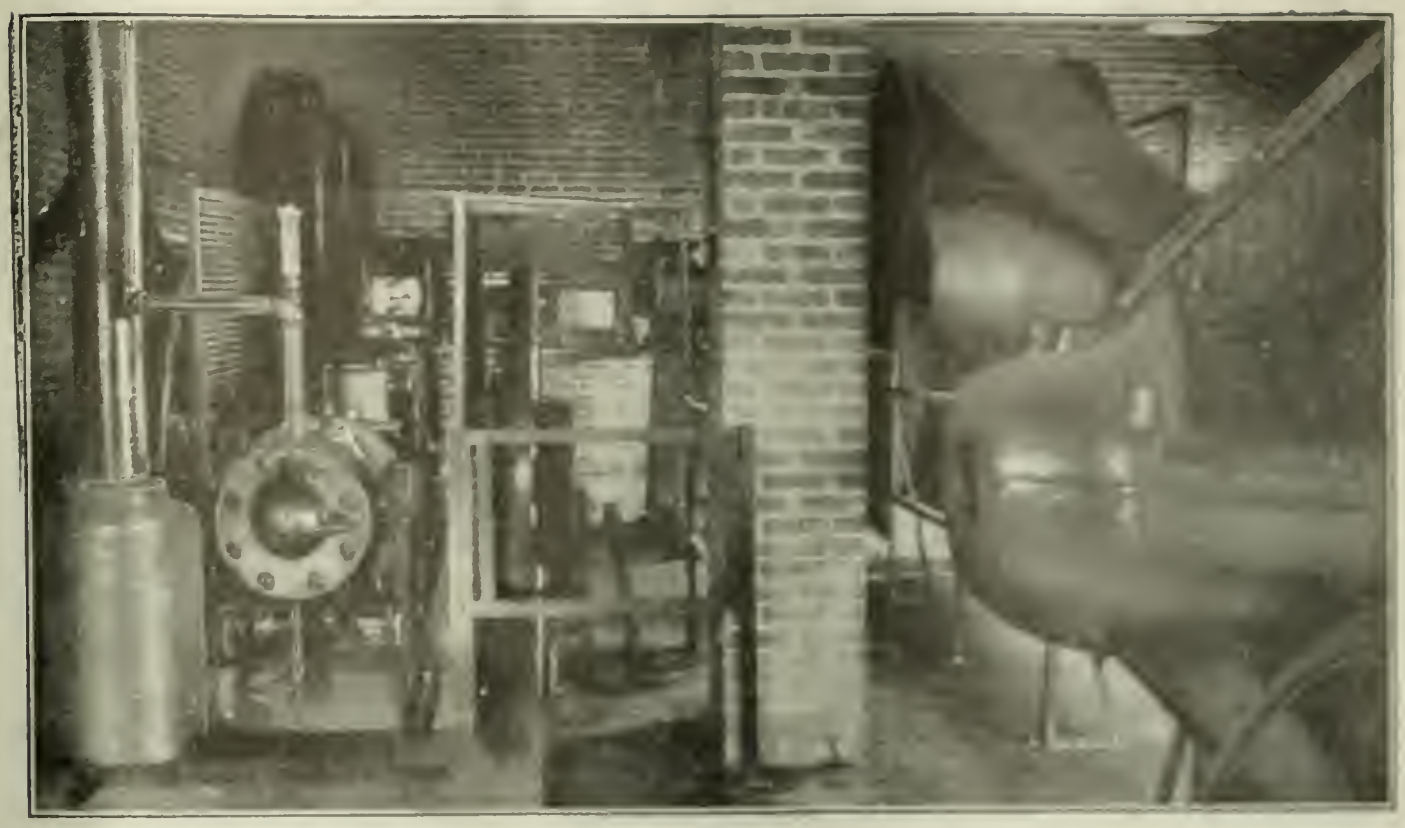

FIG. 11.

Fan House

The 5 x 12-ft. fan is driven by a 200-hp. induction motor. On the left is a fuel-oil engine as a standby in case the two sources of electric supply at this mine should fail. Every effort is made today to avoid the danger of an idle fan. The fuel-oil standby is independent of the company's steam and electrical power as well as of the power from the public-service station.

those of the Duquesne Light Co., to guarantee constant power supply. Thus the two sources of power may be drawn from separately or together. Though the risk of power failure is but slight the 200-hp. induction motor in the fan house is supplemented by an oil engine which stands abreast of the fan shaft, so that an almost instant change can be made in the fan drive by engaging a shaft clutch. C. M. Means, of Pittsburgh, Pa., was the consulting electrical engineer of this plant at the time of its construction.

American Coal Mining Institute Prepares To Answer Members' Knotty Problems

FIFTEEN questions, five papers, a banquet and a trip will occupy the time of the Coal Mining Institute of America during its winter session at Pittsburgh, Pa., Dec. 13, 14 and 15, the technical discussions taking place in the Chamber of Commerce Building and the banquet, in the dining hall at McCreery's store.

On Wednesday, Dec. 13, the meeting will hold its business session at 9 a.m., in which it will cast its vote on the new constitution. This meeting also will be addressed by Silas S. Riddle, chief of the Bureau of Rehabilitation of the Department of Labor and Industry, Harrisburg, Pa., on "Rehabilitation of Injured Mine Employees."

In the afternoon of Wednesday a question-box session, with W. E. Fohl, consulting engineer, as leader, will consider the following questions:

Question No. 1—What is the most important point to be considered when entering a mine after an explosion? (From Pittsburgh, Pa.)

Question No. 2—What are some of the practical remedies for the pollution of our streams by mine water? (From Clarksburg, W. Va.)

Question No. 3—What method should be used in working coal beds 30 ft. or more in thickness, as found in some of the Western states where the roof is only fair and the dip less than 5 deg.? (From Denver, Colo.)

Question No. 4—What electrical methods of shooting explosives in mines are to be preferred? (From Wilmington, Del.)

Question No. 5—What are the most practical methods of preserving mine timber? (From Pueblo, Colo.)

A paper will then be presented by Dr. Yandell Henderson, of Yale University, on "Methods of Resuscitation from Carbon-Monoxide Poisoning."

The annual banquet will be held at 6:30 p.m., at which the speakers will be Douglas Malloch, "The Poet of the Woods," Chicago, Ill.; Dr. E. A. Holbrook, dean of the School of Mines, Pennsylvania State University, and Jack Armour, the humorist from *Coal Age*.

The question box of the next morning will be opened by Jesse K. Johnston, general manager of mines, Bolivar, Pa., the questions being as follows:

Question No. 6—What is the most efficient method for humidifying mine air? (From Pueblo, Colo.)

Question No. 7—What is the solution for the overdevelopment of the bituminous coal industry? (From Philadelphia, Pa.)

Question No. 8—Which is the most efficient method for use in coal mines, hewed or sawed, and why? (From Johnstown, Pa.)

Question No. 9—Are doors necessary in the construction of a gaseous mine? (From Pittsburgh, Pa.)

Question No. 10—Would a national danger sign for use in all American coal mines be advantageous? (From Johnstown, Pa.)

At the close of this session David J. Price, engineer in charge of grain-dust explosion investigations, U. S. Department of Agriculture, Washington, D. C., will address the institute on "Industrial Dust Explosions and What Coal Men Can Learn from Them."

Thursday's afternoon session will be presided over by Alexander McCauch, state mine inspector, Mononghela, Pa., and A. C. Callen, dean of the School of Mines, West Virginia University, Morgantown, W. Va., will deliver an address on "Methods of Education in Coal Mining." These questions will then be discussed:

Question No. 11—Why should not all firemen and examiners [illegible] and be required to be men of [illegible] experience, be inspected and tested by the Pennsylvania inspection and rating bureau?

Question No. 12—At a drift or slope mine where the pitch runs from 7 to 8 deg. should a safety dump or a [illegible] be installed? (From Connellsville, Pa.)

Question No. 13—Can a wage [illegible] and based on the selling price per ton or bonus at the [illegible] operator and miner can agree? If not, why not? (From Pittsburgh, Pa.)

Question No. 14—Which is the better way to [illegible] coal, and why? (From Johnstown, Pa.)

Question No. 15—What is the most effective way of reducing the present appalling rate of accidents to mine [illegible] coal and rock? (From Connellsville, Pa.)

At the conclusion of this paper Bernard J. Reis, expert accountant, New York City, will discuss "Depletion, Depreciation and Other Factors Bearing on Cost."

On Friday a trip will be made by automobile to the power plant and mine of the West Penn Power Co. at Springdale, Pa.

What Hard-Coal Mines Are Doing to Lessen Derailments

Symposium Contributed by Six Leading Anthracite Officials as to Practice at Their Mines in Regard to Tire Repairs, Retracking, Track Revision, Bumper Guards and Other Details of Haulage Management

ASSEMBLED BY D. C. ASHMEAD*
Kingston, Pa.

"WHY are there as many derailments in coal mines? What are engineers and superintendents doing to remedy them? How are locomotive tires maintained?" These are questions agitating many mine executives today. Wrecks should be unusual happenings; instead they are of frequent, and in some mines of daily, occurrence. Three or four or more wrecks occur in some mines every day.

Consequently it was felt that a symposium of practices and experiences from engineers of the anthracite region would be interesting and useful. Several replies were received to a questionnaire regarding the subject. The first letter reveals the same difficulties in the anthracite region as have troubled the bituminous fields.

"Practically no derailments have been caused at our mines as a result of the lessening of the clearance due to the wearing of the tires. It is customary to keep locomotive tires in service till grooves from ¾ to 1 in. deep have been worn in them. Then they are turned. As far as I know, no accidents have occurred as a result of the grooving action. No tires have ever come off themselves during service, but on one or two occasions the wheels have become loose on the axles, but no wrecks resulted.

Bumper Guards Do Their Work Well

"All our locomotives are equipped with bumper guards, and no accident has arisen from the use of these devices. The switches and frogs of worked-out breasts usually are left in place till they are needed somewhere else.

"As for retrackers, we make them ourselves. They consist of V-shaped pieces of iron that can be laid over the top of the rail. They have a latch point riveted to the top of the V. In some cases factory-made retrackers are used. As a few points guard rails have been laid, but on none of our curves is the rail elevated or braced. In driving a new gangway, or tunnel, the first rails laid are regarded as constituting a permanent track. Sometimes it is lined up and properly ballasted later, but that is unusual.

"Too light a rail is used in the anthracite region. Much of our difficulty in regard to haulage can be traced to that fact. It causes numerous derailments, with consequent loss of time and loosened joints. This latter so joints makes it difficult to keep bonds in condition and is the cause of electrical trouble in the locomotive itself. The vibration and bumping which the light rail causes is injurious to the locomotive."

The electrical engineer of another company could not answer fully all the questions submitted. He replied, however: "Our locomotives are not equipped with tires. We use cast-iron wheels, and so do not have any trouble with tires that come loose. The wheels being of chilled iron, we do not turn them, of course. I would say that they have an average life of from five to six months. The groove on a worn wheel sometimes will cause an accident by catching in the frogs. As to the number of wrecks occasioned by loose wheels I have no information. We protect our locomotive motormen from cars jumping up and crushing them by the use on each end of the locomotive of a pair of the cast-steel bumper blocks."

A mechanical engineer of one of the largest independent anthracite companies says:

"There is a tendency to be careless in maintaining the haulage tracks of coal mines in good condition. Yet bad tracks in a mine are not only expensive; they are dangerous, and that is true of either animal or mechanical haulage. The mistakes made in the laying of mine tracks are four: (1) Light rails, (2) light ties spaced too far apart, (3) poor grading, with lack of ballast, and (4) absence of angle bars.

Half the Accidents Are Due to Bad Track

"Next to these as causes of haulage accidents comes carelessness in maintenance. Fifty per cent of the haulage accidents are chargeable to bad track. In many mines the track is repaired only after an accident, and then the mine foreman, looking for a cause, finds a worn, loose or broken wheel; usually it is the latter and is caused doubtless by the derailment, but the foreman in his report never blames the track.

"Fifty per cent of the locomotive repairs are traceable to the poor condition of the haulage roads. Guard rails are used at frogs but seldom on curves, where it is customary to elevate the outside rails. Rail benders should be used to make curves. The springing of rails to put a bend in the track is the cause of many derailments and accidents that could be avoided if a rail bender were used. When the rails are not permanently bent but are sprung into place they are held in line

BUMPER GUARD KEEPS CAR FROM INJURING DRIVER

The wheelbase being short in comparison to the length of the car and the change in grade sometimes sharp, it often happens that the bumper of the car tends to rise too high on that of the locomotive—to "lock bumpers," one might say, only that in this case the car does not merely pass its bumper over that of the locomotive but also crowds the locomotive driver against the coupler. To avoid this danger, bumper guards are used to keep the car bumper down to a safe level.

* Mechanical Engineer, Coal Age.

under stress, and a passing trip may readily loosen the spikes, with a consequent spreading of the rails and a derailment.

"Many curves in the mines could be greatly improved at little expense by trimming the rib. Make the curves of as long a radius as possible, and you will note a decrease in car repairs that will compensate you for the money expended.

"Accidents caused by loose wheels are few but when combined with those from spread rails will be found to form about 20 per cent of the haulage accidents. When mining is finished the frog and switch for that branch should be removed from the main haulage road, thereby reducing the possibility of a derailment. This is an item seldom overlooked by the foreman, who usually is waiting to transfer the switch to another branch.

"Worn locomotive tires rarely cause accidents but they do greatly increase locomotive repairs and also do much damage to frogs and switches. They should be turned after they have been worn down ¾ in. Mine-locomotive bumpers should be provided with top guards which should be of sufficient length to prevent the cars from 'climbing' and becoming derailed when being pushed over a summit, thus injuring the motorman by crowding him against the locomotive.

"Derailers of the saddle type and pressed-steel car-replacers are used to retrack derailed cars. Where a locomotive is available derailed loaded cars often are retracked by hitching the coupling to the top of the car and then pulling so as to retrack the hind wheels. The front wheels then are retracked with a short piece of rail placed between the locomotive bumper and the top of the car. This is placed a little out of center. By pushing on the rail the front end of the car is lifted and the front wheels are retracked at the same time. This is a practice which, though successful, frequently damages the car.

Cars May Be Hung Up on Guard Rail

"Guard rails should be protected with wedge-shaped iron or wood blocks to prevent the car couplings from catching the former. This provision increases the safety of employees and reduces equipment repairs.

"No track that is laid nearer to the face than 600 ft. should be of a permanent character or be so regarded, for if it is regarded as impermanent the engineers can establish grades and lay out a track that can be laid properly. Proper clearance spaces should be provided on both sides of haulage roads, and on passing branches room enough to insure safety should be left between cars.

"Ditches across haulage roads never should be left open. A pipe or pipes of sufficient capacity to take care of the drainage should be installed. Clean the roads thoroughly. Coal should not be allowed to accumulate along the tracks. Clean haulage roads not only increase the car yield but prevent accidents.

"Haulage roads should be carefully inspected and all loose roof properly supported or removed. Grade crossovers, heads of slopes, passing branches and all points where transportation men are required to couple and uncouple cars should be well lighted or given a coat of whitewash, preferably both."

An official of one of the largest anthracite companies writes as follows:

"All our locomotives are equipped with solid wheels, shrunk on the axle. The clearance height of the frame of the locomotive above the rail varies from 3½ to 4 in. Therefore there is no danger of the locomotive rubbing along the rail or the bottom.

"Our locomotives run on 25-lb. rails and the wheels are changed when about a ½-in. groove is worn in them. They are turned down about once. Our locomotives are not equipped with tires, no accidents having occurred from lack of this provision. I do not know of any instance where a loose wheel has caused an accident.

"Switches and frogs are removed from chamber branches as soon as there is no further use for them. This, of course, makes better main haulage roads and saves the switches and frogs from unnecessary wear.

"Our locomotives are equipped with two safety steel bumpers on the cab end at a height of 14 in. above the locomotive bumpers. The lug is 7½ in. above the bumper. The extension of the lug is 4 in. The width of the safety steel guard is 5 in., the thickness of the steel guard being ¼ in. This safety guard prevents a derailed car next to the locomotive, when being pushed or held back, from jumping up into the cab and injuring the motorman. If he uses ordinary care and obeys the company safety rules on speed limits, accidents from this cause should not occur.

Carry Retracker on All Locomotives

"Retrackers are carried on all locomotives. They serve to retrack satisfactorily both locomotives and cars. Jacks and car replacers are used only to retrack a derailed locomotive. When a replacer is carelessly held by hands or feet against the wheel, men are liable to be injured. Sometimes a prop or a tie is placed with one end against the locomotive bumper and the other against the top rail of the mine car for the purpose of lifting the car into place. In this method of retracking, men occasionally are injured. This unsafe method will swing the car to one side, and men have been caught between the car and the rib. Another way of replacing cars on the track is by a lever and blockings. This method also has its dangers.

"Guard rails are used on curves and at frogs. The rails are elevated on the long side of the track and braces are used on the curves when necessary. All rails used in development are taken out and replaced by a well-laid track.

"In only one instance in the last five years has a motorman been killed at our mines by a wreck caused by a runaway trip of cars and motor. This accident resulted from the carelessness of the motorman in charge. He pulled the trip over the summit onto a down grade so fast that the brakeman could not place the required sprags in the trip for its safe control.

"The following are some of the safety rules covering the operation of electric locomotives:

"Safety Rule No. 1—Every motorman must inspect his locomotive before taking it off the pit and he must report its condition on a motorman's inspection blank, giving the date and his signature and depositing the slip at the close of each day's work in a box kept for that purpose.

"Safety Rule No. 4—Motormen must insist that their brakemen and helpers put in sufficient sprags to show so that the locomotive and trip of cars are fully under control when running down grades.

"Safety Rule No. 5—Motormen at all times must carry car replacers, jacks and pinch of coal in their locomotives. Jacks and car replacers shall be used only to replace a derailed locomotive.

"Safety Rule No. 9—Motormen must not work their

locomotives if they do not have a good and efficient brake equipment with four brake shoes. Brakes must be in good working order at all times.

"Safety Rule No. 16—Motormen while pulling cars over main roads must not run their locomotives in excess of six miles per hour. When pushing cars the speed should not exceed three miles per hour. When approaching switches and going through doors the speed should not exceed two miles per hour.

"Safety Rule No. 23—Motormen, helpers and brakemen must not place a pin or prop against the bumper of the motor and the top sill of a car as a means of replacing cars on the track. Car replacers must be used and under no circumstances should cars be pushed by a pole.

"Safety Rule No. 24—Motormen, helpers and brakemen must not jump on the front end of a locomotive but must get on from the side. Riding on the front end is strictly forbidden."

The next letter is from another of the large coal companies: "In my opinion the causes of mine-train wrecks with their attendant delays in the day's schedule, their damage to equipment and their injuries to men, though many in number, are principally that the turnouts are too sharp, that lumps of coal or other refuse strew the track, that the rails are poorly aligned and that the tires have become excessively worn. The speed of these trains is such that the mishaps are not serious and usually only the cars are derailed.

"Some locomotives have a clearance as small as 2 in. and even that as the tires wear away would become less, but I have never been able to learn of an accident at our mines where this lack of clearance caused a derailment. It is the common practice to turn wheels as soon as they are worn enough to damage frogs, switches and crossovers seriously. A ½-in. groove is sufficient to cause much pounding on the track, but nevertheless the tires are more often worn about ¾ in. before they are turned.

"The tires on electric locomotives usually are turned after six to nine months of service and those on air locomotives are allowed to run without turning for a full year. A badly worn tire is apt to cause a derailment on a sharp curve or at a rail junction.

Practice to Use Tires Shrunk on the Wheel

"Locomotives rarely lose tires when they are shrunk on. If they should do so, I would ascribe their coming off to faulty installation. We have ceased to use demountable tires on our air locomotives because they worked loose, but no doubt a demountable tire of such design that it would remain tight on the wheel would prove most economical. Particularly is this true of the large six electrical locomotives.

"I have never known of a wreck being caused by a loose wheel, but of course that could happen from poor workmanship. An occasional inspection of the locomotive should reveal a defect of this sort to the motorman long before an accident occurred. In fact it is hard to see how he would fail to note it even without any careful inspection, so obvious would it be in operation.

"I understand that some locomotives have been equipped with anti-lifting hooks or similar devices to prevent the car next to the motor from being lifted from the track, but not all are so equipped. Almost all locomotives carry a steel retracking casting upon which to run derailed wheels and force them back on the track, using the power of the motor to pull them on the rails. However, should a locomotive entirely leave the track, jacks must be used to replace it on the rail. Levers are frequently used for the retracking of cars and in consequence men are sometimes injured by the falling of coal or the slipping of the lever.

"Guard rails are not extensively used, such as are laid being located at sharp turnouts on main roads and on planes, slopes and other places where their use is warranted. Braces are not used on curves, but the outer rails are elevated, and when a permanent road is laid it is graded and the rails are aligned."

The last letter will be one from an engineer with one of the larger companies who not long ago wrote an article on mine haulage:

"In the anthracite fields of Pennsylvania it is the general practice to keep the road between the rails clear down to the top of the ties. The only chance of rubbing would be from a lump of coal that might fall off the cars, but that would not be sufficient to lift the locomotive far enough from the rails to cause a wreck.

"Our general practice has been to use wheels having cast-iron centers with steel tires 1½ in. thick and wear them down as far as possible and then replace them with new ones, as it is sometimes impossible to turn them, so hard do they become by reason of the arcing from wheel to rail. They are worn down approximately ½ in. before they are removed from the centers. The groove is not allowed to become any deeper because a deep groove injures frogs and switches. When the wheels have grooves they are more liable to be derailed at frogs and switches than those having good treads.

Not Troubled with Loose Tires or Wheels

"As all our tires are shrunk on the wheel centers we have no trouble from loose tires. All cast-iron centers are keyseated and pressed on the axles, and in consequence we have no trouble from loose wheels, but we have had several wrecks from broken axles due to defects in the steel, and these have been overcome by using hammered steel axles instead of cold-rolled steel.

"Whenever the switches and frogs at the necks of breasts are likely to lie idle a long time before second mining will take place, they are removed so that the main line will be in good condition for haulage purposes.

"All locomotives are equipped with guards so as to prevent cars from jumping on top of the locomotive should the latter be derailed, and one general rule provides that when a locomotive is put into service it shall be so placed that the motorman will be at the end away from the loaded trip when coming out to the shaft.

"Each locomotive is equipped with a pair of standard retrackers and roadjack for use in case of derailment. Men are sometimes injured while holding the retrackers in place.

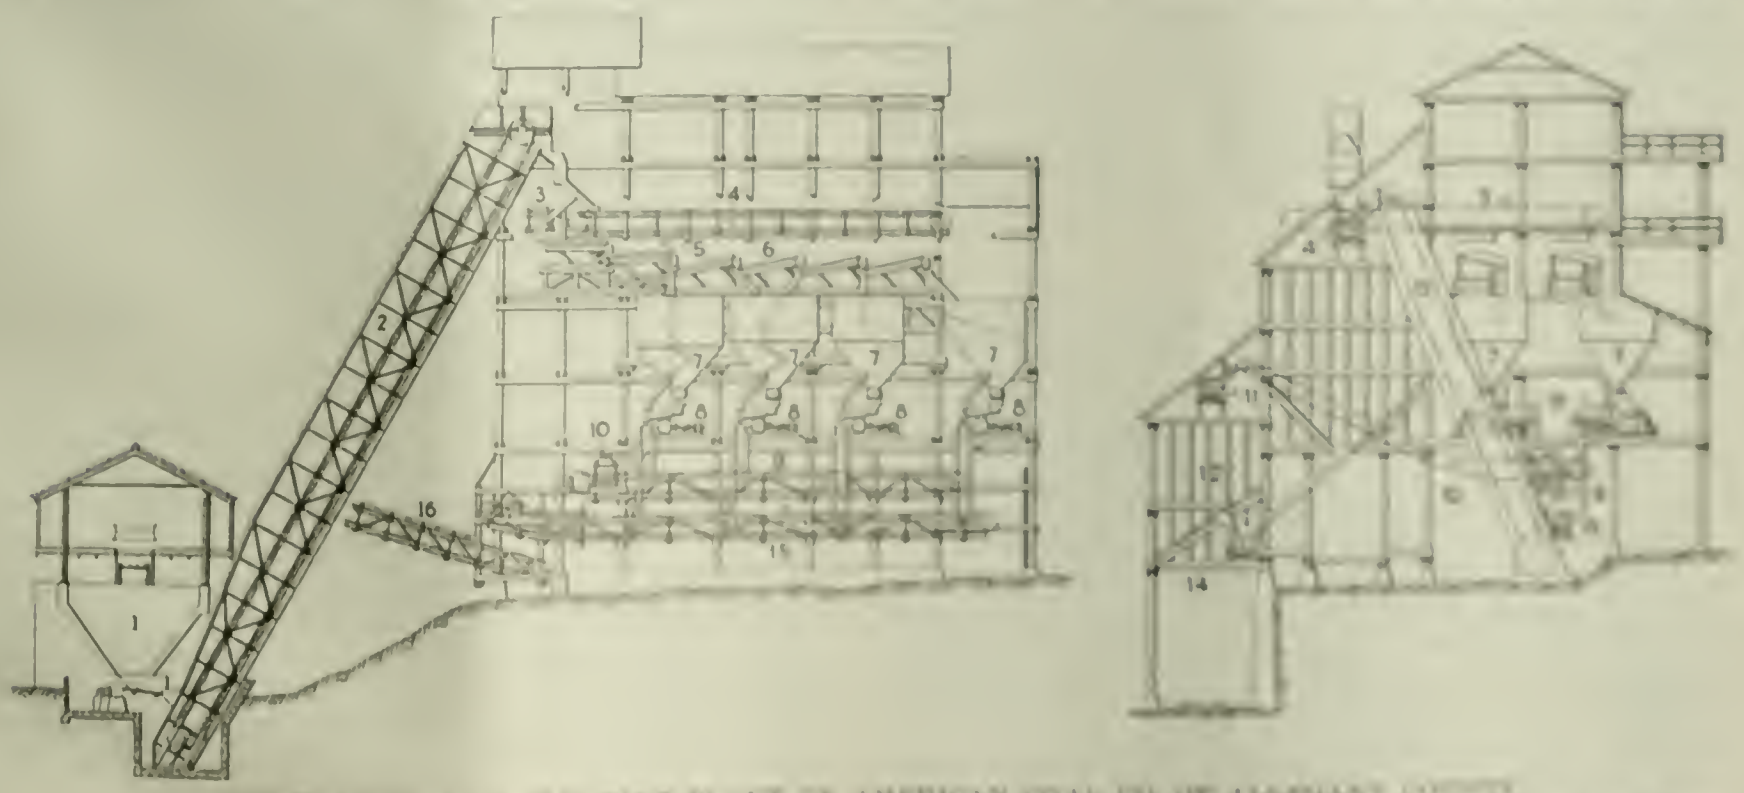
"Guard rails of wood and steel are frequently used on curves, and, as a rule, the rail is elevated to suit the radius of the curve, the rails being well braced at such places."

It will be seen from these six reports that practice varies from company to company. Probably there are no two companies in the anthracite region following the same rules in regard to the avoidance of derailments. Reference is frequently made in this symposium to loose wheels but always as to those on locomotives. The loosened wheel on the mine car is a far more frequent offender and should be, and doubtless is, given due attention by those who fail here to give it any verbal recognition.

Methods of Dry Cleaning and Dust Collecting at the Coal-Concentrating Plant of the American Coal Co.

Of Crane Creek Coal 60 per Cent Passes 2-In., 15 per Cent 1/16-In. Screen —1 x 2-In. Coal Has 22 per Cent Ash, Dust 10 per Cent—Screens Coal to Seven Sizes Before Tabling

AT THE Crane Creek Mine of the American Coal Co. of Allegany County, near McComas, W. Va., a large dry-process coal-cleaning plant is being erected. This will be the second commercial installation of this sort in this country, the first having been made for the St. Louis, Rocky Mountain & Pacific Co. at its Brilliant Mine, near Raton, N. M., this latter plant having just been put in operation with good results.



The American Coal Co. of Allegany County formerly operated a wet washery at which it treated all the coal from the Crane Creek Mine that would pass through a 2-in. screen. The results obtained by this method were never quite satisfactory for several reasons, the principal objection being that the coal was wet and in consequence froze and gave trouble during the winter months; that freight had to be paid on the moisture in the coal shipped despite the fact that it had, of course, no commercial value, and that the loss of coal in the process was excessive, particularly in the fine sizes. To these disadvantages should be added the ineffectiveness of the process in reducing the ash content of small sizes.

The coal mined at this property is from the No. 3 Pocahontas seam. This coal, as is well known, is soft and friable, and breaks up badly in mining. Of the mine-run 60 per cent will pass through a 2-in. perforation in the tipple screens, and of this small coal only 75 per cent is retained on a ½-in. perforation. The quantity of coal under 2 in. in diameter to be treated each hour is 240 tons.

At this Crane Creek plant instead of separating the non-combustible or refuse material from the pure coal by water, that separation is accomplished by means of air. The serious problems in successful wet washing, as almost everyone knows, are the recovery of the coal and refuse products from the water, the successful treatment of the finer sizes, the economical use of water and finally the drying of the washed product. All these problems are eliminated by the use of the dry, or air, method of cleaning.

Before erecting this plant the American Coal Co. of Allegany County made tests of their coal at the American Coal Cleaning Corporation's testing plant, located near Welch, W. Va. The tests were conducted over a period of several months and on a number of different samples.

The percentage of ash or non-combustible material in the uncleaned coal, or coal as received from the mine, varies greatly with the size. It will average 22 per cent on sizes which pass a 2-in. and are held on a 1-16-in. screen. The ash content of the dust, on the other hand, is only 10 per cent. The general average is about 16 per cent. After cleaning, the coal will contain about 5½ per cent ash. The refuse, or rejections, from the coal at the same time will average about 75 per cent ash. The refuse material is comparatively free

DRY-PROCESS COAL-CLEANING PLANT OF AMERICAN COAL CO. OF ALLEGANY COUNTY

(1) Bin in tipple for raw coal screenings, (2) conveyor delivering raw coal to screens, (3) flight conveyor depositing coal from elevator to the two sets of horizontal screens, (4) flight conveyor used as a bypass to distribute coal to the tipple bins or mine it is not to be cleaned, it also handles clean coal from [illegible] horizontal screens for first screening operation [illegible] perforations, (6) anti-gravity screens which [illegible] it up an incline; they have ½-in., ¼-in., 3-16-in. and 1-16-in. perforations, (7) hoppers of separated coal which [illegible] tables or pneumatic separators, (9) [illegible] conveyor, the upper run carries [illegible] coal [illegible] to the clean coal elevator, [illegible] for [illegible] coal and [illegible] for [illegible] coal, [illegible] coal [illegible] to [illegible] coal [illegible] to [illegible] coal screening bin, No. 1 and [illegible] to [illegible] coal screening bin, No. 2 and [illegible] to [illegible] coal screening bin, No. 3 and [illegible] to [illegible] coal screening bin, No. 4 and [illegible] to [illegible] coal screening bin, No.

[illegible] the coal and consists of rock, slate and a soft rash.

The plant installation as finally decided upon by the coal company will consist essentially of the following units arranged at different floor levels for convenience of operation. At the top of the building, or upper floor level, will be two batteries of sizing screens, each having a capacity of 120 tons per hour and producing the following sizes:

[illegible]

These screens will have not only a shaking motion but the screen decks will be vibrated as well, this latter action being accomplished by means of pneumatic vibrators. Each size of coal as produced will be conducted by chutes to bins in the structure below, which supply a steady feed of coal to the pneumatic separators.

The plant will contain eight of these arranged on a floor level immediately below the above-mentioned supply bins. Each of these machines will treat a single one of the above sizes except in the case of the two smaller sizes, for which two additional machines will be installed. It has been recently demonstrated by tests that the pneumatic separator will easily treat 25 tons an hour of the coarser coal and 12 to 14 tons per hour of the smallest sizes. It should be noted here that the coal finer than ¼ in. will not be treated in the American plant, arrangements having been made to mix this with the clean coal delivered from the separators.

How Coal Is Separated from Refuse

For the benefit of those readers who are unfamiliar with the pneumatic coal separator a brief description of the appliance is here given: On this machine, air—the weight of which is 1 [illegible] that of water—is used as the floating medium. The separation is made by taking advantage of the difference in the weight of materials. When mixtures containing particles differing in weight, such as coal and refuse, are fed to the deck of the machine, each product is separated by that difference in weight, and the separated material is propelled across the deck surface to suitable discharge spouts.

The table is hollow and airtight, except for the porous cover which distributes the air through the deck load and causes the partial suspension and stratification of the particles. The porosity of the deck and the quantity of air supplied are varied in the different tables to suit the size and kind of material treated. Deck covers are all of punched metal plate, the size and spacing of the holes governing the degree of porosity.

The tables for coarse coal are provided with ¼-in. galvanized iron ribbon riddel over a sheet of large-mesh [about ½-in.] wire screen, which in turn covers the punched plate. This screening adds to the retarding action of the riffles and prevents the back-slip of the deck load on the return stroke of the table.

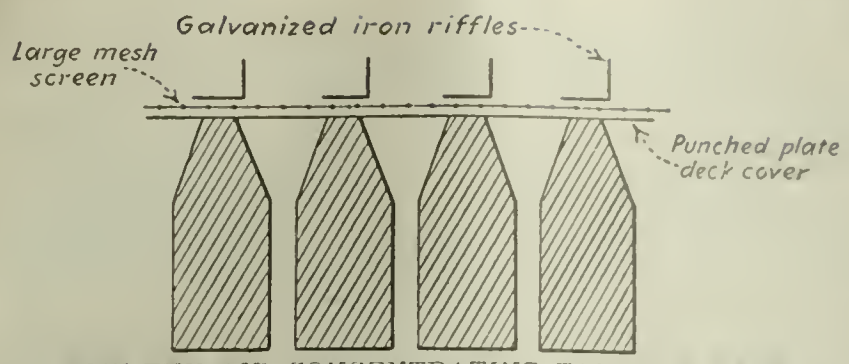
The action of the table on large sizes [over about ¼ in.] is improved by banking up the refuse by means of "banking bars" or baffles and keeping it on the table until it reaches the discharge edge. This banking causes a sharper line of demarcation between the refuse and the coal and also prevents pieces of coal from rolling on top of the refuse into the refuse compartment. This tendency is prevented also by a current of air through one of the banking bars which blows back into the coal zone coal that may be riding the refuse.

Inside the deck and supporting the cover are strips of wood immediately underneath the riffles and parallel to them. These strips assist in the distribution of the air and also furnish support for the perforated zinc cover.

Sometimes for the finer materials, strips of paper, called "retarding strips," are placed under the cover between the supporting strips. These retarding strips are wider at the fan end of the table and taper to a point at from one-half to two-thirds the distance to the concentrate end. They provide quiet zones between the riffles in which undersized particles of heavy material may be advanced into the concentrate when the feed is not accurately sized. These would be of advantage in coal cleaning for removing fine pyrite from the smaller sizes of feed.

Each Table Provided with Centrifugal Fan

Air baffles are provided within the deck to provide for the proper distribution of the air through the coal and refuse deck load.



Air for pneumatic separation is provided by a centrifugal fan built integral into the frame of the table. A flexible connection of heavy canvas joins the fan duct to the wind box, or deck, thus allowing for the motion of the table. A shutter over the intake of the fan adjusts the quantity of air which the deck receives.

The longitudinal and side slopes of the deck are adjustable, and both must be set accurately at the proper angles if the best results are to be obtained. The head motion of the table is a simple eccentric, the speed of the vibrations being adjustable through the medium of cone pulleys. The line of motion of the deck crosses the deck proper, due to the angular supports, so that as the deck advances in its stroke, it also lifts. On the return stroke of the eccentric the deck recedes and drops. This combination of motions advances the material toward the refuse end against the longitudinal slope while the lighter particles roll down the steeper transverse slope under partial suspension by the air.

The various adjustments of the table affect each other to a large extent, but there undoubtedly is a certain setting which for any size and any proportion of refuse will give the best results. The feeder also is adjustable so as to get the maximum tonnage over the table for various refuse percentages.

The pneumatic separators in the American plant will make three products, viz: clean coal and refuse and a middlings product that consists of an admixture of coal, refuse and boney coal. These products as they leave the separators are conducted by suitable spouts to conveyors below. The middlings product is conveyed to the elevator which delivers the raw or untreated coal to the sizing screens to which reference has been already made. In this way the middlings are mixed with the untreated coal coming to the plant and again find their way to the separators properly sized for treatment.

The final products made by the plant are only two, viz: clean coal and refuse. The various sizes of cleaned coal from the separators are combined and put into the shipping bins as nut, pea and slack, or any combination of these sizes. The refuse is conveyed to a bin in the tipple adjacent to the dry-cleaning plant, from which it is dumped together with mine rock and

HOW THE AIR CONCENTRATING TABLE IS MADE
Strips of wood are placed underneath and parallel to the riffles. Over these strips are quiet zones on which particles accumulate.

refuse picked from the picking table in the tipple. A further provision has been made in the plant for combining clean coal from the dry-cleaning plant with prepared sizes from the tipple, thus permitting the shipment of cleaned and picked mine-run or any other desired mixture.

An interesting feature of the plant is the means provided for collecting the dust produced by the operation of the various elevators and conveyors, the sizing screens and the pneumatic separators. (This dust-collecting system was furnished by the Clerk Dust Collecting Co., of Chicago.) Dust-collecting hoods are placed at all points where there is any possibility that dust will arise. These hoods are terminals of suitable pipes, which are connected in a continuous system to an exhaust fan and separating and collecting apparatus. The collected dust is delivered through a pipe to the conveyors which carry the slack size to the shipping bins, or it can be marketed separately as powdered fuel.

As will be noted in the illustration, the plant will consist essentially of three floor levels, viz.: the screening floor, the separator floor, and the lower floor, in the last of which will be placed the conveyors and the coal- and refuse-collecting equipment. The present wet-washing building will be remodeled to contain the new system. All equipment in the American plant will be electrically operated. Machines throughout will be direct-connected. In general the motors are of the slip-ring type and are controlled by push-button start and stop stations. The controls for the motors in the dry-cleaning plant are interlocked on the same principle as in the tipple, so that one motor in a group cannot be started in such a way as to cause material to be conveyed where it will block up the continuous flow. A master push button is provided that will start up the motors in a certain group in the correct order. All of the motors and the control equipment are of the Westinghouse type.

The dry-cleaning plant was designed and is being built by the Roberts & Schaefer Co., of Chicago. The screens and pneumatic separators are being manufactured by Sutton, Steele & Steele, Inc., of Dallas, Tex., under patents controlled by the American Coal Cleaning Corporation, of Welch, W. Va.

Trip Runs Wild on Slope, Cuts Conductor; Dust Ignites and Eighty-Six Die

EXCEPT in the number of dead the accident at Dolomite mine No. 3 of the Woodward Iron Co., Dolomite, Ala., that occurred in the afternoon of Nov. 22, is a double apparently of that at the Monongah mine of the Fairmont Coal Co. (now the Consolidation Coal Co.), in West Virginia. In that misfortune 361 men were killed. In both accidents a runaway trip apparently tore down an electric conductor and caused an explosion.

At the Dolomte plant the number killed was 86 and the number injured 59. Later reports may show that the loss is even greater than that stated owing to deaths of some of those now reported as injured. It appears that four cars had just been discharged on the revolving dump (which has capacity for five cars and is inclined on a slope of 15 deg.), when they broke loose, plunging headlong down the 30-deg. grade which leads 880 ft. into the mine, of which about 600 ft. is on the surface. It is easy to realize with what violence the trip reached the bottom. It must have been smashed to fragments. It appears likely that an electrical conductor of some kind—possibly a high-tension line—was torn down and that the short-circuit resulted in a conflagration of dust of such severity that flames are said to have shot up the slope several feet into the air and set fire to woodwork on the top of the tipple, reducing it to ashes. It is said that of all the men around the foot of the slope only one man still remains alive. In this section it seems that the concussion was severe but it is interesting to note a story that on some of the dead calcium carbide lamps were found to be still burning. All the foremen, of whom there were six, were killed.

A number of the victims succumbed to afterdamp. M. D. Wilson, who was seriously injured, relates that he succeeded in getting out by wrapping his woolen shirt about his head after dipping it in a bucket of water. This probably is a protection not against carbon monoxide but against the hydro-carbon constituents of afterdamp that have such a harmful effect. He asserts, however, that he supposes that this precaution kept his face from being burned.

At the time of the accident 475 men were in the mine. Of the 86 men killed, 21 were white and 65 were negroes. Three of the men were alive when removed from the mine but died later. According to the last report of the state mine inspector the mine generates gas, but sufficient fan ventilation and other safety provisions were maintained to cause the mine to be regarded as safe. Gas was not a factor in the explosion, for this slope is the main intake.

WHERE GAS FLICKS AWAY SOLDIER'S SHIRT AS SOFT
The cars at the time of their wild ride down the incline apparently dragged down an electric conductor which in turn was set on fire and exploded the dust of the workings. The dump and tipple at the top of the slope are from an inferior and unsatisfactory type of construction.

Labor's Opinion of Wages in the British Coal Industry

[illegible] by *Frank Hodges*, Secretary Miners' Federation

For the sixteen months since the investigation of the great inquiry the financial situation in the trade has been submitted to the owners and workmen by their joint accountants. Much more is known, therefore, within the trade about proceeds, wages, profits, and costs of production than ever before. From a study of the ascertained facts it is mutually admitted that the coal-mining industry is, and has been, passing through a period of adversity unparalleled in the annals of the trade. There have been unprecedented losses, both in wages and in profits. So much is this the case that the industry is on the verge of collapse. During the whole of this period the workmen and the owners have shared the common adversity in the proportions and in the manner laid down in the terms of the agreement of July, 1921.

The wages of the men have been reduced from the end of the "temporary period," i.e., September, 1921 (during which the government rendered the industry some assistance), by almost unbelievable amounts. This is best illustrated by taking the wage of a minimum wage coal getter in October, 1921, and comparing it with October, 1922. The reduction in the amount per day will give an idea of what the workmen have suffered.

	Wages per Day (Net)		Decrease Per Cent
	Oct. 1921	Oct. 1922	
	s. d.	s. d.	
	10 6	7 2	32
	9 3	8 3	12
	19 2	11 1	42
	14 6	8 7	39
	9 10	7 1	25
	14 3	10 4	27
	14 10	9 10	36
	17 1	9 11	42
	17 1	9 11	42
	16 10	9 8	42
	12 1	8 1	32
	16 10	11 6	42
	13 3	8 7	38
	19 10	11 9	39
	12 4	7 9	43
	15 7	9 0	42
	12 4	8 10	28
	15 7	9 8	42
	16 10	9 9	42
	17 1	10 1	42

The workmen are making a demand for a living wage or at least a wage comparable with the pre-war wage. How the present position compares with that in 1914 is shown in the following table. It sets out the average wage per man-shift worked in June, 1914, and for August, 1922, in the seven large districts in the country. The figures represent the estimates of the average wage of all classes of persons engaged in the mines, excluding the clerical staff, managerial and administrative salaries and wages. The increase above the 1914 nominal wage is shown both in money and as a percentage, whilst the decrease below the actual cost of living today is also shown as a percentage in the several districts.

	Average Daily Wage June, 1914		Average Daily Wage August, 1922		Increase Per Cent	Decrease Below Cost of Living Per Cent
	s.	d.	s.	d.		
	5	8	8	2	56	42 32
	2	11	5	1	81	47 43
	3	5	4	10	47	46 43
	3	11	5	6	41	57 55
	4	7	9	5	44	34 50
	4	11	8	4	80	49 51
	3	9	7	10	115	45 48

The average wage, therefore, is about 40 per cent above the 1914 wage. This wage is not being paid for the first time this month or last month. In South Wales, South Staffordshire and Kent, Cumberland, Forest of Dean, Newbury and Kent deep less no upward movement in wages since December, 1921. During the whole of this period the workmen in these areas have been living at a point far below the cost-of-living level. The public will understand that a great basic industry, such as coal mining, employing nearly a million of workmen and their families receiving an income 40 per cent and more below the standard of living.

The reason for this unhappy situation is that at the pit mouth the revenue from the proceeds of the sale of coal is not adequate to meet the cost of production at the pit. Cost of production should involve a living wage for the men and a reasonable return on capital for the owners. But the revenue has not provided even a poverty wage, whilst many collieries have gone out of production.

The miners do not desire a stoppage of work. They do not desire even to increase prices at the pit. But it is impossible to resist famine conditions much longer. The men are working up to the maximum of their physical ability. They are giving the country all the coal it requires. They have re-established the export market. The country cannot absorb all the coal which could be produced if employment were regular. All those things have been accomplished at the expense of profit, it is true, but principally through the sheer poverty of the men and the suffering of their families, who have endured it in the hope of a later recovery. This hope has been shattered.

Wages Paid Machine Miners, Runners and Helpers in West Virginia

THE FRENCH ARE TRYING out a new fuel composed of a mixture of alcohol and gasoline. We predict now it won't work. Experiments in this country have proved it is too dangerous.—*Philadelphia Inquirer.*

Problems of Operating Men

Edited by James T. Beard

Dead-Ending the Trolley Wire in Mines

Danger When Dead-End Is Carried too Close to Face of Heading—Keep Dead-End Fifty Yards Back—Improved Wire Splicers — Ohio Law Forbids Wire in Rooms

SOME time ago, I recall, the question was raised in *Coal Age* as to how near the dead-end of a trolley wire should be allowed to approach the face of a heading. (Vol. 17, p. 367.) An interesting discussion followed this inquiry. I believe the general opinion expressed was that the trolley wire should not be carried closer to the face of a heading than the last open crosscut.

For several years, I was in charge of work where trolley locomotives were in use. The mine generated no gas and I followed the practice of never permitting the trolley wire to be extended beyond the outby corner of the last crosscut.

Later, when in charge of a large mine where gathering locomotives were employed and the mine generated considerable gas, I made it a rule not to extend a trolley wire beyond the last room that had an open crosscut, on any entry. In making this the invariable rule in that mine, we took no chances on the ignition of gas through the breaking down of a trolley wire by a fall of roof.

No doubt some of the good readers of *Coal Age* will think that this was an unnecessary precaution; but we were keeping on the safe side, since falls of slate were of frequent occurrence between the last room having an open crosscut and the head of the entry. My fear was that such a fall might knock down the trolley wire and this, coming in contact with the rails, would produce fireworks that would ignite any gas present.

Plan Adopted to Avoid Frequent Splicing of Trolley Wire

Allow me, here, to describe what I consider a good scheme to adopt when driving entries from which rooms are being turned. The plan is to keep on hand two 50-yd. lengths of trolley wire. Then, as the face of the heading is advanced and the gathering locomotive approaches the limit of its reel in reaching the face, attach one of the 50-yd. lengths to the main trolley wire. This will enable the locomotive to proceed another 50 yd., as the heading continues to advance.

When the limit of the reel is again reached, attach the end of the second 50-yd. length to the first, which will permit of another 50-yd. advance of the heading. Now, when that point is reached, replace the two 50-yd. lengths with, say 100 yd. of trolley wire, splicing this permanently to the main wire.

Splicing the Trolley Wire

In attaching the two 50-yd. lengths when following out this plan, a form of trolley wire splicer similar to that shown in the accompanying figure should be used. The splicer shown in the figure is manufactured by the Ohio Brass Co., Mansfield, O. The bottom

IMPROVED FORM OF SPLICER

of the splicer is arranged to give an even run for the trolley wheel and avoid bumps.

On the left end of this splicer, the open lips are shown permitting the ready insertion of the trolley wire, after which these lips are pounded down and fit snugly against the wire, as shown on the right-hand end of the splicer.

In this type of splicer, the wires are held in position by steel chucks, serrated on the inside so as to give a strong grip to the wire. On the outside, these chucks are tapered to fit into a tapered hole in the splicer, into which they are driven after the wire is in place.

In another type of splicer furnished by the same company and adapted to a heavier tension on the wires, the latter are held in place by set screws. Either of these forms of splicer are easily adjusted and readily disconnected when desired.

Advantage of 500-Ft Extension

A considerable advantage will be gained, in the reduction of the number of permanent splices required in the main wire, if a 500-ft length of wire be used to replace the two 50-yd. lengths when the locomotive has reached its limit on the addition of the second length.

This 500-ft. extension of the trolley wire will not approach the face closer than 100 ft. and will enable the locomotive to operate (assuming a 500-ft reel) while the heading is being advanced 200 ft., when it will again be necessary to make use of one of the 50-yd. lengths and proceed as before.

In the previous discussion to which I have referred, mention was made of the Ohio law (Sec. 947) forbidding the extension of a trolley wire into a room that is being worked. I fail to see the practical application of this restriction in the Ohio law.

There are numerous instances, in mining practice, where rooms are worked in groups and, to avoid keeping up the roads in each room, switches are laid through the last inby crosscut and all the coal taken out through a central room of the group.

Saves Extra Trackage in Four Rooms

For instance, assume five rooms are being driven in a group. When these have reached the second crosscut, switches are laid in No.-3 room and cross-tracks extended to the right and left through the crosscuts, to enable all the coal from the five rooms to be taken out through No.-3 room. The scheme saves the extra trackage in four of these rooms. In such cases, I have known the trolley wire to be extended into No.-3 room; but this would not be permitted under the Ohio law. I hope to hear from others on this matter.

Some Points Relating to Use of Safety Lamps

Bent standards in a safety lamp a cause of glass breaking when lamp becomes heated—Careless methods of making tests for gas—Electric cap lamps should not be carried by firebosses

WHEN reading over the several letters that have been written regarding the testing and use of safety lamps, a few points suggest themselves that, I believe, have not been mentioned and yet have an important bearing on safe practice. It would be interesting to see these points further discussed, by the readers of *Coal Age*.

First, a matter of considerable importance, in the examination of a safety lamp to ascertain that it is in condition to be taken into a mine and exposed to gas, is to observe that the lamp standards are not bent or shortened, in any way, but are straight and of equal length.

This may seem an unimportant matter and scarcely worthy of attention, except as we reflect on the fact that any bending of the lamp standards will make some of them shorter than others and cause an undue strain to be thrown on the glass when the lamp becomes heated by exposure to gas.

[illegible] is true if the standards of a lamp are not all of the same height, which may occur as a defect in the manufacture of the lamp. On one occasion I saw a lamp glass break, owing to the standards having been slightly bent by rough usage in the mine. Fortunately, however, this occurred when the lamp was not exposed to an explosive mixture.

It is my belief that mine officials, as a rule, are not sufficiently particular in regard to the use and care of safety lamps by the men in their employ. Many officials seem heedless or, at least, lack a proper regard for the safe handling and inspection of safety lamps used in their mines.

How often do we observe assistant foremen and firebosses; yes, and foremen and superintendents also, for that matter, traveling about the mine and carrying a lamp having one side of the glass covered with soot. We must naturally conclude that if the glass is dirty the gauze is also dirty and the lamp for that reason unsafe. Yet there are hundreds of lamps used every day in that condition.

Examine Mines with Electric Cap Lamp on the Head

Another point has been suggested to my mind by a remark that W. H. Luxton made in his letter, *Coal Age*, Oct. 12, p. 594. Mr. Luxton stated, "Present-day practice, with a large number of our firebosses, is to carry an electric lamp in their cap."

Possibly, I am out of date in considering that any official whose duties require him to test for gas in the mine should carry no other lamp than an approved testing lamp. I am fully aware that many officials will claim that the extra lamp facilitates the examination of the roof. In my own experience, I have not found this to be the case. To my mind, it would be an imposition of old age and incapacity for the work, not to be able to see a crack if one exists in the roof.

With only the light of my Wolf safety lamp, I have run a surveyor's transit and read the verniers to single minutes with very little trouble. There can be no denying the fact that it is practically impossible to make an accurate test for gas with a safety lamp and, at the same time, have an electric lamp on one's head. If any one thinks it can be done, let him try it.

Making Accurate Test by Eyesight Is Difficult

In making this statement, I do not refer to testing a pocket of gas accumulated in a cavity of the roof or other like place. I mean that it is practically impossible to make the test in a return air current for determining low percentages of gas in the air traveling. This is more important than testing for isolated bodies of gas.

The only exception I would make, to my former statement, is that a man should carry a small flashlight when he has to examine falls, or other dangerous places. The flashlight will enable him to reach a place of safety in case he should lose the light in his safety lamp.

A testing lamp is a poor tool at the best, and my observations prove that when a man has a cap lamp along he gives less attention to his safety lamp, which often hangs at his belt, swinging and bumping at every step. If mine officials were taught to give the same care to their lamps as a soldier must give to his rifle, there would be fewer complained failures of standard testing lamps.

Using Steel Tamping Bars

Underestimating the danger—Accidents from this cause not common in Tennessee mines—Charging powder in paper cartridges — Practice when drilling with worn augers.

IN HIS ARTICLE, "Charging Holes With Steel-Headed Tamping Bars," *Coal Age*, Oct. 19, p. 637, my friend and neighbor, Oscar H. Jones, appears to be overexercised, in reference to the use of steel bars for tamping holes in blasting.

It appears that Mr. Jones regards this practice as having grown to a considerable extent in his district. He explains that the coal, in that locality, contains much sulphur in the form of balls and streaks, which is troublesome in drilling the holes for blasting.

When a drill strikes a sulphur ball, the latter being very hard, deflects the drill slightly. The result is that the hole is not straight and the sulphur ball is left exposed in the side of the hole, which our friend regards as very dangerous if a steel-headed bar is used to tamp the charge.

Danger of Striking Spark When Steel Bar Hits Sulphur Ball

Continuing, Mr. Jones claims that when such a hole is tamped with a steel-headed bar, there is every chance of the bar striking a spark when coming in contact with the sulphur ball. In that case, he considers an explosion of the charge almost inevitable and adds, "Such accidents are common in our mines, although they are wholly avoidable if proper precautions are taken and steel tamping bars prohibited."

While I do not wish to be understood as approving the use of steel tamping bars, it appears to me that the danger is not as great as Mr. Jones would have us believe. In other words, a premature explosion is not an inevitable result, though always a possible one.

Consider, for a moment, the method ordinarily followed by a miner when charging a hole. The powder is first placed in a cartridge made of strong blasting paper. After inserting the fuse, the miner either ties the mouth of the cartridge tight about it, or doubles the paper back and presses it down in a way to prevent the fuse from being pulled out easily.

This being done, the cartridge is pushed back gently to the bottom of the hole. No miner, having any regard for his own safety would push a cartridge back hard enough to strike a spark, by his bar coming in contact with the sulphur ball. But, suppose that did happen, the paper of the cartride would still intervene between the spark and the powder.

When tamping a hole with coal slack or clay, most miners make a short cartridge, 8 or 10 in. long, called a "dummy," or "dooly." This cartridge is filled with the tamping material and pushed back against the powder before any hard tamping is done. After the dummy is in place, no spark caused by the hard tamping of the charge could possibly reach the powder.

In respect to the material used in tamping a hole, I agree fully with my friend that clay or some other incombustible material should be used, especially if the charge consists of black powder. In my opinion, black powder should not be permitted to be used in many of our mines.

Use of Two Cartridge Pins When Bit Becomes Worn

In the same letter, Mr. Jones speaks of the auger bit becoming so worn that the hole drilled is too small to permit the cartridge to be pushed safely to the bottom of the hole. To say the least, I believe that any attempt to force a cartridge into a small hole would be reckless and particularly dangerous where the coal contains much hard sulphur, in the form of balls or streaks.

It is now several years since I have dug any coal; but, at that time, we kept two cartridge pins, a large pin and a smaller one for use should the auger become worn. This avoided the trouble and danger of bursting a cartridge.

Every miner, also, kept a scraper made of soft iron and having a small spoon at one end and a larger one at the other. These scrapers were used to clean the holes of dust and, at times, miners would use the big-spoon end to push some loose powder back into the hole. I have known a few reckless miners to get their cartridge fastened in the hole so that they could neither push it forward nor pull it back.

Should Not Tamp Holes Too Hard

In that case, the miner would generally tamp the hole and fire the shot. Frequently, the shot would pull its burden very well and no harm would result. However, I consider there is much risk in such a practice and believe it should not be allowed. Just here, let me say that many miners tamp their holes too hard—much harder than necessary. At times, you will hear the tamping bar ring as though it was striking hard coal. In my own practice, I have never tamped shots in that way and have always had good success in shooting.

Speaking of the common occurrence of accidents resulting from the use of steel bars in tamping, allow me to state that during the thirty-five years of my connection with mining in Tennessee, it

has not been my experience to see or hear of such an accident occurring in our mines. For four years, beginning June 1, 1910, I was district mine inspector, and my territory included the Wilder mine, where Mr. Jones is employed.

Every week I see and talk with the present inspector in that district. Yet, he has not mentioned such an accident as having occurred and I cannot think that accidents of that nature are frequent. It will be interesting to hear from others on this point.

JOHN ROSE,
Former District Mine Inspector.
Dayton, Tenn.

Industrial Peace via Golden Rule

Remedy for existing ills lies within reach of everyone—Practice of the Golden Rule the need of today.

WITH deep interest, I read the excellent letter of John Rose, which appeared in *Coal Age*, Nov. 2, p. 719, under the heading "Finding the Way to Industrial Peace." The remarks of Mr. Rose emphasized the present-day need of more religion in our industrial relations, one with another.

To say that I am in hearty accord with the sentiments expressed is putting it feebly. It is my belief that the practice of every-day religion is the only solution to the problems that now confront us on every hand.

It is not in coal mining alone that this need prevails, but in every industry throughout the length and breadth of the land. Operators and miners, employers of labor and workers in every trade and occupation must get together and co-operate if we are to secure the peace that is so much desired. Hard as the fact may be to realize, the remedy is within the reach of everyone. To my mind, no good results will be accomplished until we come to regard the work as beginning with ourselves.

WHERE RESPONSIBILITY RESTS

It is for the profiteering merchant who asks high prices for his goods; for the operator greedy for an unreasonable profit; for the capitalist demanding unreasonable returns on his investment; for the miner, day laborer, and other workers asking higher wages and making unfair demands respecting their labor—on all of these alike rests the responsibility of doing their share in the practice of the Golden Rule.

We might go on forever naming things that contribute to the high cost of living; but nothing will be accomplished that will be of benefit, until each one regards the problem as his own and is willing to do his share to make the world better.

This would be a wonderful world in which to live, if such a wave were to sweep the country and the chief endeavor of everyone was to treat another as he would be treated. There would then be an end to all industrial strife and prosperity would follow.

JAMES THOMPSON,
Mayport, Pa.

Inquiries Of General Interest

By-Products in the Manufacture of Coke

Numerous By-Products in the Manufacture of Coke—Skill and Knowledge Required to Insure Success—Principal Types of Ovens in Use

KINDLY permit me to ask for information, through the columns of *Coal Age*, regarding the by-products obtainable in the manufacture of coke. Also, does the bituminous coal used require to be of good quality, and does the recovery of these by-products require special skill and treatment?

Frontier, Wyo. INQUIRER.

The by-products recoverable in the manufacture of coke are numerous. Beside the coke dust and "breeze," there are the gaseous products, illuminating gas and fuel gas; and tar with its several distillates, consisting of the light volatile oils, naphtha and benzol, with their derivatives carbolic acid, creosote, etc.; followed by the heavier lubricating oils and the residue of pitch or asphalt and anthracene. There is beside the ammonia liquor, obtained in the washing and largely used in the manufacture of soap and allied industries.

All by-product processes require skill and a thorough chemical knowledge of the various hydrocarbon products that are formed, together with their use in the manufactures. Due regard must always be had, however, for the particular products it is desired to obtain. Some of the products named can only be obtained by the exclusion of others.

For example, the quality of illuminating gas, derived from the manufacture of coke, is much impaired if the benzol is taken out for fuel purposes. An expert knowledge of the chemical industries is therefore required to select and utilize these available products to the best advantage.

IMPORTANCE OF SAVING BY-PRODUCTS

The idea of saving the by-products in manufactures, generally, has received much attention in recent years and many industries are now based on the utilization of what was formerly a waste product of another industry. The study of the various by-products in the manufacture of coke has opened a wide field; and by-product furnaces or ovens have been specially designed for particular coals and requirements.

Chief among these is the type known as the "Semet-Solvay regenerative oven." In this type, the gas retorts or ovens are horizontal, while in another type of oven known as the "Koppers's oven," the retorts or flues are vertical. The successful operation of all types of by-product ovens is largely dependent on the uniform application of heat and a careful proportionment of the width of the furnace to the volume of gas generated.

Air Blasts and Bumps

Air blasts of a different nature from bumps—Former due to sudden rush of water accumulated on a pitch—Bumps caused by readjustment of rock masses within the earth.

READING the article entitled "Occurrence and Causes of Bumps in Coal Mines," *Coal Age*, Nov. 9, p. 760, has given rise to a discussion, here, as to the exact difference between an air blast and a bump, as these terms are used in coal mining. It would be interesting to have the nature of these two phenomena explained in *Coal Age*. I have contended that they are due to very different causes, but have been unable to explain in what way they differ. Apparently, each is manifested as a severe shock that often does much damage in the mine. STUDENT.

Nanaimo, B. C., Canada

An air blast, as the term is used in mining, is of a nature wholly different from what is termed a "bump." Air blasts only occur on steep pitching seams, or under conditions where a considerable body of water has accumu-

EFFECTIVE ACTION OF AIR BLAST

lated at some higher point and has suddenly been released and moved bodily to a lower point where it was brought to rest with a violent jar or shock.

An air blast occurring in a mine is of a nature quite similar to what is known as "water hammer" in a pipe system. In the accompanying figure we have attempted to illustrate one condition under which it is possible for an air blast to occur. In the figure as shown a fissure vein of coal, where

a heading has been driven beyond the fault, which is a downthrow.

A water header having been formed at the face of the heading (*F*), the pump was abandoned and a stopping put in (*H*), built to prevent the flooding of the mine. As the water accumulated in the space at (*HF*), it is evident that the rise of water level on reaching the roof at that point would entrap a considerable body of air at *S* and *E*.

As the water continues to accumulate, the pressure on the air at *S* is increased, being equal to the head of water rising toward the face. Nothing happens, however, until a possible fall of roof or coal agitates the water and the air and water tend to change places, the air forcing its way through the water, and the water rushing with great force against the dam. This is called an air blast.

The term "bump" has reference to a readjustment of equilibrium in the earth's strata. Owing to the unequal stresses set up through the extraction of the coal over large areas, or to one or more of the various hidden causes in the earth's crust, there comes a time when the formation is unable to support the strain thrown upon it and a readjustment takes place, which is manifested by a severe shock or jar that the miner term a "bump."

Examination Questions Answered

Miscellaneous Examination Questions

(*Answered by Request*)

QUESTION—*What are the minimum gradients, which should be given to underground roads for the following purposes: Water levels, levels for horse haulage, self-acting haulage, and direct haulage?*

ANSWER—In order to provide good drainage, the ditches, in a water-level entry, should be given a fall varying from 2 to 6 in. in 100 ft. For animal haulage on levels, the grade should favor the movement of the loaded cars. In order that it will require the same pull to move the loaded cars down a grade, as to pull the empties up the same grade, the road should be given a fall of from 1 to 1.5 per cent in favor of the loaded cars.

Self-acting inclines can be made to operate successfully on grades varying from 3 to 15 or 20 per cent, depending on conditions regarding the relative weights of the empty and loaded cars and the condition of track and rolling stock. It is not clear what is meant by "direct haulage." There are various kinds of rope haulage adapted to different grades varying from level to vertical.

QUESTION—*Give the comparative advantages and disadvantages of the longwall and room-and-pillar methods of working a coal mine.*

ANSWER—The chief advantages of the longwall method of mining are: Complete extraction of the coal; good ventilation at the working face; the avoiding of the necessity for building doors and stoppings; less expense for timber; and, finally, more direct route to the working faces.

Where the conditions are favorable longwall working has few, if any, disadvantages. The method requires the building of good packwalls, but this material would otherwise have to be hoisted to the surface, in many instances. A longwall mine can not lay idle for any length of time without serious damage to the work.

The room-and-pillar method of mining has the advantage of providing separate working places for the men, where each man is responsible for the condition of his own place. This method gives a smaller production of coal in the first working, a large percentage being left as pillars for the support of the roof, until the work of robbing is commenced. The room-and-pillar method affords opportunity for a squeeze or creep to develop and much coal is often lost in pillars that can not be recovered.

QUESTION—*What must be carefully considered before the work of drawing pillars is begun?*

ANSWER—Before drawing pillars the possibility of future development must be considered carefully; and the effect that the taking out of the pillars will have on adjoining workings and on the surface. The work must be so arranged that the line of pillar work will be more or less straight, so that no excessive pressure will be thrown on any of the pillars. The question of the presence of water or gas in the overlying strata, must be determined, and provision made to avoid accident on this account.

QUESTION—(*a*) *What are your reasons for or against systematic timbering and should it be adopted?* (*b*) *Can the road and working places be kept more secure than when the timber is staggered and set up irregularly without system as to space and alignment?*

ANSWER—(*a*) The chief advantage of systematic timbering lies in the fact that the miner is not permitted to follow his own judgment and can not postpone the setting of timbers, as he would do, otherwise. The roof pressure is more uniformly distributed in systematic timbering and less timber is crushed by excessive weight than where the posts are set irregularly. There is less danger, also, from a hidden slip in the roof being undiscovered and causing accident. On the other hand, systematic timbering requires a larger outlay for timber than may be necessary, at times. Under uniform roof conditions, systematic timbering is advisable.

(*b*) Roads and working places are always more secure where systematic timbering is employed.

QUESTION—*When is an electric wire said to be grounded?*

ANSWER—An electric wire is said to be grounded when it is in connection with the ground, or with a system of pipes running into the ground, in such a manner that the current will pass from the wire into the ground.

QUESTION—*If a breast is driven a distance of 500 ft. on a rising grade of 10 per cent, what should be the distance represented on the map of the mine, and what height has the breast attained above the gangway level?*

ANSWER—In this case, the pitch distance is 500 ft. and, the grade being 10 per cent, the grade angle or angle of inclination is that whose tangent is 0.1, or 5° 43′. Then, since the cosine of this angle is 0.995, the horizontal distance corresponding to the length of the breast is $500 \times 0.995 = 497.5$ ft., or 4.975 in. as measured on the map.

The total rise of the breast above the gangway is 49.75 ft. In this calculation the percentage of grade is estimated on the horizontal distance, which is common practice in seams of moderate inclination.

QUESTION—*In a non-gaseous mine hitherto worked with open lights, marsh gas has made its appearance in considerable quantity. What lamp would you recommend to be used by the workmen?*

ANSWER—Under these conditions the workmen should be equipped with electric cap lamps, or provided with locked safety lamps of an approved type.

QUESTION—*What first-aid treatment would you give to a workman whose eye has been injured?*

ANSWER—Remove at once any speck of coal or other foreign matter observed on the eye. If the injury is severe, while waiting for the doctor apply absorbent cotton or soft cloth soaked in cool water, bandaging the same, not too tightly, but sufficiently so to prevent movement of the eyelid. Keep the cloth and bandage constantly wet with cool water to prevent inflammation. A few drops of olive oil in the eye will help to allay irritation. Never allow the injured one to rub his eye.

CORRECTION

Examination Question, Nov. 9, p. 762—Last lines of the answer to the first question on the page should read: Finally the velocity of the air current is 80,000 ÷ 64 = 1,250 ft. per min.

Domestic Coal Situation, as Shown by the Government Report on Consumers' Stocks as of Oct. 1*

By W. F. McKenney, E. E. Finn and F. G. Tryon

As time progresses it becomes clear that if there is to be any pinch in the coal market this winter it will be in the supply of domestic fuel. Further, it is clear that if any region experiences difficulty it will be the anthracite-consuming territory of the Northeast. Finally, it is clear that the success of any community in meeting the pinch, if one develops, will be proportionate to its foresight in substituting other fuels—bituminous coal, coke, oil or the smaller sizes of anthracite—for domestic anthracite.

The Geological Survey has made no forecast of the condition of the coal market next winter because forecasting is not consistent with the Survey's regular business of reporting on the facts of supply and demand. Observers outside the government seem to agree that the country ought to be able to pass the winter with no crisis in the supply of steam coal. Anxiety is still expressed in some quarters over the low reserves of household anthracite, but it is generally agreed that by substituting other fuels, the stringency can be met.

It is pointed out that the responsibility for educating the public to the need of substitution and for providing the substitute fuels themselves rests largely with the retail dealer. The real test of his success in meeting the situation, it is agreed, will come with cold weather, when the current consumption of anthracite passes the current production. It is recalled that the consumption of anthracite is vastly greater in January than in October, perhaps four times as great. There can be no doubt of the ability of the bituminous industry to supply substitute fuel, if given time enough. The danger, if any, lies in delaying the demand for the substitute until too late to provide it at reasonable cost and with reasonable promptness.

Because the supply of domestic fuel will assume such unique importance, it has seemed worth while to restate in greater detail the figures on the retail coal situation which were summarized in the recent report on stocks of coal undertaken jointly by the Bureau of the Census and the U. S. Geological Survey under authority of the Federal Fuel Distributor. The figures represent deliveries during the month of September and the condition of stocks on Oct. 1. At this date they are matters of history, but it is a history out of which the events of today have sprung and without which the developments of to-morrow cannot be understood. It must be remembered that these figures represent a sample only, and a rather small sample at that, probably only 20 per cent of the total tonnage handled by retailers. It is, however, a typical sample.

Stocks Outside the Anthracite-Consuming Territory

In discussing the present situation it is necessary to differentiate sharply between territory north and east of the line of the Missouri, Ohio and Potomac rivers, on the one hand, and the territory to the south and west of that line on the other. The first includes all the states where anthracite is a significant element in the domestic fuel supply (Fig. 3), although even in many of these states, notably Iowa, Illinois, Indiana, Ohio and western Pennsylvania, subordinate to bituminous coal.

Outside the anthracite-burning zone practically the entire population cooks its meals and warms its dwellings with soft coal, and there the question of the supply of domestic fuel becomes simply, "How does the condition of retail yards compare with normal at this season?" From the accompanying tables and diagrams it will be seen that stocks on Oct. 1 were low, but that dealers had been endeavoring to make up for the delay during the strike by delivering coal at a faster rate than normal.

First, as to stocks on hand Oct. 1, Table I shows the tonnage in the yards of a selected list of retailers outside the anthracite zone. In comparison with a year ago (Nov. 1, 1921) they showed a decrease almost everywhere (column 6 of Table I and also Fig. 1). On the average the decrease was 67 per cent. But, of course, 1921 was a period of comfortable stocks. In comparison with a time of shortage—such as June 1, 1920—the 1922 stocks outside the anthracite zone showed an increase (last column of Table I). In making this last comparison, however, it must be remembered that they ought to show a large increase, because retail stocks are generally higher in the autumn than in the summer.

Next, as to demand and the rate that retailers were supplying it. The sample retailers outside the anthracite zone, shown in Table I, delivered more coal to their customers in September, 1922, than in the preceding September. From Fig. 2 it will be seen that this increase was general, though not universal, in the non-anthracite territory. It was a natural increase to make up for unavoidable postponement of usual deliveries while the strike was on.

Stocks in the Anthracite-Consuming Territory

Inside the anthracite zone conditions were much less favorable.

Stocks of Anthracite.—Stocks of anthracite itself were very low on Oct. 1. The quantity in the cellars of householders, concerning which no statistics are available, was undoubtedly but a fraction of normal. Stocks in the yards of retailers (anthracite only) were the lowest on record during the period over which statistics extend. The figures given in the government's report need not be repeated here, but in brief they showed that retail yards carried only 13 per cent as much on Oct. 1, 1922, as at the corresponding time last year. At the rate of delivery made by these dealers to their customers in September, 1921, the stocks on Oct. 1, 1922, were sufficient for 7 days.

Anthracite in Massachusetts.—These reports to the Federal Government from a selected list of retailers are confirmed by the records of the Massachusetts Fuel Administrator, which cover all yards in that state. Massachusetts dealers had 73,000 tons of anthracite on Oct. 1, 1922, only 8 per cent of what they carried a year ago, and even barely a third of what they reported on Nov. 1, 1920, at which time a temporary scarcity existed. The anthracite stocks

reported to the Massachusetts Administrator have been as follows, in net tons:

[illegible]	[illegible]	[illegible]	695,000
[illegible]	[illegible]	[illegible]	727,000
[illegible]	[illegible]	[illegible]	535,000
[illegible]	[illegible]	[illegible]	146,000
[illegible]	[illegible]	[illegible]	47,000
[illegible]	[illegible]	[illegible]	73,000

Anthracite and Bituminous Combined—To speak of anthracite stocks alone, however, means little, for it neglects the efforts of many dealers and consumers to stock up with substitute fuels. Yet even considering anthracite and bituminous as a common source of supply the reserve on Oct. 1 in the anthracite zone was far below normal. Table II shows that, as compared with Nov. 1, 1921, stocks of all coal showed a drop of 66.7 per cent and that even compared with the low point of June, 1920, they showed a decrease of 11.8 per cent. The same story is told graphically by Fig. 1. Not a state in the anthracite zone but exhibits a decrease from November last year even in *all* coal in yards, whether hard or soft, and in many states the decrease was as much as 75 per cent.

Substitutes of Bituminous—Announcement that anthracite will be distributed on the basis of 60 per cent of last year's shipments brings home the fact that consumers must find substitutes for the remainder of their requirements. The reports indicate that during the month of September there was some replacement of anthracite with bituminous coal, but they also show that the replacement had not gone far enough to make up for the deficit in the supply of anthracite.

The extent of the replacement is indicated in Table III. A group of 125 dealers in New England delivered 139,000 more tons of bituminous coal in September this year than last, but delivered 210,000 less tons of anthracite. As a result their total deliveries of all coal were 71,000 tons less this September than last, a decrease of 17 per cent.

(*a*) Includes only dealers from whom reports were available for each of the dates. The dealers reporting include only a fraction of the total.
(*b*) A plus sign denotes an increase; a minus sign, a decrease.

What was true in New England was true of New York, New Jersey and the Lake dock states: deliveries of bituminous increased, but not enough to make up for the decrease in anthracite. In other words, after a five months' strike, retailers were delivering to their customers less coal rather than more than usual.

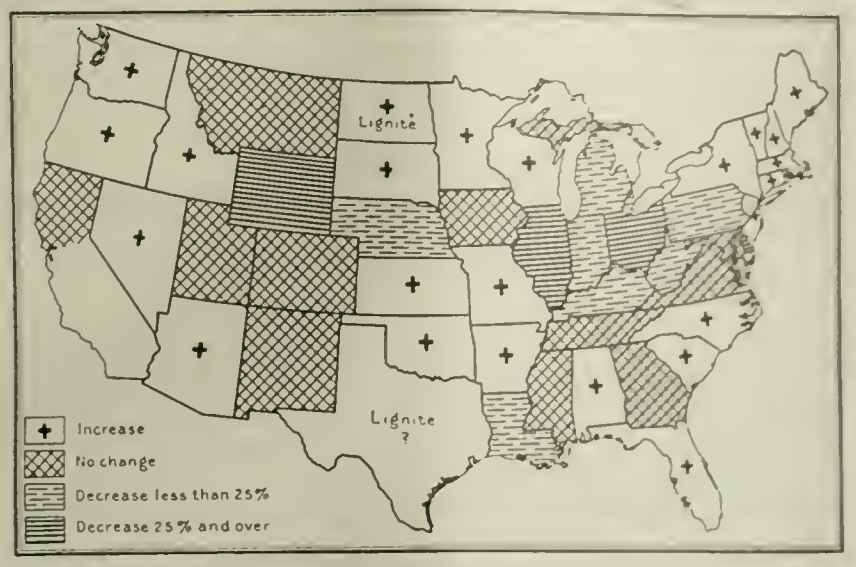

FIG. 2—HOW RETAILERS' DELIVERIES OF BITUMINOUS COAL IN SEPTEMBER, 1922, COMPARED WITH THOSE IN SEPTEMBER, 1921

Deliveries of bituminous coal to domestic consumers were nearly 10 per cent larger in September, 1922, than in the corresponding month a year ago. The map shows that deliveries generally increased or were at least as large as last year, except in the coal-producing states east of the Mississippi and north of Tennessee. The most notable increase occurred in the New England states, where deliveries were 93 per cent larger than during last September.

FIG. 3—HOW RETAILERS' DELIVERIES IN ANTHRACITE-CONSUMING TERRITORY OF ALL COAL IN SEPTEMBER, 1922, COMPARED WITH THOSE IN SEPTEMBER, 1921

As a result of the 23-week anthracite miners' strike, retailers' deliveries of anthracite during September, 1922, were but 24 per cent of the September (1921) deliveries. Deliveries of bituminous coal to domestic consumers in region did not suffice to equal the decrease in anthracite. The map shows that in the anthracite-consuming territory, with the single exception of Rhode Island, less coal was delivered by retailers in September, 1922, than in the same month a year ago.

Still more anomalous was the condition in the other states of the anthracite zone—Illinois, Indiana, Ohio, Pennsylvania and the lower peninsula of Michigan. In these states deliveries of bituminous coal itself, to say nothing of anthracite, were smaller this September than last (Fig. 2). Presumably this was due to a wholesome tendency of the shippers of these states—all coal producing to take care of long-haul destinations first—but it indicates how large a task remained before the retailer after Oct. 1 if his customers were to receive their usual supply.

Deliveries of Anthracite and Bituminous Combined.—The total quantity of all coal, hard and soft, delivered in September, 1922, showed a decrease in every state of the anthracite zone with one exception—Rhode Island (Fig. 3).

Responsibility of Retailer for Substitution.—The foregoing statistics show that the retailers of the anthracite zone, as of Oct. 1, had inherited a serious responsibility. Direction by federal boards and bureaus could do little to lighten the retailers' task. So delicate a thing as readjustment of the consuming habits of millions of householders could be accomplished only by local adjustments made by local dealers. It is a task to capitalize all the skill and restraint of the American retail coal merchant. It is up to him individually to diagnose his local market, advise his customers, forecast the demand for substitutes, and start them moving through his yard before congestion occurs. It is clear that some districts, New England for example, and Rhode Island in particular, had shown much more enterprise than others during the period covered by the stock report. The extent to which other communities have since followed this lead will largely determine the adequacy of their household supply in the winter.

The task of the retailer has been lightened by the unusually mild autumn. The average temperature in November has been decidedly above normal in the anthracite zone, just as November, 1918, was above normal, and November, 1919, below. If the weather man has not boosted the coal man's profits this time, he has at least spared him some undeserved criticism.

Supply of Byproduct Coke.—After the anthracite strike of 1902 many householders got through the winter by buying coke. Continuation of the late strike in the Connellsville region is curtailing the supply of beehive coke which would otherwise be available, but the byproduct ovens are producing heavily. The output of byproduct coke in October was 2,806,000 tons, a figure greater than the monthly average for even 1920. Of this quantity a considerable tonnage is available for domestic use.

Active demand for household fuel has largely absorbed the heavy stocks of unsold coke which had accumulated at byproduct coke works last spring. Statements courteously furnished by 19 byproduct coke operators supplying gas to the municipalities under contract show a decrease of 72 per cent from March 1 to Oct. 1, 1922. As the stocks of surplus coke at such plants on March 1 were slightly over 1,000,000 tons, it appears that the October stocks were about 270,000 tons.

In the Northeast the accumulation of unsold coke had been almost completely liquidated by Oct. 1. A considerable surplus remained, however, in certain cities of the West and Northwest.

Navy Lets Coal Contracts Till Jan. 1; to Ask New Bids for Rest of Fiscal Year

Announcement was made Nov. 22 that the Navy had accepted the bids submitted by the Iron Trade Products Co. of Pittsburgh, for November and December coal requirements at Higham, Mass.; Navy Yard, New York; supply depot, Brooklyn; Lake Denmark, N. J.; Washington Navy Yard, Bellevue Magazine, District of Columbia; Alexandria and Annapolis, calling for approximately 22,000 tons of coal.

No provision was made for the Navy at Philadelphia, it being explained that the successful bidder did not have sufficient tonnage to fill these demands as well as the others.

The acceptance of the short-term bids means that the Navy Department will call for new tenders to be submitted during December, the exact date to be announced later, calling for the delivery of more than 100,000 tons of run-of-mine coal. The reasons given for the failure of the Navy to accept the proposals for the long term were that the price was considered too high for the quality of coal sought and it was believed that more advantageous arrangements could be made later.

There were eleven sets of bids submitted on Nov. 14, but the Iron Trade Products Co. was the only firm to bid on the entire demand.

Following are the awards made, the prices being for delivered coal:

Higham, Mass., 240 tons, $6.35 and $6.45.

Navy Yard, Brooklyn, 4,000 tons, $6.71, $7.37, $7.37, $7.13, $6.74 and $6.74.

South Brooklyn, N. Y., 2,000 tons, $6.71, $7.37, $7.13, $6.74, $7.38 and $6.80.

Long Island, N. Y., 300 tons, Dunn Gr. $6.22, Pr. $5.98, $6.37, $6.00, $5.88, $6.32, $6.00, $7.07 and $7.38.

Lake Denmark, 400 tons, $6.15, $7.45 and $7.75.

Washington Navy Yard, 4,200 tons, $6.35 and $6.45.

Naval Torpedo Station, Alexandria, 370 tons, $6.30, $6.35 and $6.44.

Annapolis, 10,000 tons, $7.09 and $7.37.

President Would Amend Coal Commission Act to Make Questionnaires Answerable Under Oath

By Paul Wooton
Washington Correspondent of *Coal Age*

President Harding has requested Senator Borah and Representative Winslow to suggest an amendment to the coal commission act which will make questionnaires answerable under oath and which will provide penalties for false statements or failure to reply to questionnaires. The act provides that the commission may issue subpoenas and may demand the presentation of books and records. This process would be cumbersome and it is believed that the situation can be met better under the amendment proposed.

Most of the preliminary work incident to organization and to the threshing out of policies has been accomplished. The commission is now getting into the fundamentals of its work. It is true that no brass tacks have been uncovered as yet but the objectives have been decided upon and the whole organization has started on its march toward them.

In some quarters an impression seems to have been gained that the commission is going to recommend what it considers a just and reasonable wage scale. Apparently the commission has no idea of acting as arbitrator in a wage dispute. Its function is one of fact finding, which differs radically from one of arbitration. It would be manifestly impossible for the commission to undertake to prescribe reasonable wage scales, which vary in each district. That would necessitate a study of the situation in a large number of individual mines. The thought that the commission might undertake some such function may be partly responsible for the polite skepticism of the replies received from the operators and from the mine workers and for the appeal which they made to the galleries.

Doubt Pervades Coal Industry

The coal industry appears to be very much in doubt as to what to expect from the commission. Marshall, Howell, Alschuler and Devine are four names which have been heard infrequently among those engaged in the coal trade. The industry has no preconceived estimate of the ability of those men to pass upon matters which concern them. On the other hand, the industry has a definite appraisal of Hammond, Smith and Neill. It never has thought of Mr. Hammond in connection with coal, but his ability in all matters pertaining to mining is well understood. Dr. Smith is the veteran head of a bureau which has taken a distinctly friendly attitude toward the industry and which does work of high quality. Mr. Neill is recognized as one who has had remarkable success in the arbitration of labor disputes and whose knowledge of employer-employee relationships is profound and constructive.

The public and the industry expect a report that will mark a distinct advance and which will display all the properties of good workmanship. Moreover, the public expects concrete results promptly. Not only does the law specify that there is to be a preliminary report on Jan. 15 but the public generally realizes that if the real purpose of the commission is attained its findings will be needed more as a guide during the next few months than may be the case during years that follow. The commission is functioning during an emergency. The industry needs it though as the work progresses. Most commission reports are leisurely reduced to writing. Proofs are read and re-read. Finally they are made public when the Superintendent of Documents has an ample supply for general distribution. Were the coal commission to follow this procedure, it would miss its main opportunity.

The staff of the President's coal commission at present is made up as follows: C. E. Lesher, engineer in charge of the engineering studies of the production, transportation and distribution of coal; David L. Wing, accountant in charge of obtaining production costs; Prof. Joseph H. Willits, in charge of the study of wages, earnings and wage contracts. Mr. Lesher will be assisted by R. A. Walters, of Reading, Pa., and by C. A. Allen, of Salt Lake City. Mr. Wing is being assisted by H. S. Piers and James E. Black, who have been transferred for the purpose from the Federal Trade Commission. Miss Anne Bezanson, of Philadelphia, who formerly was in charge of a special study on wage earners for the Harvard committee on economic research and who now is connected with the industrial research department of the University of Pennsylvania, will assist Professor Willits.

Under the direction of Commissioner Neill, Miss Marie L. Obenauer will make a survey of living conditions and the cost of living in mining communities. She will be assisted by Miss Frances Valentine.

Commissioners Neill and Alschuler have been assigned the supervision of the investigation relating to labor facts. Commissioners Marshall and Devine will supervise investigations dealing with economic facts while Commissioners Smith and Howell have been assigned the supervision of the studies of engineering facts. In addition, Chairman Hammond will give much personal attention to the engineering phases of the investigation.

Miss Obenauer to Study Living Conditions Among Miners for Coal Commission

Miss Marie Obenauer, widely known as a result of the many industrial surveys which she has made during the past fifteen years, has been retained by the President's coal commission to assist Charles P. Neill in his study of living conditions in coal-mine communities. Miss Obenauer com-

Miss Marie Obenauer

piled an important position with the War Labor Board in which examiners for the employers and for the employees submitted their reports on wages in industry to be for analysis prior to their presentation to the Board. In that capacity she represented neither the employer nor the employee group.

Miss Obenauer came to national notice prior to the creation of the Department of Labor. In the old Department of Commerce and Labor she had charge of the women's division. At that time the department represented the public. When the Department of Labor was created, its organic act provided specifically that it represent labor. Miss Obenauer

[illegible] the government action soon after the division of the department.

Just before the United States entered the war Miss Obenauer undertook a survey conducted jointly by the National League for Women's Service and the federal government to ascertain the number of skilled operatives who could be recruited among women to serve in factories engaged in the manufacture of war supplies.

Miners Will Not Submit to Wage Cut Next Year, Says Searles

Prospects for peace or strikes in the coal-mining industry next year was the topic of an address by Ellis Searles, editor of the United Mine Workers' Journal, before the Business Science Club of Philadelphia at a luncheon at the Hotel Adelphia, in Philadelphia, Nov. 24. Mr. Searles said, in part:

"Whether there will be another strike of coal miners next year is a question that no living man can answer today. But I can say that the miners will not submit to any reduction in their wages, nor will they permit the coal operators to take away from them any of the conditions of their employment which they have won by many years of struggle, hardship and sacrifice. If there are any in this country who are anticipating lower wages for coal miners next year they may as well abandon that anticipation now and devote their spare time to some other subject. The miners are not asking for any general or universal increase in their wages in the bituminous industry, but miners in the anthracite region have asked, they are now asking and they will continue to demand increased wages until their wage rates are brought to the level where they belong and where justice to the mine worker and his family require that they shall be placed.

"For many, many years there has been a wide disparity between the wages of anthracite miners and those in the bituminous industry and in comparison with the wages of men employed in other comparable industries and lines of work. Wages of anthracite mine workers always have been too low and they must be brought up to a decent American level. Next year will see miners of the anthracite region contending as valiantly and heroically for an improved wage scale as they have done heretofore, and they will continue so to contend until they obtain what is justly due them. And they will not abandon their striving for the universal eight-hour day in the anthracite industry. Eight hours is the uniform length of the work day in every soft-coal field of this country, except in those places where the miners are positively denied their constitutional and legal right to organize or to join a labor union. In the anthracite industry, however, men labor eight, ten, twelve or more hours every day in order to earn a living for their families. Such a system is inhuman and unjust and it must give way to the progress that has marked all industry in America in recent years.

"Eight hours is long enough for any man to labor in or around a coal mine. If any of you doubt the truth of that statement, just go out and try it. You will find it is hard labor. More than that, it is work in which there is a greater degree of danger to life, limb and health than in almost any other profitable industry in which men are engaged. Consider the fact that in the anthracite region of Pennsylvania alone there are 500 to 600 deaths each year of men employed in and around the mines, and there are 20,000 injured each year in preventible accidents. This is a frightful toll for men to pay for the privilege of producing coal for the use of us. And we who enjoy the benefits and the comforts that flow from the labor of these men ought to be honest and fair enough to grant them a measure of compensation that will justify them in taking the awful risks that are encountered in the mining of coal. And in the bituminous industry the situation is practically the same. Government statistics show that more than 2,000 men are killed each year in and around bituminous mines and that tens of thousands are injured. The hazard of the coal-mining industry is so great that I am told the insurance companies insure coal miners only if they pay a rate six [illegible] years above their actual age."

Spangler Deaths Laid to Use of Open Lights When Gas Was Known To Be Present

A jury summoned by Coroner M. W. Swabb to hear the evidence and place the blame for the explosion in Reilly mine No. 1, at Spangler, Cambria County, Pa., on Nov. 6, when seventy-seven lives were lost, placed the blame for the explosion on the owners and management of the mine. After an all-day session on Nov. 21 the jury reported on Nov. 22 that: "With the knowledge of the company there was an insufficient number of firebosses employed, that open lights were used in the presence of dangerous gas and that the ventilation in the mine was inadequate."

District Attorney D. P. Weimer of Cambria County attended the inquest but has not decided upon a course of action. A fair summary of the vast amount of evidence submitted to the jury and put into the records would indicate that accumulations of gas were frequent in the Reilly Colliery, that the men who lost their lives and the men who escaped had general knowledge of conditions, that the mine foremen and firebosses knew of this condition and that the officials were kept busy patching up places where there was danger. Foreman Flanagan, in his testimony, asserted that while he knew of the existence of gas and took many precautions at various times to dispel accumulations, he did not consider the mine dangerous to work in. He did believe it was a difficult mine to work in, that general physical conditions were hard, but he did not agree with a number of witnesses that the mine was actually a dangerous place in which to work.

Seward E. Button, chief of the state mining department, in his report submitted to the Coroner's jury, recommends that the Reilly mine be worked exclusively with approved safety lamps. He also recommended that permissable powder be used for blasting, all shotholes to be tamped the full length of the hole with incombustible material, and all shots be fired with electric detonators by shotfirers, coal cutting machines to be of the approved closed type, also that a sufficient number of firebosses be employed to examine a mine thoroughly before each shift.

Spens Revokes Daily Report Requirement

Regulations requiring bituminous-coal operators to furnish the Federal Fuel Distributor with daily statements as to coal loadings, prices obtained for coal, and destinations to which coal is shipped were revoked Nov. 24 by Fuel Distributor C. E. Spens, effective Dec. 1. These regulations, which were promulgated on Sept. 27 and 28 and Oct. 4, required that daily reports of coal shipments in the territory east of the Mississippi River be transmitted to the fifteen naval officers acting as district representatives of the Federal Fuel Distributor. Operators in trans-Mississippi territory were required to make their reports directly to the Federal Fuel Distributor, except that Iowa, Montana and North Dakota operators reported to C. P. White, Assistant Federal Fuel Distributor, at St. Paul, Minn.

Anthracite Tax Adjudged Constitutional

Washington, D. C., Nov. 27.—The Supreme Court of the United States today affirmed the decision of the Pennsylvania Supreme Court holding the Pennsylvania anthracite tax constitutional. The highest court held that there is a difference between anthracite and bituminous coal since anthracite is used only as a fuel whereas bituminous coal is the base of byproducts. Nine states using 80 per cent of the anthracite produced in Pennsylvania intervened in the case, declaring that this will increase the cost of coal to them. The court, however, held that there was no cause for complaint on the part of these states since the tax was levied before the coal is offered to a common carrier, whereupon it would be subject to national legislation.

High Price of Anthracite Attributed to Inflated Wages Demanded by Mine Workers*

When anyone connected with the producers of anthracite is asked to talk about "economic and business aspects" of the coal industry it does not require a great deal of imagination on his part to know that what his auditors want is an answer to the question: "Why do I have to pay so much for coal?"

The public has a deep-seated conviction that the price of anthracite is too high. This belief is the real basis for the public demand for fact finding about coal that led to the passage of the law creating the U. S. Coal Commission. And the main fact that the public expects the commission to find, so far as anthracite is concerned, is that the public can and should get its domesite fuel supply at a lower price. Assuming, as we may, that this able commission will deal only with facts these are some of the things that it will necessarily find:

First, that anthracite production is different in every essential respect from bituminous coal production. There is no overproduction of anthracite, there is no irregularity of production except that occasioned by the acts of the workers and, in spite of the public conviction to the contrary, the industry as a whole makes no excessive profits.

The production of anthracite is a costly and elaborate underground engineering proposition, and after the coal is brought to the surface from depths of from 500 to 1,500 feet it is cleaned, washed and sized in huge breakers which cost today about $1,500,000. Without going into the technical details of anthracite production, let me mention a few facts which indicate why it costs so much to produce hard coal.

For every ton of coal produced 11 tons of water must be pumped out of the workings. Besides the necessity for ridding the mines of some 800,000,000 gallons of water a day, an operation requiring continuous pumping 365 days a year, it is necessary to hoist and dispose of about half a ton of rock and dirt for every ton of coal produced. Every minute of every day two tons of air are forced into the anthracite mines for ventilation. The timbering of the mines requires the use of 500,000,000 board feet of timber every year, or about 7 ft. for every ton of coal produced.

That anthracite mining is in reality a manufacturing proposition is shown by the fact that of the 150,000 men employed in the industry only about 42,000 are directly engaged in mining. The other 108,000 are employed in the handling and preparation of the coal for market.

These operations give a different picture from the conception of coal mining which imagines it to be merely the scooping out of easily accessible supplies and the loading of the coal on the cars for market.

But all of this, you will say, does not justify the price of $14 a ton for anthracite coal. It does not. But it is only a part of the story. In the first place the anthracite producer does not get $14 a ton, directly or indirectly. The coal for which the New York consumer pays $14 or more is sold at the mine at the present time for about $8.25. But don't imagine all of the coal is sold at this price. About one-third of it is the so-called steam sizes, which the mine owner is compelled to sell below the cost of production. In 1921-22 the average realization on the whole production was not more than $6.28 a gross ton.

Let us look into the items that make up the mine price of anthracite. Labor costs $4.11; $1.05 goes for supplies; 58c. for administration, making a total of $5.74. Subtract this from the amount realized on the whole production, $6.28, and there is 54c. left, representing the average margin between production cost and mine price. Out of this margin must come trade discounts and taxes, which reduced the average profit of the anthracite operator in the past two years to not more than 35 or 40c. a ton. In other words, if all of the profits made by all of the anthracite producers in 1921 and 1922 were eliminated, the price of coal could have been reduced by about 40c. a ton.

The labor cost in this computation, which has back of it the authority of S. D. Warriner, based on a most careful investigation, was stated at $4.11. But obviously coal selling for $2 a ton, which is the average price of the steam sizes, constituting about 30 per cent of the commercial production, could not carry a labor cost of $4. In other words, the larger domestic sizes must carry more than the average labor cost. According to Mr. Warriner's computation, a fair allocation of the labor cost would make this item $5.20 per ton in the case of stove coal.

It is going to be fairly easy to convince the coal commission or for the commission to convince itself that the mine price of anthracite on the basis of present labor and other costs is fair, and that it cannot be reduced until these costs are reduced.

But what about the difference between the mine price of $8.25 for the domestic sizes and the price the consumer pays? This is made up of freight, which in the case of New York is about $2.75 per ton, including lighterage, and the costs and profits of retail distribution. The anthracite producer has nothing to do with his product, and derives no profit from it after it leaves the mine. Except for some legal details in the case of one or two companies, anthracite mining and railroad transportation are divorced industries, and whatever profit is made out of the transportation of anthracite goes to the railroad.

Operators Not Responsible for High Freight Rates

If railroad freight rates are too high, if dealers and distributors are adding too much to the mine price for their services, it is something for those interests to account for. The producer can only tell you what he gets for his product at the mine, what it costs him to produce it and the profit he makes out of it. There are some properties exceptionally favorably situated which realize more than the average profit I have stated, but there are many that average less and there are others that make no profit at all. These facts, however unpalatable and however different from the ideas commonly prevailing, are nevertheless facts which the searching investigation of the fuel commission may be expected to confirm.

Even the briefest discussion of economic aspects of the anthracite industry cannot ignore the labor problem, especially in view of the fact that it is labor disturbance that has centered public attention upon the industry in recent months. The labor cost of producing anthracite, according to the U. S. Bureau of Labor Statistics, has increased more than 118 per cent since 1914. Notwithstanding the fact that mine wages alone, among those paid by basic industries, have been increased instead of diminished since the end of the war, the miners presented to the anthracite operators early this year demands which would give them a further increase of wages, and add about $1 a ton to the cost of producing domestic anthracite.

There has never been a break for twenty years in the relations between anthracite producers and organized labor. There was no refusal this year on the part of the anthracite operators to negotiate with the miners' representatives. In fact we were committed in such negotiations and expected to proceed with them when, at the first meeting of the negotiators in March, we had presented to us a notice of suspension of mining on April 1. Protests against the unreasonableness and unwisdom of this step were brushed aside and an anthracite strike was initiated which lasted for five months—possibly one of the most costly and at the same time most useless strikes that this country has ever had—and at the end of it the miners went back to work at their old wages.

The basic rate of pay in the anthracite industry is 53c. an hour for common labor, all other wages grading up from

*Abstract of address by Daniel T. Pierce, of the General Policies Committee of Anthracite Operators, at the meeting Monday evening, Nov. 27, at Town Hall, New York, under the joint auspices of the Women's City Club and the City Club of New York. Other speakers were Senator William E. Borah, of Idaho; Arthur H. Learoyd, of the New York State Fuel Administration, and Thomas Kennedy, vice president of the United Mine Workers.

the figure at least which make the anthracite miner the aristocrat of the world's workers. You may recall that a month or so ago a great deal of attention was centered upon the fact that the Steel Corporation had increased wages 20 per cent, but with this increase the common labor rate in the steel industry was raised to only 50c. an hour, while the anthracite industry pays 85c. Every other class of workers has accepted reductions from war-time wage peaks. Every other worker, therefore, is paying out of declining wages the inflated wages of anthracite workers. By reason of the fact, as stated by President Harding, that the people of the United States are at the mercy of the United Mine Workers the mine workers have been able up to this time to resist any adjustment of their wages corresponding to the adjustments that have taken place in all other industries. Having done this, the miner is not very much impressed by the statement of economists that it could not be done. But as soon as urgent necessities are satisfied, the miner will find that he is going to pay dearly for his victory in the form of interrupted employment which will reduce his earnings, whatever his wage rate may be.

The cost of labor alone is now more than the average selling price of anthracite at the mine before the war. The miner insists upon judging his wage, or the labor cost of anthracite, with relation to the retail price, whereas it can reasonably be judged solely with relation to the mine price.

These are a few of the economic aspects of the anthracite coal problem. Every producer of anthracite will agree that the retail price is too high. He wishes that it could be lower because he is fearful that consumption will be reduced by the high price, and he has not even the consolation of high immediate profits to compensate for this danger. He has an investment of about $8 per ton of annual production in a hazardous industry. A 10 per cent return, which he ought to get on such an investment, would give him 80c. a ton. On the average he gets about half that. Nevertheless he bears on all sides that he is a gouger.

Pittston Miners Threaten to Strike Unless Superintendents Are Changed

Operators committees of two locals of the United Mine Workers of America whose membership is employed at collieries of the Pennsylvania Coal Co. from Dunmore to Pittston, Pa., have voted to call a strike of the 10,000 workers at these collieries on Dec. 1 unless the company by that time accedes to the committee's demand to transfer 13 superintendents at the collieries in question.

This action came after a stormy session of four hours at which Rinaldo Capellini played a leading rôle. The meeting was called to adjust a dispute that came from the Old Forge local, No. 1256, whose members had a one-day strike the forepart of last week as a result of the transfer of Mine Foreman William Campbell from the Old Forge colliery to the Butler colliery and the sending of Arthur Young to the Old Forge colliery. The Old Forge grievance committee alleges that one of the first acts of the new foreman was to discharge two members of the grievance committee.

Illinois Receptive to Almost Any Wage Plan That Can Get U. S. Approval

Illinois has more or less made up its mind on the outstanding question: "What of future wage negotiations with the miners' union?" On Nov. 21 in Chicago, the operators of the state crystallized their opinion for the benefit of Van Horne and W. K. Kavanaugh, their representatives on the joint conference of operators and miners which tried to talk for four days beginning Nov. 14 to agree upon some method of future wage negotiations and which reconvenes Dec. 6 in New York. The Illinois view is, first, that the operators of the country certainly should meet the miners before April 1 in an effort to stave off another strike; second, that negotiations preferably should be by districts or by single states but that, as a second choice, the old Central Competitive Field or some similar group of states should get for the operators after hearing the contentions of the outlying district men, points that the Federal Coal Commission ought to be invited to observe the negotiations whenever they take place; fourth, that in case of disagreement with the miners, arbitration be offered as a last effort to avoid closing the mines, and fifth, that governmental sanction be obtained before any agreement is made. These ideas were put in the form of a resolution as a guide to Messrs. Miller and Kavanaugh.

The Illinois meeting was the fulfillment of an agreement made at the joint conference two weeks ago that the operators at that conference, having failed to unite upon any plan for negotiating the next wage scale, would all go home and talk it over with their constituents. The results of the Illinois meeting are to be carried by Messrs. Miller and Kavanaugh first into a session on Dec. 4 of the operators' half of the joint conference and then into the full conference of Dec. 6 when the operators may have united upon some negotiation plan. Up to the present there has been no unity. Outlying fields strove for, and were refused, a voice in national wage making and there was not even harmony among the four original states of the Central Competitive Field on the question of renewing the old four-state plan of wage making.

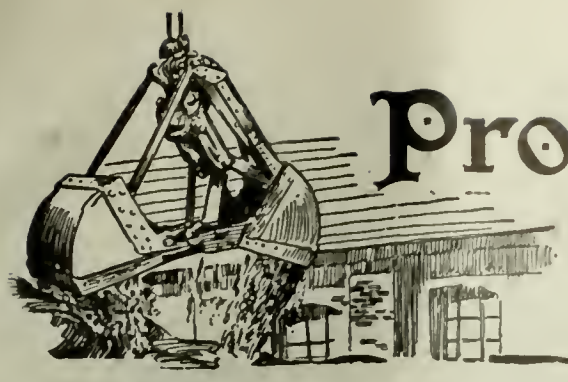
The attitude of Illinois is that strong effort be made to avoid a strike but that the operators of the country should do absolutely nothing that would lay them once more liable to indictment on a charge of conspiring with miners to set a wage scale for the country that would elevate the cost of coal to the people.

Attitude of Commerce Commission Turning Against Assigned Car Practice

Such a good showing has been made by the witnesses opposing the practice of assigning cars for railroad fuel that it is apparent that the attitude of some of the Interstate Commerce Commission members is changing. During the opening hearings it was apparent that the commission was disinclined to take any action that would add materially to the expenses of the carriers. The evidence as to the disruptive influence of the assigned car has been so conclusive, however, that none will be surprised if the commission should rule that assigned cars are to be used only during a real emergency and even then the permission of the commission may be required.

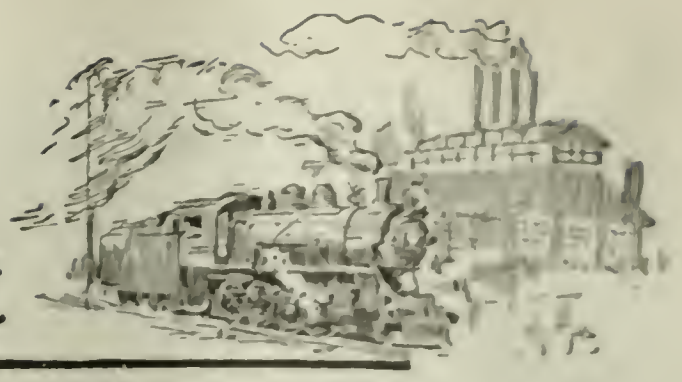
A large number of operators have presented figures showing their actual losses as a result of inequitable car distribution. Others testified as to how they have been forced to take railroad contracts at unprofitable figures so as to keep their mines in operation. B. E. Neal, president of the Neal Coal Co., of Indianapolis, was among the most effective witnesses presented by the operators. His earnestness and his fund of concrete information clearly impressed those sitting in the case.

Much credit is due to John Brophy, who spoke for the United Mine Workers. He declared that unequal running time as between mines is inequitable to labor and causes much dissatisfaction.



The defense of the railroads has been much weaker than was expected. Their attorneys have not made a good showing. That the railroads recognize the trend against the practice is evidenced by the fact that they have made drastic reductions in the number of assigned cars used since the hearing began.

Several operators who specialize in railroad contracts appeared in support of the assigned-car practice.



Retailers Submit Proposals to Commission

The National Retail Coal Merchants' Association has submitted a statement to the President's Coal Commission presenting the attitude of the association on the investigation which the commission is undertaking, dealing in detail with both the anthracite and the bituminous situation. Specific recommendations are made to the commission for bettering the situation with regard to each fuel.

ALFRED M. OGLE, president of the National Coal Association, who was stricken with appendicitis last week, is well on the road to recovery.

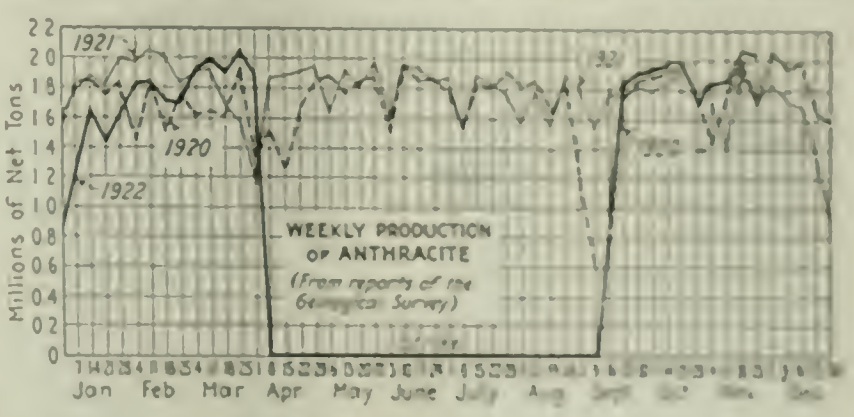
Production and the Market

Weekly Review

The spot coal market is quiet. Buying is confined to current needs, even in the domestic branch, and the tendency to acquire seasonable reserves has not passed beyond the stage of making inquiries on prices. *Coal Age* Index of spot bituminous coal prices receded to 330 on Nov. 27, as compared with 343 on the preceding Monday. The average price at the mine corresponding to this index number is $3.99; last week it was $4.16.

The market can be divided into two sections today. In the territory served by the regions producing coal for the Lakes there is absolute stagnation. Buyers are marking time while the Lake shipping season closes and "no-market" losses are reported for the first time since the strike. The trade expects a substantial buying movement with the close of the Lakes, however, and hopes that this tonnage will be absorbed with a minimum of price softening. The approach of cold weather always hastens purchases to augment reserves and, having delayed longer than usual this year, the consumer's re-entrance into the spot market is expected to prevent a slump in production.

Markets Tightening in Eastern Centers



On the other hand, Eastern centers already are experiencing tighter markets. Poor deliveries have boosted prices and inquiries are much stronger. Spot coal is scarce and premiums are paid for quick deliveries. Good grades from central Pennsylvania are finding a ready market and there is a growing production of prepared coal to fill the gap caused by the anthracite shortage. New York, Philadelphia and Baltimore all report a stronger demand for industrial coals. Conditions in New England are improving and although there is no broad inquiry as yet, the reduced receipts from Hampton Roads have increased Southern coal prices and strengthened the position of the all-rail shippers.
